

Classical Electrodynamics

Second Edition
J. D. JACKSON

Vector Formulas

$$\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c}) = \mathbf{b} \cdot (\mathbf{c} \times \mathbf{a}) = \mathbf{c} \cdot (\mathbf{a} \times \mathbf{b})$$

$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}$$

$$(\mathbf{a} \times \mathbf{b}) \cdot (\mathbf{c} \times \mathbf{d}) = (\mathbf{a} \cdot \mathbf{c})(\mathbf{b} \cdot \mathbf{d}) - (\mathbf{a} \cdot \mathbf{d})(\mathbf{b} \cdot \mathbf{c})$$

$$\nabla \times \nabla \psi = 0$$

$$\nabla \cdot (\nabla \times \mathbf{a}) = 0$$

$$\nabla \times (\nabla \times \mathbf{a}) = \nabla(\nabla \cdot \mathbf{a}) - \nabla^2 \mathbf{a}$$

$$\nabla \cdot (\psi \mathbf{a}) = \mathbf{a} \cdot \nabla \psi + \psi \nabla \cdot \mathbf{a}$$

$$\nabla \times (\psi \mathbf{a}) = \nabla \psi \times \mathbf{a} + \psi \nabla \times \mathbf{a}$$

$$\nabla(\mathbf{a} \cdot \mathbf{b}) = (\mathbf{a} \cdot \nabla)\mathbf{b} + (\mathbf{b} \cdot \nabla)\mathbf{a} + \mathbf{a} \times (\nabla \times \mathbf{b}) + \mathbf{b} \times (\nabla \times \mathbf{a})$$

$$\nabla \cdot (\mathbf{a} \times \mathbf{b}) = \mathbf{b} \cdot (\nabla \times \mathbf{a}) - \mathbf{a} \cdot (\nabla \times \mathbf{b})$$

$$\nabla \times (\mathbf{a} \times \mathbf{b}) = \mathbf{a}(\nabla \cdot \mathbf{b}) - \mathbf{b}(\nabla \cdot \mathbf{a}) + (\mathbf{b} \cdot \nabla)\mathbf{a} - (\mathbf{a} \cdot \nabla)\mathbf{b}$$

If \mathbf{x} is the coordinate of a point with respect to some origin, with magnitude $r = |\mathbf{x}|$, and $\mathbf{n} = \mathbf{x}/r$ is a unit radial vector, then

$$\nabla \cdot \mathbf{x} = 3 \quad \nabla \times \mathbf{x} = 0$$

$$\nabla \cdot \mathbf{n} = \frac{2}{r} \quad \nabla \times \mathbf{n} = 0$$

$$(\mathbf{a} \cdot \nabla)\mathbf{n} = \frac{1}{r} [\mathbf{a} - \mathbf{n}(\mathbf{a} \cdot \mathbf{n})] \equiv \frac{\mathbf{a}_\perp}{r}$$

Theorems from Vector Calculus

In the following ϕ , ψ , and \mathbf{A} are well-behaved scalar or vector functions, V is a three-dimensional volume with volume element d^3x , S is a closed two-dimensional surface bounding V , with area element da and unit outward normal \mathbf{n} at da .

$$\int_V \nabla \cdot \mathbf{A} d^3x = \int_S \mathbf{A} \cdot \mathbf{n} da \quad (\text{Divergence theorem})$$

$$\begin{aligned} \int_V \nabla \psi d^3x &= \int_S \psi \mathbf{n} da \\ \int_V \nabla \times \mathbf{A} d^3x &= \int_S \mathbf{n} \times \mathbf{A} da \end{aligned}$$

$$\int_V (\phi \nabla^2 \psi + \nabla \phi \cdot \nabla \psi) d^3x = \int_S \phi \mathbf{n} \cdot \nabla \psi da \quad (\text{Green's first identity})$$

$$\int_V (\phi \nabla^2 \psi - \psi \nabla^2 \phi) d^3x = \int_S (\phi \nabla \psi - \psi \nabla \phi) \cdot \mathbf{n} da \quad (\text{Green's theorem})$$

In the following S is an open surface and C is the contour bounding it, with line element $d\mathbf{l}$. The normal \mathbf{n} to S is defined by the right-hand side rule in relation to the sense of the line integral around C .

$$\int_S (\nabla \times \mathbf{A}) \cdot \mathbf{n} da = \oint_C \mathbf{A} \cdot d\mathbf{l} \quad (\text{Stokes's theorem})$$

$$\int_S \mathbf{n} \times \nabla \psi da = \oint_C \psi d\mathbf{l}$$

*To the memory of my father,
Walter David Jackson*

Preface

In the thirteen years since the appearance of the first edition, my interest in classical electromagnetism has waxed and waned, but never fallen to zero. The subject is ever fresh. There are always important new applications and examples. The present edition reflects two efforts on my part: the refinement and improvement of material already in the first edition; the addition of new topics (and the omission of a few).

The major purposes and emphasis are still the same, but there are extensive changes and additions. A major augmentation is the "Introduction and Survey" at the beginning. Topics such as the present experimental limits on the mass of the photon and the status of linear superposition are treated there. The aim is to provide a survey of those basics that are often assumed to be well known when one writes down the Maxwell equations and begins to solve specific examples. Other major changes in the first half of the book include a new treatment of the derivation of the equations of macroscopic electromagnetism from the microscopic description; a discussion of symmetry properties of mechanical and electromagnetic quantities; sections on magnetic monopoles and the quantization condition of Dirac; Stokes's polarization parameters; a unified discussion of the frequency dispersion characteristics of dielectrics, conductors, and plasmas; a discussion of causality and the Kramers-Kronig dispersion relations; a simplified, but still extensive, version of the classic Sommerfeld-Brillouin problem of the arrival of a signal in a dispersive medium (recently verified experimentally); an unusual example of a resonant cavity; the normal-mode expansion of an arbitrary field in a wave guide; and related discussions of sources in a guide or cavity and the transmission and reflection coefficients of flat obstacles in wave guides.

Chapter 9, on simple radiating systems and diffraction, has been enlarged to include scattering at long wavelengths (the blue sky, for example) and the optical theorem. The sections on scalar and vectorial diffraction have been improved.

Chapters 11 and 12, on special relativity, have been rewritten almost completely. The old pseudo-Euclidean metric with $x_4 = ict$ has been replaced by $g^{\mu\nu}$ (with $g^{00} = +1$, $g^{ii} = -1$, $i = 1, 2, 3$). The change of metric necessitated a complete revision and thus permitted substitution of modern experiments and concerns about the experimental basis of the special theory for the time-honored aberration of starlight and the Michelson-Morley experiment. Other aspects have been modernized, too. The extensive treatment of relativistic kinematics of the first edition has been relegated to the problems. In its stead is a discussion of the Lagrangian for the electromagnetic fields, the canonical and symmetric stress-energy tensor, and the Proca Lagrangian for massive photons.

Significant alterations in the remaining chapters include a new section on transition radiation, a completely revised (and much more satisfactory) semiclassical treatment of radiation emitted in collisions that stresses momentum transfer instead of impact parameter, and a better derivation of the coupling of multipole fields to their sources. The collection of formulas and page references to special functions on the front and back flyleaves is a much requested addition. Of the 278 problems, 117 (more than 40 per cent) are new.

The one area that remains almost completely unchanged is the chapter on magnetohydrodynamics and plasma physics. I regret this. But the book obviously has grown tremendously, and there are available many books devoted exclusively to the subject of plasmas or magnetohydrodynamics.

Of minor note is the change from Maxwell's equations and a Green's function to the Maxwell equations and a Green function. The latter boggles some minds, but is in conformity with other usage (Bessel function, for example). It is still Green's theorem, however, because that's whose theorem it is.

Work on this edition began in earnest during the first half of 1970 on the occasion of a sabbatical leave spent at Clare Hall and the Cavendish Laboratory in Cambridge. I am grateful to the University of California for the leave and indebted to N. F. Mott for welcoming me as a visitor to the Cavendish Laboratory and to R. J. Eden and A. B. Pippard for my appointment as a Visiting Fellow of Clare Hall. Tangible and intangible evidence at the Cavendish of Maxwell, Rayleigh and Thomson provided inspiration for my task; the stimulation of everyday activities there provided necessary diversion.

This new edition has benefited from questions, suggestions, comments and criticism from many students, colleagues, and strangers. Among those to whom I owe some specific debt of gratitude are A. M. Bincer, L. S. Brown, R. W. Brown, E. U. Condon, H. H. Denman, S. Deser, A. J. Dragt, V. L. Fitch, M. B. Halpern, A. Hobson, J. P. Hurley, D. L. Judd, L. T. Kerth, E. Marx, M. Nauenberg, A. B. Pippard, A. M. Portis, R. K. Sachs, W. M. Saslow, R. Schleif, V. L. Telegdi, T. Tredon, E. P. Tryon, V. F. Weisskopf, and Dudley Williams. Especially helpful were D. G. Boulware, R. N. Cahn, Leverett Davis, Jr., K. Gottfried, C. K. Graham, E. M. Purcell, and E. H. Wichmann. I send my thanks and fraternal greetings to all of these people, to the other readers who have written to me, and

the countless students who have struggled with the problems (and sometimes written asking for solutions to be dispatched before some deadline!). To my mind, the book is better than ever. May each reader benefit and enjoy!

Berkeley, California, 1974

J. D. JACKSON

Preface to the First Edition

Classical electromagnetic theory, together with classical and quantum mechanics, forms the core of present-day theoretical training for undergraduate and graduate physicists. A thorough grounding these subjects is a requirement for more advanced or specialized training.

Typically the undergraduate program in electricity and magnetism involves two or perhaps three semesters beyond elementary physics, with the emphasis on the fundamental laws, laboratory verification and elaboration of their consequences, circuit analysis, simple wave phenomena, and radiation. The mathematical tools utilized include vector calculus, ordinary differential equations with constant coefficients, Fourier series, and perhaps Fourier or Laplace transforms, partial differential equations, Legendre polynomials, and Bessel functions.

As a general rule a two-semester course in electromagnetic theory is given to beginning graduate students. It is for such a course that my book is designed. My aim in teaching a graduate course in electromagnetism is at least threefold. The first aim is to present the basic subject matter as a coherent whole, with emphasis on the unity of electric and magnetic phenomena, both in their physical basis and in the mode of mathematical description. The second, concurrent aim is to develop and utilize a number of topics in mathematical physics which are useful in both electromagnetic theory and wave mechanics. These include Green's theorems and Green's functions, orthonormal expansions, spherical harmonics, cylindrical and spherical Bessel functions. A third and perhaps most important purpose is the presentation of new material, especially on the interaction of relativistic charged particles with electromagnetic fields. In this last area personal preferences and prejudices enter strongly. My choice of topics is governed by what I feel is important and useful for students interested in theoretical physics, experimental nuclear and high-energy physics, and that as yet ill-defined field of plasma physics.

The book begins in the traditional manner with electrostatics. The first six

chapters are devoted to the development of Maxwell's theory of electromagnetism. Much of the necessary mathematical apparatus is constructed along the way, especially in Chapters 2 and 3, where boundary-value problems are discussed thoroughly. The treatment is initially in terms of the electric field E and the magnetic induction B , with the derived macroscopic quantities, D and H , introduced by suitable averaging over ensembles of atoms or molecules. In the discussion of dielectrics, simple classical models for atomic polarizability are described, but for magnetic materials no such attempt is made. Partly this omission was a question of space, but truly classical models of magnetic susceptibility are not possible. Furthermore, elucidation of the interesting phenomenon of ferromagnetism needs almost a book in itself.

The next three chapters (7-9) illustrate various electromagnetic phenomena, mostly of a macroscopic sort. Plane waves in different media, including plasmas as well as dispersion and the propagation of pulses, are treated in Chapter 7. The discussion of wave guides and cavities in Chapter 8 is developed for systems of arbitrary cross section, and the problems of attenuation in guides and the Q of a cavity are handled in a very general way which emphasizes the physical processes involved. The elementary theory of multipole radiation from a localized source and diffraction occupy Chapter 9. Since the simple scalar theory of diffraction is covered in many optics textbooks, as well as undergraduate books on electricity and magnetism, I have presented an improved, although still approximate, theory of diffraction based on vector rather than scalar Green's theorems.

The subject of magnetohydrodynamics and plasmas receives increasingly more attention from physicists and astrophysicists. Chapter 10 represents a survey of this complex field with an introduction to the main physical ideas involved.

The first nine or ten chapters constitute the basic material of classical electricity and magnetism. A graduate student in physics may be expected to have been exposed to much of this material, perhaps at a somewhat lower level, as an undergraduate. But he obtains a more mature view of it, understands it more deeply, and gains a considerable technical ability in analytic methods of solution when he studies the subject at the level of this book. He is then prepared to go on to more advanced topics. The advanced topics presented here are predominantly those involving the interaction of charged particles with each other and with electromagnetic fields, especially when moving relativistically.

The special theory of relativity had its origins in classical electrodynamics. And even after almost 60 years, classical electrodynamics still impresses and delights as a beautiful example of the covariance of physical laws under Lorentz transformations. The special theory of relativity is discussed in Chapter 11, where all the necessary formal apparatus is developed, various kinematic consequences are explored, and the covariance of electrodynamics is established. The next chapter is devoted to relativistic particle kinematics and dynamics. Although the dynamics of charged particles in electromagnetic fields

can properly be considered electrodynamics, the reader may wonder whether such things as kinematic transformations of collision problems can. My reply is that these examples occur naturally once one has established the four-vector character of a particle's momentum and energy, that they serve as useful practice in manipulating Lorentz transformations, and that the end results are valuable and often hard to find elsewhere.

Chapter 13 on collisions between charged particles emphasizes energy loss and scattering and develops concepts of use in later chapters. Here for the first time in the book I use semiclassical arguments based on the uncertainty principle to obtain approximate quantum-mechanical expressions for energy loss, etc., from the classical results. This approach, so fruitful in the hands of Niels Bohr and E. J. Williams, allows one to see clearly how and when quantum-mechanical effects enter to modify classical considerations.

The important subject of emission of radiation by accelerated point charges is discussed in detail in Chapters 14 and 15. Relativistic effects are stressed, and expressions for the frequency and angular dependence of the emitted radiation are developed in sufficient generality for all applications. The examples treated range from synchrotron radiation to bremsstrahlung and radiative beta processes. Cherenkov radiation and the Weizsäcker-Williams method of virtual quanta are also discussed. In the atomic and nuclear collision processes semiclassical arguments are again employed to obtain approximate quantum-mechanical results. I lay considerable stress on this point because I feel that it is important for the student to see that radiative effects such as bremsstrahlung are almost entirely classical in nature, even though involving small-scale collisions. A student who meets bremsstrahlung for the first time as an example of a calculation in quantum field theory will not understand its physical basis.

Multipole fields form the subject matter of Chapter 16. The expansion of scalar and vector fields in spherical waves is developed from first principles with no restrictions as to the relative dimensions of source and wavelength. Then the properties of electric and magnetic multipole radiation fields are considered. Once the connection to the multipole moments of the source has been made, examples of atomic and nuclear multipole radiation are discussed, as well as a macroscopic source whose dimensions are comparable to a wavelength. The scattering of a plane electromagnetic wave by a spherical object is treated in some detail in order to illustrate a boundary-value problem with vector spherical waves.

In the last chapter the difficult problem of radiative reaction is discussed. The treatment is physical, rather than mathematical, with the emphasis on delimiting the areas where approximate radiative corrections are adequate and on finding where and why existing theories fail. The original Abraham-Lorentz theory of the self-force is presented, as well as more recent classical considerations.

The book ends with an appendix on units and dimensions and a bibliography. In the appendix I have attempted to show the logical steps involved in setting up

a system of units, without haranguing the reader as to the obvious virtues of my choice of units. I have provided two tables which I hope will be useful, one for converting equations and symbols and the other for converting a given quantity of something from so many Gaussian units to so many mks units, and vice versa. The bibliography lists books which I think the reader may find pertinent and useful for reference or additional study. These books are referred to by author's name in the reading lists at the end of each chapter.

This book is the outgrowth of a graduate course in classical electrodynamics which I have taught off and on over the past eleven years, at both the University of Illinois and McGill University. I wish to thank my colleagues and students at both institutions for countless helpful remarks and discussions. Special mention must be made of Professor P. R. Wallace of McGill, who gave me the opportunity and encouragement to teach what was then a rather unorthodox course in electromagnetism, and Professors H. W. Wyld and G. Ascoli of Illinois, who have been particularly free with many helpful suggestions on the treatment of various topics. My thanks are also extended to Dr. A. N. Kaufman for reading and commenting on a preliminary version of the manuscript, and to Mr. G. L. Kane for his zealous help in preparing the index.

Contents

Introduction and Survey	1
1.1 Maxwell Equations in Vacuum, Fields, and Sources	2
1.2 The Inverse Square Law or the Mass of the Photon	5
1.3 Linear Superposition	10
1.4 The Maxwell Equations in Macroscopic Media	13
1.5 Boundary Conditions at Interfaces between Different Media	17
1.6 Some Remarks on Idealizations in Electromagnetism	22
References and Suggested Reading	25
 Chapter 1. Introduction to Electrostatics	 27
1.1 Coulomb's Law	27
1.2 Electric Field	28
1.3 Gauss's Law	30
1.4 Differential Form of Gauss's Law	32
1.5 Another Equation of Electrostatics and the Scalar Potential	33
1.6 Surface Distributions of Charges and Dipoles and Discontinuities in the Electric Field and Potential	35
1.7 Poisson and Laplace Equations	38
1.8 Green's Theorem	40
1.9 Uniqueness of the Solution with Dirichlet or Neumann Boundary Conditions	42
1.10 Formal Solution of Electrostatic Boundary-Value Problem with Green Function	43
1.11 Electrostatic Potential Energy and Energy Density, Capacitance	45
References and Suggested Reading	49
Problems	49
 Chapter 2. Boundary-Value Problems in Electrostatics: I	 54
2.1 Method of Images	54
2.2 Point Charge in the Presence of a Grounded Conducting Sphere	55
2.3 Point Charge in the Presence of a Charged, Insulated, Conducting Sphere	58
2.4 Point Charge Near a Conducting Sphere at Fixed Potential	60
2.5 Conducting Sphere in a Uniform Electric Field by the Method of Images	60
2.6 Green Function for the Sphere, General Solution for the Potential	62
2.7 Conducting Sphere with Hemispheres at Different Potentials	63
2.8 Orthogonal Functions and Expansions	65

2.9	Separation of Variables, Laplace Equation in Rectangular Coordinates	68
2.10	A Two-dimensional Potential Problem, Summation of a Fourier Series	71
2.11	Fields and Charge Densities in Two-dimensional Corners and Along Edges	75
	References and Suggested Reading	78
	Problems	79

Chapter 3. Boundary-Value Problems in Electrostatics: II **84**

3.1	Laplace Equation in Spherical Coordinates	84
3.2	Legendre Equation and Legendre Polynomials	85
3.3	Boundary-Value Problems with Azimuthal Symmetry	90
3.4	Behavior of Fields in a Conical Hole or near a Sharp Point	94
3.5	Associated Legendre Functions and the Spherical Harmonics $Y_{lm}(\theta, \phi)$	98
3.6	Addition Theorem for Spherical Harmonics	100
3.7	Laplace Equation in Cylindrical Coordinates, Bessel Functions	102
3.8	Boundary-Value Problems in Cylindrical Coordinates	108
3.9	Expansion of Green Functions in Spherical Coordinates	110
3.10	Solution of Potential Problems with Spherical Green Function Expansion	113
3.11	Expansion of Green Functions in Cylindrical Coordinates	116
3.12	Eigenfunction Expansions for Green Functions	119
3.13	Mixed Boundary Conditions, Conducting Plane with a Circular Hole	121
	References and Suggested Reading	127
	Problems	128

Chapter 4. Multipoles, Electrostatics of Macroscopic Media, Dielectrics **136**

4.1	Multipole Expansion	136
4.2	Multipole Expansion of the Energy of a Charge Distribution in an External Field	142
4.3	Elementary Treatment of Electrostatics with Ponderable Media	143
4.4	Boundary-Value Problems with Dielectrics	147
4.5	Molecular Polarizability and Electric Susceptibility	152
4.6	Models for the Molecular Polarizability	155
4.7	Electrostatic Energy in Dielectric Media	158
	References and Suggested Reading	163
	Problems	163

Chapter 5. Magnetostatics **168**

5.1	Introduction and Definitions	168
5.2	Biot and Savart Law	169

5.3	The Differential Equations of Magnetostatics and Ampère's Law	173
5.4	Vector Potential	175
5.5	Vector Potential and Magnetic Induction for a Circular Current Loop	177
5.6	Magnetic Fields of a Localized Current Distribution, Magnetic Moment	180
5.7	Force and Torque on and Energy of a Localized Current Distribution in an External Magnetic Induction	184
5.8	Macroscopic Equations, Boundary Conditions on B and H	187
5.9	Methods of Solving Boundary-Value Problems in Magnetostatics	191
5.10	Uniformly Magnetized Sphere	194
5.11	Magnetized Sphere in an External Field, Permanent Magnets	197
5.12	Magnetic Shielding, Spherical Shell of Permeable Material in a Uniform Field	199
5.13	Effect of a Circular Hole in a Perfectly Conducting Plane with an Asymptotically Uniform Tangential Magnetic Field on One Side	201
	References and Suggested Reading	204
	Problems	205

Chapter 6. Time-Varying Fields, Maxwell Equations, Conservation Laws **209**

6.1	Faraday's Law of Induction	210
6.2	Energy in the Magnetic Field	213
6.3	Maxwell's Displacement Current, Maxwell Equations	217
6.4	Vector and Scalar Potentials	219
6.5	Gauge Transformations, Lorentz Gauge, Coulomb Gauge	220
6.6	Green Functions for the Wave Equation	223
6.7	Derivation of the Equations of Macroscopic Electromagnetism	226
6.8	Poynting's Theorem and Conservation of Energy and Momentum for a System of Charged Particles and Electromagnetic Fields	236
6.9	Conservation Laws for Macroscopic Media	240
6.10	Poynting's Theorem for Harmonic Fields, Field Definitions of Impedance and Admittance	241
6.11	Transformation Properties of Electromagnetic Fields and Sources under Rotations, Spatial Reflections, and Time Reversal	245
6.12	On the Question of Magnetic Monopoles	251
6.13	Discussion of the Dirac Quantization Condition	254
	References and Suggested Reading	260
	Problems	261

Chapter 7. Plane Electromagnetic Waves and Wave Propagation **269**

7.1	Plane Waves in a Nonconducting Medium	269
7.2	Linear and Circular Polarization, Stokes Parameters	273

7.3	Reflection and Refraction of Electromagnetic Waves at a Plane Interface between Dielectrics	278
7.4	Polarization by Reflection and Total Internal Reflection	282
7.5	Frequency Dispersion Characteristics of Dielectrics, Conductors, and Plasmas	284
7.6	Simplified Model of Propagation in the Ionosphere and Magnetosphere	292
7.7	Waves in a Conducting or Dissipative Medium	296
7.8	Superposition of Waves in One Dimension, Group Velocity	299
7.9	Illustration of the Spreading of a Pulse as It Propagates in a Dispersive Medium	303
7.10	Causality in the Connection between D and E , Kramers-Kronig Relations	306
7.11	Arrival of a Signal After Propagation Through a Dispersive Medium	313
	References and Suggested Reading	326
	Problems	327

Chapter 8. Wave Guides and Resonant Cavities 334

8.1	Fields at the Surface of and within a Conductor	335
8.2	Cylindrical Cavities and Wave Guides	339
8.3	Wave Guides	343
8.4	Modes in a Rectangular Wave Guide	345
8.5	Energy Flow and Attenuation in Wave Guides	346
8.6	Perturbation of Boundary Conditions	350
8.7	Resonant Cavities	353
8.8	Power Losses in a Cavity, <i>Q</i> of a Cavity	356
8.9	Earth and Ionosphere as a Resonant Cavity, Schumann Resonances	360
8.10	Dielectric Wave Guides	364
8.11	Expansion in Normal Modes, Fields Generated by a Localized Source in Guide	369
8.12	Reflection and Transmission by Plane Diaphragms, Variational Approximation	375
8.13	Impedance of a Flat Strip Parallel to the Electric Field in a Rectangular Wave Guide	380
	References and Suggested Reading	384
	Problems	385

Chapter 9. Simple Radiating Systems, Scattering, and Diffraction 391

9.1	Fields and Radiation of a Localized Oscillating Source	391
9.2	Electric Dipole Fields and Radiation	394
9.3	Magnetic Dipole and Electric Quadrupole Fields	397
9.4	Center-fed Linear Antenna	401
9.5	Multipole Expansion for Localized Source or Aperture in Wave Guide	405

9.6	Scattering at Long Wavelengths	411
9.7	Perturbation Theory of Scattering, Rayleigh's Explanation of the Blue Sky, Scattering by Gases and Liquids	418
9.8	Scalar Diffraction Theory	427
9.9	Vector Equivalents of Kirchhoff Integral	432
9.10	Vectorial Diffraction Theory	435
9.11	Babinet's Principle of Complementary Screens	438
9.12	Diffraction by a Circular Aperture, Remarks on Small Apertures	441
9.13	Scattering in the Short-Wavelength Limit	447
9.14	Optical Theorem and Related Matters	453
	References and Suggested Reading	459
	Problems	460

Chapter 10. Magnetohydrodynamics and Plasma Physics **469**

10.1	Introduction and Definitions	469
10.2	Magnetohydrodynamic Equations	471
10.3	Magnetic Diffusion, Viscosity, and Pressure	472
10.4	Magnetohydrodynamic Flow between Boundaries with Crossed Electric and Magnetic Fields	475
10.5	Pinch Effect	479
10.6	Instabilities in a Pinched Plasma Column	482
10.7	Magnetohydrodynamic Waves	485
10.8	Plasma Oscillations	490
10.9	Short-wavelength Limit on Plasma Oscillations and the Debye Screening Distance	494
	References and Suggested Reading	497
	Problems	498

Chapter 11. Special Theory of Relativity **503**

11.1	The Situation before 1900, Einstein's Two Postulates	504
11.2	Some Recent Experiments	507
11.3	Lorentz Transformations and Basic Kinematic Results of Special Relativity	515
11.4	Addition of Velocities, Four-Velocity	522
11.5	Relativistic Momentum and Energy of a Particle	525
11.6	Mathematical Properties of the Space-Time of Special Relativity	532
11.7	Matrix Representation of Lorentz Transformations, Infinitesimal Generators	536
11.8	Thomas Precession	541
11.9	Invariance of Electric Charge, Covariance of Electrodynamics	547
11.10	Transformation of Electromagnetic Fields	552
11.11	Relativistic Equation of Motion for Spin in Uniform or Slowly Varying External Fields	556

11.12	Note on Notation and Units in Relativistic Kinematics	560
	References and Suggested Reading	561
	Problems	562

Chapter 12. Dynamics of Relativistic Particles and Electromagnetic Fields **571**

12.1	Lagrangian and Hamiltonian for a Relativistic Charged Particle in External Electromagnetic Fields	572
12.2	On the Question of Obtaining the Magnetic Field, Magnetic Force, and the Maxwell Equations from Coulomb's law and Special Relativity	578
12.3	Motion in a Uniform, Static, Magnetic Field	581
12.4	Motion in Combined Uniform, Static, Electric and Magnetic Fields	582
12.5	Particle Drifts in Nonuniform, Static Magnetic Fields	584
12.6	Adiabatic Invariance of Flux through Orbit of Particle	588
12.7	Lowest-Order Relativistic Corrections to the Lagrangian for Interacting Charged Particles, the Darwin Lagrangian	593
12.8	Lagrangian for the Electromagnetic Field	595
12.9	Proca Lagrangian, Photon Mass Effects	597
12.10	Canonical and Symmetric Stress Tensors, Conservation Laws	601
12.11	Solution of the Wave Equation in Covariant Form, Invariant Green Functions	608
	References and Suggested Reading	612
	Problems	613

Chapter 13. Collisions between Charged Particles, Energy Loss, and Scattering **618**

13.1	Energy Transfer in a Coulomb Collision	619
13.2	Energy Transfer to a Harmonically Bound Charge	623

Introduction and Survey

Classical Electrodynamics

Introduction and Survey

Although amber and lodestone were known to the ancient Greeks, electrodynamics developed as a quantitative subject in less than a hundred years. Cavendish's remarkable experiments in electrostatics were done from 1771 to 1773. Coulomb's monumental researches began to be published in 1785. This marked the beginning of quantitative research in electricity and magnetism on a worldwide scale. Fifty years later Faraday was studying the effects of time-varying currents and magnetic fields. By 1864 Maxwell had published his famous paper on a dynamical theory of the electromagnetic field.

The story of the development of our understanding of electricity and magnetism and of light is, of course, much longer and richer than the mention of a few names from one century would indicate. For a detailed account of the fascinating history, the reader should consult the authoritative volumes by Whittaker.* A briefer account, with emphasis on optical phenomena, appears at the beginning of *Born and Wolf*.

This book is self-contained in that, though some mathematical background (vector calculus, differential equations) is assumed, the subject of electrodynamics is developed from its beginnings in electrostatics. Most readers are not coming to the subject for the first time, however. The purpose of this introduction is therefore not to set the stage for a discussion of Coulomb's law and other basics, but rather to present a review and a survey of classical electromagnetism. Questions such as the current accuracy of the inverse square law of force (mass of the photon), the limits of validity of the principle of linear superposition, the effects of discreteness of charge and of energy differences are discussed. "Bread and butter" topics such as the boundary conditions for macroscopic fields at surfaces between different media and at conductors are also treated. The aim is to set classical electromagnetism in context, to indicate

* Italicized surnames are used to denote books that are cited fully in the Bibliography.

its domain of validity, and to elucidate some of the idealizations that it contains. Some results from later in the book and some nonclassical ideas are used in the course of the discussion. Certainly a reader beginning electromagnetism for the first time will not follow all the arguments or see their significance. It is intended, however, that for others this introduction will serve as a springboard into the later parts of the book, beyond Chapter 5, as well as a reminder of how the subject stands as an experimental science.

I.1 Maxwell Equations in Vacuum, Fields, and Sources

The equations governing electromagnetic phenomena are the Maxwell equations, which for sources in vacuum are

$$\begin{aligned}
 \nabla \cdot \mathbf{E} &= 4\pi\rho \\
 \nabla \times \mathbf{B} - \frac{1}{c} \frac{\partial \mathbf{E}}{\partial t} &= \frac{4\pi}{c} \mathbf{J} \\
 \nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} &= 0 \\
 \nabla \cdot \mathbf{B} &= 0
 \end{aligned} \tag{I.1}$$

Implicit in the Maxwell equations is the continuity equation for charge density and current density,

$$\frac{\partial \rho}{\partial t} + \nabla \cdot \mathbf{J} = 0 \tag{I.2}$$

This follows from combining the time derivative of the first equation in (I.1) with the divergence of the second equation. Also essential for consideration of charged particle motion is the Lorentz force equation,

$$\mathbf{F} = q \left(\mathbf{E} + \frac{\mathbf{v}}{c} \times \mathbf{B} \right) \tag{I.3}$$

that gives the force acting on a point charge q in the presence of electromagnetic fields.

These equations have been written in Gaussian units, the system of electromagnetic units used in this book. (Units and dimensions are discussed in the Appendix.) The Maxwell equations are displayed in the commoner systems of units in Table 2 of the Appendix. Apart from the fields \mathbf{E} and \mathbf{B} and the sources ρ and \mathbf{J} , the equations involve a parameter c . This quantity has the dimensions of velocity and is the speed of light in vacuum. It is fundamental to all electromagnetic and relativistic phenomena. Based on our units of length and time, presently defined separately in terms of two different atomic transitions, as

discussed in the Appendix, this parameter has the empirical value

$$c = 299,792,456.2 \pm 1.1 \text{ meters/second}^*$$

This result comes from an experiment using a highly stabilized helium-neon laser in which both the frequency and the wavelength were measured ($3.39 \mu\text{m}$ methane-stabilized line). In passing we note that the precision here is such that the present definition of the meter is likely to be replaced by one using c and the second. Other evidence [see Section 11.2(c)] indicates that to high accuracy the speed of light in vacuum is independent of frequency from very low frequencies to at least $\nu \approx 10^{24} \text{ Hz}$ (4 GeV photons). For most practical purposes we can approximate $c \approx 3 \times 10^8 \text{ m/sec}$ or to be considerably more accurate, $c = 2.998 \times 10^8 \text{ m/sec}$.

The electric and magnetic fields \mathbf{E} and \mathbf{B} in (I.1) were originally introduced by means of the force equation (I.3). In Coulomb's experiments forces acting between localized distributions of charge were observed. There it is found useful (see Section 1.2) to introduce the electric field \mathbf{E} as the force per unit charge. Similarly, in Ampère's experiments the mutual forces of current-carrying loops were studied (see Section 5.2). With the identification of $NAq\mathbf{v}$ as a current in a conductor of cross-sectional area A with N charge carriers per unit volume moving at velocity \mathbf{v} , we see that \mathbf{B} in (I.3) is defined in magnitude as a force per unit current. Although \mathbf{E} and \mathbf{B} thus first appear just as convenient replacements for forces produced by distributions of charge and current, they have other important aspects. First, their introduction decouples conceptually the sources from the test bodies experiencing electromagnetic forces. If the fields \mathbf{E} and \mathbf{B} from two source distributions are the same at a given point in space, the force acting on a test charge or current at that point will be the same, regardless of how different the source distributions are. This gives \mathbf{E} and \mathbf{B} in (I.3) meaning in their own right, independent of the sources. Second, electromagnetic fields can exist in regions of space where there are no sources. They can carry energy, momentum, and angular momentum and so have an existence totally independent of charges and currents. In fact, though there are recurring attempts to eliminate explicit reference to the fields in favor of action-at-a-distance descriptions of the interaction of charged particles, the concept of the electromagnetic field is one of the most fruitful ideas of physics, both classically and quantum mechanically.

The concept of \mathbf{E} and \mathbf{B} as ordinary fields is a classical notion. It can be thought of as the classical limit (limit of large quantum numbers) of a quantum mechanical description in terms of real or virtual photons. In the domain of macroscopic phenomena and even some atomic phenomena the discrete photon aspect of the electromagnetic field can usually be ignored or at least glossed over. For example, 1 meter from a 100 watt light bulb, the root mean square

* K. Evenson et al., *Phys. Rev. Letters* **29**, 1346 (1972).

electric field is of the order of 0.5 volts/cm and there are of the order of 10^{15} visible photons/cm²×sec. Similarly, an isotropic FM antenna with a power of 100 watts at 10^8 Hz produces a r.m.s. electric field of only 5 microvolts/cm at a distance of 100 kilometers, but this still corresponds to a flux of 10^{12} photons/cm²×sec, or about 10^9 photons in a volume of 1 wavelength cubed (27 m^3) at that distance. Ordinarily an apparatus will not be sensible to the individual photons; the cumulative effect of many photons emitted or absorbed will appear as a continuous, macroscopically observable response. Then a completely classical description in terms of the Maxwell equations is permitted and is appropriate.

How is one to decide a priori when a classical description of the electromagnetic fields is adequate? Some sophistication is occasionally needed, but the following is usually a sufficient criterion: When the number of photons involved can be taken as large but the momentum carried by an individual photon is small compared to the momentum of the material system, then the response of the material system can be determined adequately from a classical description of the electromagnetic fields. For example, each 10^8 Hz photon emitted by our FM antenna gives it an impulse of only 2.2×10^{-34} newton-seconds. A classical treatment is surely adequate. Again, the scattering of light by a free electron is governed by the classical Thomson formula (Section 14.7) at low frequencies, but by the laws of the Compton effect as the momentum $\hbar\omega/c$ of the incident photon becomes significant compared to mc . The photoelectric effect is nonclassical for the matter system, since the quasi-free electrons in the metal change their individual energies by amounts equal to those of the absorbed photons, but the photoelectric current can be calculated quantum mechanically for the electrons using a classical description of the electromagnetic fields.

The quantum nature of the electromagnetic fields must, on the other hand, be taken into account in spontaneous emission of radiation by atoms, or by any other system where there are no photons present initially and only a small number of photons present finally. The average behavior may still be describable in essentially classical terms, basically because of conservation of energy and momentum. An example is the classical treatment (Section 17.2) of the cascading of a charged particle down through the orbits of an attractive potential. At high particle quantum numbers a classical description of particle motion is adequate, and the secular changes in energy and angular momentum can be calculated classically from the radiation reaction because the energies of the successive photons emitted are small compared to the kinetic or potential energy of the orbiting particle.

The sources in (I.1) are $\rho(\mathbf{x}, t)$, the electric charge density, and $\mathbf{J}(\mathbf{x}, t)$, the electric current density. In classical electromagnetism they are assumed to be continuous distributions in \mathbf{x} , although we consider from time to time localized distributions that can be approximated by points. The magnitudes of these point charges are assumed to be completely arbitrary, but are known to be restricted in

reality to discrete values. The basic unit of charge is the magnitude of the charge on the electron,

$$\begin{aligned}|q_e| &= 4.803250(21) \times 10^{-10} \text{ esu} \\ &= 1.6021917(70) \times 10^{-19} \text{ coulomb}\end{aligned}$$

where the errors in the last two decimal places are shown in parentheses. The charges on the proton and on all presently known particles or systems of particles are integral multiples of this basic unit. The experimental accuracy with which it is known that the multiples are exactly integers is phenomenal (better than 1 part in 10^{20}). The experiments are discussed in Section 11.9 where the question of the Lorentz invariance of charge is also treated.

The discreteness of electric charge does not need to be considered in most macroscopic applications. A 1 microfarad capacitor at a potential of 150 volts, for example, has a total of 10^{15} elementary charges on each electrode. A few thousand electrons more or less would not be noticed. A current of 1 microampere corresponds to 6.2×10^{12} elementary charges/second. There are, of course, some delicate macroscopic or almost macroscopic experiments in which the discreteness of charge enters. Millikan's famous oil drop experiment is one. His droplets were typically 10^{-4} cm in radius and had a few or few tens of elementary charges on them.

There is a lack of symmetry in the appearance of the source terms in Maxwell equations (I.1). The first two equations have sources; the second two do not. This reflects the experimental *absence of magnetic charges* and currents. Actually, as is shown in Section 6.12, particles could have magnetic as well as electric charge. If all particles in nature had the same ratio of magnetic to electric charge, the fields and sources could be redefined in such a way that the usual Maxwell equations (I.1) emerge. In this sense it is somewhat a matter of convention to say that no magnetic charges or currents exist. Throughout most of this book it is assumed that only electric charges and currents act in the Maxwell equations, but some consequences of the existence of a particle with a different magnetic to electric charge ratio, for example, a magnetic monopole, are described in Chapter 6.

I.2 The Inverse Square Law or the Mass of the Photon

The distance dependence of the electrostatic law of force was shown quantitatively by Cavendish and Coulomb to be an inverse square law. Through Gauss's law and the divergence theorem (see Sections 1.3 and 1.4) this leads to the first of the Maxwell equations (I.1). The original experiments had an accuracy of only a few percent and, furthermore, were at a laboratory length scale. Experiments at higher precision and involving different regimes of size have been performed

over the years. It is now customary to quote the tests of the inverse square law in one of two ways:

- (a) Assume that the force varies as $1/r^{2+\epsilon}$ and quote a value or limit for ϵ .
- (b) Assume that the electrostatic potential has the "Yukawa" form (see Section 12.9), $r^{-1}e^{-\mu r}$ and quote a value or limit for μ or μ^{-1} . Since $\mu = m_\gamma c/\hbar$, where m_γ is the assumed mass of the photon, the test of the inverse square law is sometimes phrased in terms of an upper limit on m_γ . Laboratory experiments usually give ϵ and perhaps μ or m_γ ; geomagnetic experiments give μ or m_γ .

The original experiment with concentric spheres by Cavendish* in 1772 gave an upper limit on ϵ of $|\epsilon| \leq 0.02$. His apparatus is shown in Fig. 1.1. About 100 years later Maxwell performed a very similar experiment at Cambridge† and set an upper limit of $|\epsilon| \leq 5 \times 10^{-5}$. Two other noteworthy laboratory experiments based on Gauss's law are those of Plimpton and Lawton,‡ which gave $|\epsilon| < 2 \times 10^{-9}$, and the recent one of Williams, Faller, and Hill.§ A schematic drawing of the apparatus of the latter experiment is shown in Fig. 1.2. Though not a static experiment ($\nu = 4 \times 10^6$ Hz), the basic idea is almost the same as Cavendish's. He looked for a charge on the inner sphere after it had been brought into electrical contact with the charged outer sphere and then disconnected; he found none. Williams, Faller, and Hill looked for a voltage difference between two concentric shells when the outer one was subjected to an alternating voltage of ± 10 kV with respect to ground. Their sensitivity was such that a voltage difference of less than 10^{-12} V could have been detected. Their null result, when interpreted by means of the Proca equations (Section 12.9), gives a limit of $\epsilon = (2.7 \pm 3.1) \times 10^{-16}$.

Measurements of the earth's magnetic field, both on the surface and out from the surface by satellite observation, permit the best limits to be set on ϵ or equivalently the photon mass m_γ . The geophysical and also the laboratory observations are discussed in the reviews by Kobzarev and Okun' and by Goldhaber and Nieto, listed at the end of this introduction. The surface measurements of the earth's magnetic field give slightly the best value (see Problem 12.14), namely,

$$m_\gamma < 4 \times 10^{-48} \text{ gm}$$

or

$$\mu^{-1} > 10^{10} \text{ cm}$$

For comparison, the electron mass is $m_e = 9.1 \times 10^{-28}$ gm. The laboratory experiment of Williams, Faller, and Hill can be interpreted as setting a limit $m_\gamma < 1.6 \times 10^{-47}$ gm, only a factor of 4 poorer than the geomagnetic limit.

Fig. 1.1 Cavendish's apparatus for establishing the inverse square law of electrostatics. Top, facsimile of Cavendish's own sketch; bottom, line drawing by a draughtsman. The inner globe is 12.1 inches in diameter, the hollow pasteboard hemispheres slightly larger. Both globe and hemispheres were covered with tinfoil "to make them the more perfect conductors of electricity." (Figures reproduced by permission of the Cambridge University Press.)

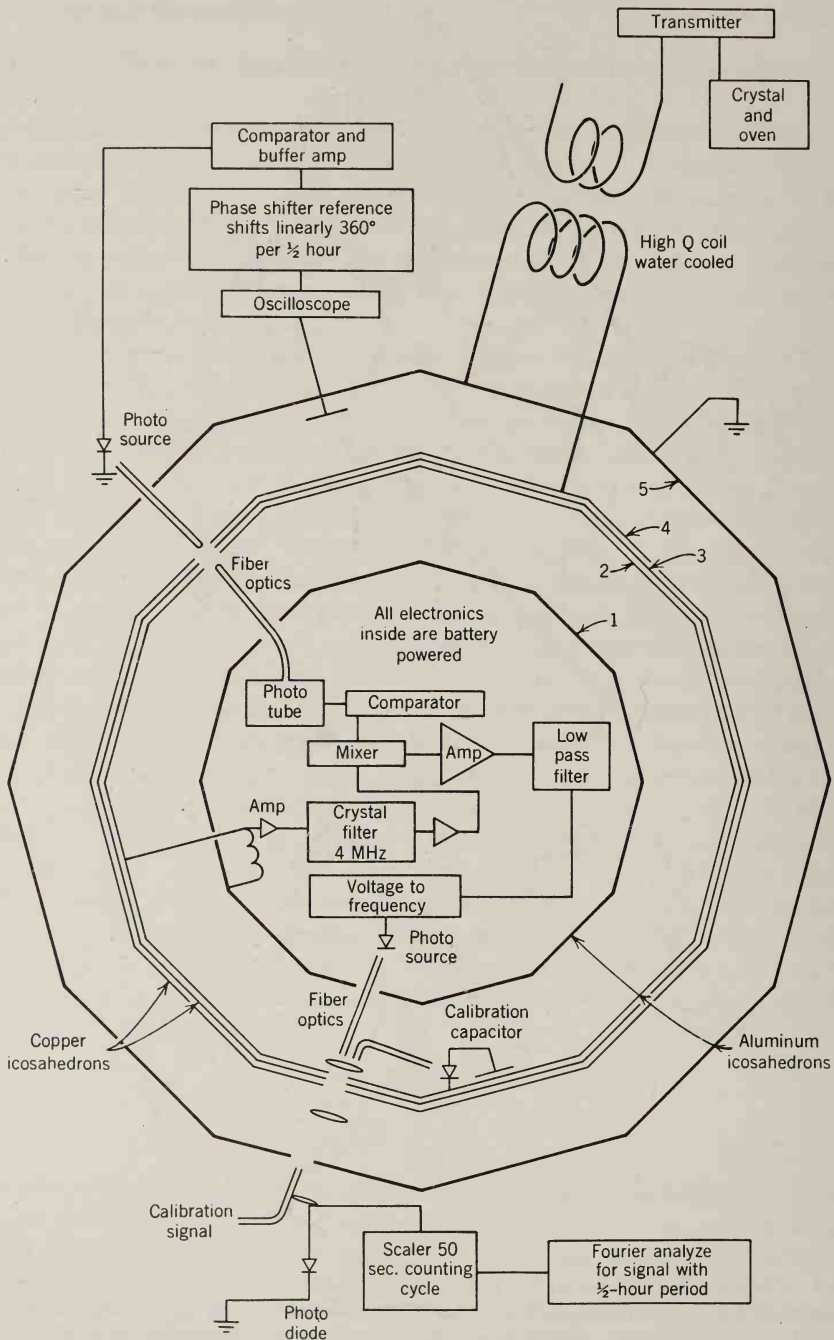

Fig. 1.2 Schematic diagram of the “Cavendish” experiment of Williams, Faller, and Hill. The concentric icosahedrons are conducting shells. A 4 MHz voltage of 10 kV peak is applied between shells 5 and 4. Shell 4 and its contiguous shells 2 and 3 are roughly 1.5

A rough limit on the photon mass can be set quite easily by noting the existence of very low frequency modes in the earth-ionosphere resonant cavity (Schumann resonances, discussed in Section 8.9). The double Einstein relation, $h\nu = m_\gamma c^2$, suggests that the photon mass must satisfy an inequality, $m_\gamma < h\nu_0/c^2$, where ν_0 is any electromagnetic resonant frequency. The lowest Schumann resonance has $\nu_0 \approx 8$ Hz. From this we calculate $m_\gamma < 6 \times 10^{-47}$ gm, a very small value only one order of magnitude above the best limit. While this argument has crude validity, more careful consideration (see Section 12.9 and the references given there) shows that the limit is roughly $(R/H)^{1/2} \approx 10$ times larger, $R \approx 6400$ km being the radius of the earth, and $H \approx 60$ km being the height of the ionosphere.* In spite of this dilution factor the limit of 10^{-45} gm set by the mere existence of Schumann resonances is quite respectable.

The laboratory and geophysical tests show that on length scales of order 1 to 10^9 cm, the inverse square law holds with extreme precision. At smaller distances we must turn to less direct evidence often involving additional assumptions. For example, Rutherford's historical analysis of the scattering of alpha particles by thin foils substantiates the Coulomb law of force down to distances of the order of 10^{-11} cm provided the alpha particle and the nucleus can be treated as classical point charges interacting statically and the charge cloud of the electrons can be ignored. All of these assumptions can be, and have been, tested, of course, but only within the framework of the validity of quantum mechanics, linear superposition (see below), and other (very reasonable) assumptions. At still smaller distances, relativistic quantum mechanics is necessary, and strong interaction effects enter to obscure the questions as well as the answers. Nevertheless, elastic scattering experiments with positive and negative electrons at center of mass energies of up to 5 GeV have shown that quantum electrodynamics (the relativistic theory of point electrons interacting with massless photons) holds to distances of the order of 10^{-15} cm. We conclude that the photon mass can be taken to be zero (the inverse square force law holds) over the whole classical range of distances and deep into the quantum domain as well. The inverse square law is known to hold over at least 24 orders of magnitude in the length scale!

* The basic point is that, to the extent that H/R is negligible, the ELF propagation is the same as in a parallel plate transmission line in the fundamental TEM mode. This propagation is unaffected by a finite photon mass, except through changes in the static capacitance and inductance per unit length. Explicit photon mass effects occur in order $(H/R)\mu^2$.

meters in diameter and contain shell 1 inside. The voltage difference between shells 1 and 2 (if any) appears across the inductor indicated at about 8 o'clock in shell 1. The amplifier and optics system are necessary to extract the voltage information to the outside world. They are equivalent to Cavendish's system of strings that automatically opened the hinged hemispheres and brought up the pith balls to test for charge on the inner sphere. (Figure reproduced with permission of the authors.)

I.3 Linear Superposition

The Maxwell equations in vacuum are *linear* in the fields \mathbf{E} and \mathbf{B} . This linearity is exploited so often, for example, with hundreds of different telephone conversations on a single microwave link, that it is taken for granted. There are, of course, circumstances where nonlinear effects occur—in magnetic materials, in crystals responding to intense laser beams, even in the devices used to put those telephone conversations on and off the microwave beam. But here we are concerned with fields in vacuum or the microscopic fields inside atoms and nuclei.

What evidence do we have to support the idea of linear superposition? At the macroscopic level, all sorts of experiments test linear superposition at the level of 0.1% accuracy—groups of charges and currents produce electric and magnetic forces calculable by linear superposition, transformers perform as expected, standing waves are observed on transmission lines—the reader can make a list. In optics, slit systems show diffraction patterns; X-ray diffraction tells us about crystal structure; white light is refracted by a prism into the colors of the rainbow and recombined into white light again. At the macroscopic and even at the atomic level, linear superposition is remarkably valid.

It is in the subatomic domain that departures from linear superposition can be legitimately sought. As charged particles approach each other very closely, electric field strengths become enormous. If we think of a charged particle as a localized distribution of charge, we see that its electromagnetic energy grows larger and larger as the charge is localized more and more. It is natural, in order to avoid infinite self-energies of point particles, to speculate that some sort of saturation occurs, that fields strengths have some upper bound. Such classical nonlinear theories have been studied in the past. One well-known example is the theory of Born and Infeld.* The vacuum is given electric and magnetic permeabilities,

$$\epsilon = \frac{1}{\mu} = \left[1 + \frac{1}{b^2} (B^2 - E^2) \right]^{-1/2} \quad (\text{I.4})$$

where b is a maximum field strength. Equation (I.4) is actually a simplified form proposed earlier by Born alone. It suffices to illustrate the general idea. Fields are obviously modified at short distances; all electromagnetic energies are finite. But such theories suffer from arbitrariness in the manner of how the nonlinearity occurs and also from grave problems with a transition to a quantum theory. Furthermore, there is no evidence of this kind of classical nonlinearity. The quantum mechanics of many-electron atoms is described to high precision by normal quantum theory with the interactions between nucleus and electrons and between electrons and electrons given by a *linear superposition* of pairwise potentials (or retarded relativistic interactions for fine effects). Field strengths of

* M. Born and L. Infeld, *Proc. Roy. Soc. A* **144**, 425 (1934). See M. Born, *Atomic Physics*, Blackie, London, Appendix VI, for an elementary discussion.

Fig. I.3 The scattering of light by light. Schematic diagram of the process by which photon-photon scattering occurs.

the order of 10^9 – 10^{15} volts/cm exist at the orbits of electrons in atoms, while the electric field at the edge of a heavy nucleus is of the order of 10^{19} volts/cm. Energy level differences in light atoms like helium, calculated on the basis of linear superposition of electromagnetic interactions, are in agreement with experiment to accuracies that approach 1 part in 10^6 . And Coulomb energies of heavy nuclei are consistent with linear superposition of electromagnetic effects. It is possible, of course, that for field strengths greater than 10^{19} volts/cm nonlinear effects could occur. One place to look for such effects is in superheavy nuclei ($Z > 110$), both in the atomic energy levels and in the nuclear Coulomb energy.* At the present time there is no evidence for any classical nonlinear behavior of vacuum fields at short distances.

There is a *quantum-mechanical nonlinearity* of electromagnetic fields that arises because the uncertainty principle permits the momentary creation of an electron-positron pair by two photons and the subsequent disappearance of the pair with the emission of two different photons, as indicated schematically in Fig. I.3. This process is called the scattering of light by light.† The two incident plane waves $e^{ik_1 \cdot x - i\omega_1 t}$ and $e^{ik_2 \cdot x - i\omega_2 t}$ do not merely add coherently, as expected with linear superposition, but interact and (with small probability) transform into two different plane waves with wave vectors k_3 and k_4 . This nonlinear feature of *quantum* electrodynamics can be expressed, at least for slowly varying fields, in

* An investigation of the effect of a Born-Infeld type of nonlinearity on the atomic energy levels in superheavy elements has been made by J. Rafelski, W. Greiner, and L. P. Fulcher, *Nuovo Cimento* **13B**, 135 (1973).

† When two of the photons in Fig. I.3 are virtual photons representing interaction to second order with a static nuclear Coulomb field, the process is known as Delbrück scattering. See Section 15.8 of J. M. Jauch and F. Rohrlich, *The Theory of Photons and Electrons*, Addison-Wesley, Reading, Mass. (1955).

terms of electric and magnetic permeability tensors of the vacuum:

$$D_i = \sum_k \epsilon_{ik} E_k, \quad B_i = \sum_k \mu_{ik} H_k$$

where

$$\left. \begin{aligned} \epsilon_{ik} &= \delta_{ik} + \frac{e^4 \hbar}{45 \pi m^4 c^7} [2(E^2 - B^2) \delta_{ik} + 7 B_i B_k] + \dots \\ \mu_{ik} &= \delta_{ik} + \frac{e^4 \hbar}{45 \pi m^4 c^7} [2(B^2 - E^2) \delta_{ik} + 7 E_i E_k] + \dots \end{aligned} \right\} \quad (I.5)$$

Here e and m are the charge and mass of the electron. These results were first obtained by Euler and Kockel in 1935.* We observe that in the classical limit ($\hbar \rightarrow 0$), these nonlinear effects go to zero. Comparison with the classical Born-Infeld expression (I.4) shows that for small nonlinearities, the quantum-mechanical field strength

$$b_q = \frac{\sqrt{45} \pi}{2} \sqrt{\frac{e^2}{\hbar c}} \frac{e}{r_0^2} \approx 0.51 \frac{e}{r_0^2}$$

plays a role analogous to the Born-Infeld parameter b . Here $r_0 = e^2/mc^2 \approx 2.8 \times 10^{-13}$ cm is the classical electron radius and $e/r_0^2 = 1.8 \times 10^{18}$ volts/cm is the electric field at the surface of such a classical electron. Two comments in passing: (a) the ϵ_{ik} and μ_{ik} in (I.5) are approximations that fail for field strengths approaching b_q or when the fields vary too rapidly in space or time (\hbar/mc setting the critical scale of length and \hbar/mc^2 of time); (b) the chance numerical coincidence of b_q and $e/2r_0^2$ is suggestive, but probably not significant since b_q involves Planck's constant \hbar .

In analogy with the polarization $\mathbf{P} = (\mathbf{D} - \mathbf{E})/4\pi$, we speak of the field-dependent terms in (I.5) as *vacuum polarization* effects. In addition to the scattering of light by light or Delbrück scattering, vacuum polarization causes very small shifts in atomic energy levels. The dominant contribution involves a virtual electron-positron pair, just as in Fig. I.3, but with only two photon lines instead of four. If the photons are real, the process contributes to the mass of the photon and is decreed to vanish. If the photons are virtual, however, as in the electromagnetic interaction between a nucleus and an orbiting electron, or indeed for any externally applied field, the creation and annihilation of a virtual electron-positron pair from time to time causes observable effects. The first effect is a reduction in the observed charge of the nucleus from its value in the absence of interaction. This renormalization of the bare charge can be understood in simple electrostatic terms. The electron of the pair is attracted and the positron repelled by the positive charge of the nucleus. This vacuum polarization effect causes the nuclear charge to be screened and to appear less in magnitude than before. Since charged particles are always surrounded by this cloud of virtual electron-positron pairs, their *observed* charges must be interpreted as

* H. Euler and B. Kockel, *Naturwiss.* **23**, 246 (1935).

their renormalized charges. Beyond the unobservable renormalization of charge, the vacuum polarization induces a charge density within distances of the order of $\hbar/2mc$ or less that causes the electrostatic potential energy between two charges to be greater in magnitude than the Coulomb potential energy. This causes a very small shift in atomic energy levels in the direction of increased binding. The lowest order added potential is proportional to αq_{ext} , where $\alpha = e^2/\hbar c = 1/137$ and q_{ext} is the charge producing the external field. It is thus *linear in the external field* and produces a small linear modification of the Maxwell equations. It is nonlinear in the sense that the strength of the effect depends on the fine structure constant times the external field and so involves the third power of charge in the added potential. Higher order effects, such as Fig. I.3 with three of the photons corresponding to the third power of the external field, give totally nonlinear vacuum polarization effects.

In *electronic* atoms the vacuum polarization effects are a small part of the total radiative correction, but are still observable. In *mu-mesic* atoms, the effects are relatively larger because the atomic orbits are mainly inside the region where the potential is modified. Then vacuum polarization effects are important in their own right.

The final conclusion about linear superposition of fields in vacuum is that in the classical domain of sizes and attainable field strengths there is abundant evidence for the validity of linear superposition and no evidence against it. In the atomic and subatomic domain there are small quantum-mechanical nonlinear effects whose origins are in the coupling between charged particles and the electromagnetic field. They modify the interactions between charged particles and cause interactions between electromagnetic fields even if physical particles are absent.

I.4 The Maxwell Equations in Macroscopic Media

So far we have considered electromagnetic fields and sources in vacuum. The Maxwell equations (I.1) for the electric and magnetic fields \mathbf{E} and \mathbf{B} can be thought of as equations giving the fields everywhere in space, provided all the sources ρ and \mathbf{J} are specified. For a small number of definite sources, determination of the fields is a tractable problem, but for macroscopic aggregates of matter the solution of the equations is almost impossible. There are two aspects here. One is that the number of individual sources, the charged particles in every atom and nucleus, is prohibitively large. The other aspect is that for macroscopic observations the detailed behavior of the fields, with their drastic variations in space over atomic distances, is not relevant. What is relevant is the average of a field or a source over a volume large compared to the volume occupied by a single atom or molecule. We call such averaged quantities the *macroscopic* fields and macroscopic sources. It is shown in detail in Section 6.7 that the *macroscopic*

Maxwell equations are

$$\left. \begin{aligned} \nabla \cdot \mathbf{D} &= 4\pi\rho \\ \nabla \times \mathbf{H} - \frac{1}{c} \frac{\partial \mathbf{D}}{\partial t} &= \frac{4\pi}{c} \mathbf{J} \\ \nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} &= 0 \\ \nabla \cdot \mathbf{B} &= 0 \end{aligned} \right\} \quad (\text{I.6})$$

where \mathbf{E} and \mathbf{B} are the averaged \mathbf{E} and \mathbf{B} of the microscopic or vacuum Maxwell equations (I.1). The two new field quantities \mathbf{D} and \mathbf{H} , usually called the electric displacement and magnetic field (\mathbf{B} is then called the magnetic induction), have components given by

$$\begin{aligned} D_\alpha &= E_\alpha + 4\pi \left(P_\alpha - \sum_\beta \frac{\partial Q'_{\alpha\beta}}{\partial x_\beta} + \dots \right) \\ H_\alpha &= B_\alpha - 4\pi (M_\alpha + \dots) \end{aligned} \quad (\text{I.7})$$

The quantities \mathbf{P} , \mathbf{M} , $Q'_{\alpha\beta}$, and similar higher order objects, represent the macroscopically averaged electric dipole, magnetic dipole, and electric quadrupole, and higher moment densities of the material medium in the presence of applied fields. Similarly, the charge and current densities ρ and \mathbf{J} are macroscopic averages of the “free” charge and current densities in the medium. The bound charges and currents appear in the equations via \mathbf{P} , \mathbf{M} , and $Q'_{\alpha\beta}$.

The macroscopic Maxwell equations (I.6) are a set of eight equations involving the components of the four fields \mathbf{E} , \mathbf{B} , \mathbf{D} , and \mathbf{H} . The four homogeneous equations can be solved formally by expressing \mathbf{E} and \mathbf{B} in terms of the scalar potential Φ and the vector potential \mathbf{A} , but the inhomogeneous equations cannot be solved until the derived fields \mathbf{D} and \mathbf{H} are known in terms of \mathbf{E} and \mathbf{B} . These connections, which are implicit in (I.7), are known as *constitutive relations*,

$$\begin{aligned} \mathbf{D} &= \mathbf{D}[\mathbf{E}, \mathbf{B}] \\ \mathbf{H} &= \mathbf{H}[\mathbf{E}, \mathbf{B}] \end{aligned} \quad (\text{I.8})$$

In addition, for conducting media there is the generalized Ohm’s law,

$$\mathbf{J} = \mathbf{J}[\mathbf{E}, \mathbf{B}] \quad (\text{I.8}')$$

The square brackets are intended to signify that the connections are not necessarily simple and may depend on past history (hysteresis), may be nonlinear, etc.

In most materials the electric quadrupole and higher terms in (I.7) are completely negligible. Only the *electric and magnetic polarizations* \mathbf{P} and \mathbf{M} are significant. This does not mean, however, that the constitutive relations are then simple. There is a tremendous diversity in the electric and magnetic properties of

matter, especially in crystalline solids, with ferroelectric and ferromagnetic materials having nonzero \mathbf{P} or \mathbf{M} in the absence of applied fields, as well as more ordinary dielectric, diamagnetic, and paramagnetic substances. The study of these properties is one of the provinces of solid-state physics. In this book we touch only very briefly and superficially on some more elementary aspects. Solid-state books such as *Kittel* should be consulted for a more systematic and extensive treatment of the electromagnetic properties of bulk matter.

In substances other than ferroelectrics or ferromagnets, for weak enough fields the presence of an applied electric or magnetic field induces an electric or magnetic polarization proportional to the magnitude of the applied field. We then say that the response of the medium is linear and write the Cartesian components of \mathbf{D} and \mathbf{H} in the form,*

$$\left. \begin{aligned} D_\alpha &= \sum_\beta \epsilon_{\alpha\beta} E_\beta \\ H_\alpha &= \sum_\beta \mu'_{\alpha\beta} B_\beta \end{aligned} \right\} \quad (1.9)$$

The tensors $\epsilon_{\alpha\beta}$ and $\mu'_{\alpha\beta}$ are called the electric permittivity or dielectric tensor and the inverse magnetic permeability tensor. They summarize the linear response of the medium and are dependent on the molecular and perhaps crystalline structure of the material, as well as bulk properties like density and temperature. For simple materials the linear response is often isotropic in space. Then $\epsilon_{\alpha\beta}$ and $\mu'_{\alpha\beta}$ are diagonal with all three elements equal, and $\mathbf{D} = \epsilon \mathbf{E}$, $\mathbf{H} = \mu' \mathbf{B}$.

To be generally correct Eqs. (1.9) should be understood as holding for the Fourier transforms in space and time of the field quantities. This is because the basic linear connection between \mathbf{D} and \mathbf{E} (or \mathbf{H} and \mathbf{B}) can be nonlocal. Thus

$$D_\alpha(\mathbf{x}, t) = \sum_\beta \int d^3x' \int dt' \epsilon_{\alpha\beta}(\mathbf{x}', t') E_\beta(\mathbf{x} - \mathbf{x}', t - t') \quad (1.10)$$

where $\epsilon_{\alpha\beta}(\mathbf{x}', t')$ may be localized around $\mathbf{x}' = 0$, $t' = 0$, but is nonvanishing for some range away from the origin. If we introduce the Fourier transforms $D_\alpha(\mathbf{k}, \omega)$, $E_\beta(\mathbf{k}, \omega)$, and $\epsilon_{\alpha\beta}(\mathbf{k}, \omega)$ through

$$f(\mathbf{k}, \omega) = \int d^3x \int dt f(\mathbf{x}, t) e^{-i\mathbf{k} \cdot \mathbf{x} + i\omega t}$$

Eq. (1.9) can be written in terms of the Fourier transforms as

$$D_\alpha(\mathbf{k}, \omega) = \sum_\beta \epsilon_{\alpha\beta}(\mathbf{k}, \omega) E_\beta(\mathbf{k}, \omega) \quad (1.11)$$

A similar equation can be written $H_\alpha(\mathbf{k}, \omega)$ in terms of $B_\beta(\mathbf{k}, \omega)$. The permeability tensors are therefore functions of frequency and wave vector in general. For visible light or

* Precedent would require writing $B_\alpha = \sum_\beta \mu_{\alpha\beta} H_\beta$, but this reverses the natural roles of \mathbf{B} as the basic magnetic field and \mathbf{H} as the derived quantity. In Chapter 5 we revert to the traditional usage.

electromagnetic radiation of longer wavelength it is often permissible to neglect the nonlocality in space. Then $\epsilon_{\alpha\beta}$ and $\mu'_{\alpha\beta}$ are functions only of frequency. This is the situation discussed in Chapter 7 where a simplified treatment of the high frequency properties of matter is given and the consequences of causality explored. For conductors and superconductors long-range effects can be important. For example, when the electronic collisional mean free path in a conductor becomes large compared to the skin depth, a spatially local form of Ohm's law is no longer adequate. Then the dependence on wave vector also enters. In the understanding of a number of properties of solids the concept of a dielectric constant as a function of wave vector and frequency is fruitful. Some exemplary references are given in the suggested reading at the end of this introduction.

For orientation we mention that at low frequencies ($\nu \leq 10^6$ Hz) where all charges, regardless of their inertia, respond to applied fields, solids have dielectric constants typically in the range of $\epsilon_{\alpha\alpha} \sim 2-20$, with larger values not uncommon. Systems with permanent molecular dipole moments can have much larger and temperature sensitive dielectric constants. Distilled water, for example, has a static dielectric constant of $\epsilon = 88$ at 0°C and $\epsilon = 56$ at 100°C . At optical frequencies only the electrons can respond significantly. The dielectric constants are in the range, $\epsilon_{\alpha\alpha} \sim 1.7-10$, with $\epsilon_{\alpha\alpha} \approx 2-3$ for most solids. Water has $\epsilon = 1.77-1.80$ over the visible range, essentially independent of temperature from 0 to 100°C .

The type of response of materials to an applied magnetic field depends on the properties of the individual atoms or molecules and also on their interactions. *Diamagnetic* substances consist of atoms or molecules with no net angular momentum. The response to an applied magnetic field is the creation of circulating atomic currents that produce a very small bulk magnetization opposing the applied field. With the definition of $\mu'_{\alpha\beta}$ in (I.9) and the form of (I.7), this means $\mu'_{\alpha\alpha} > 1$. Bismuth, the most diamagnetic substance known, has $(\mu'_{\alpha\alpha} - 1) \approx 1.8 \times 10^{-4}$. Thus diamagnetism is a very small effect. If the basic atomic unit of the material has a net angular momentum from unpaired electrons, the substance is *paramagnetic*. The magnetic moment of the odd electron is aligned parallel to the applied field. Hence $\mu'_{\alpha\alpha} < 1$. Typical values are in the range $(1 - \mu'_{\alpha\alpha}) \approx 10^{-2} - 10^{-5}$ at room temperature, but decreasing at higher temperatures because of the randomizing effect of thermal excitations.

Ferromagnetic materials are paramagnetic but, because of interactions between atoms, show drastically different behavior. Below the Curie temperature (1040°K for Fe, 630°K for Ni), ferromagnetic substances show spontaneous magnetization, that is, all the magnetic moments in a microscopically large region called a domain are aligned. The application of an external field tends to cause the domains to change and the moments in different domains to line up together, leading to the saturation of the bulk magnetization. Removal of the field leaves a considerable fraction of the moments still aligned, giving a permanent magnetization that can be as large as $B_r = 4\pi M_r \approx 10^4$ gauss.

For data on the dielectric and magnetic properties of materials the reader can

consult some of the basic physics handbooks* from which he or she will be led to more specific and detailed compilations.

Materials that show a linear response to weak fields eventually show *nonlinear behavior* at high enough field strengths as the electronic or ionic oscillators are driven to large amplitudes. The linear relations (I.9) are modified to, for example,

$$D_{\alpha} = \sum_{\beta} \epsilon_{\alpha\beta}^{(1)} E_{\beta} + \sum_{\beta, \gamma} \epsilon_{\alpha\beta\gamma}^{(2)} E_{\beta} E_{\gamma} + \cdots \quad (\text{I.12})$$

For static fields the consequences are not particularly dramatic, but for time-varying fields it is another matter. A large amplitude wave of two frequencies ω_1 and ω_2 generates waves in the medium with frequencies 0, $2\omega_1$, $2\omega_2$, $\omega_1 + \omega_2$, $\omega_1 - \omega_2$, as well as the original ω_1 and ω_2 . From cubic and higher nonlinear terms an even richer spectrum of frequencies can be generated. With the development of lasers, nonlinear behavior of this sort has become a research area of its own, called *nonlinear optics*, and also a laboratory tool. At present, lasers are capable of generating light pulses with peak electric fields approaching 10^{10} or even 10^{11} volts/cm. The static electric field experienced by the electron in its orbit in a hydrogen atom is $e/a_0^2 \approx 5 \times 10^9$ volts/cm. Such laser fields are thus seen to be capable of driving atomic oscillators well into their nonlinear regime, capable indeed of destroying the sample under study! References to some of the literature of this specialized field are given in the suggested reading at the end of this introduction. The reader of this book will have to be content with basically linear phenomena.

I.5 Boundary Conditions at Interfaces between Different Media

The Maxwell equations (I.6) are differential equations applying locally at each point in space-time (\mathbf{x}, t) . By means of the divergence theorem and Stokes's theorem, they can be cast in integral form. Let V be a finite volume in space, S the closed surface (or surfaces) bounding it, da an element of area on the surface, and \mathbf{n} a unit normal to the surface at da pointing outward from the enclosed volume. Then the divergence theorem applied to the first and last equations of (I.6) yields the integral statements

$$\oint_S \mathbf{D} \cdot \mathbf{n} \, da = 4\pi \int_V \rho \, d^3x \quad (\text{I.13})$$

$$\oint_S \mathbf{B} \cdot \mathbf{n} \, da = 0 \quad (\text{I.14})$$

* *Handbook of Chemistry and Physics*, ed. R. C. Weast, Chemical Rubber Publishing House, Cleveland, Ohio.

American Institute of Physics Handbook, ed. D. E. Gray, McGraw Hill, New York, 3rd edition (1972), Sects. 5.d and 5.f.

The first relation is just Gauss's law that the total flux of \mathbf{D} out through the surface is proportional to the charge contained inside. The second is the magnetic analog, with no net flux of \mathbf{B} through a closed surface because of the nonexistence of magnetic charges.

Similarly, let C be a closed contour in space, S' an open surface spanning the contour, $d\mathbf{l}$ a line element on the contour, da an element of area on S' , and \mathbf{n}' a unit normal at da pointing in the direction given by the right-hand rule from the sense of integration around the contour. Then applying Stokes's theorem to the middle two equations in (I.6) gives the integral statements

$$\oint_C \mathbf{H} \cdot d\mathbf{l} = \int_{S'} \left[\frac{4\pi}{c} \mathbf{J} + \frac{1}{c} \frac{\partial \mathbf{D}}{\partial t} \right] \cdot \mathbf{n}' da \quad (\text{I.15})$$

$$\oint_C \mathbf{E} \cdot d\mathbf{l} = -\frac{1}{c} \int_{S'} \frac{\partial \mathbf{B}}{\partial t} \cdot \mathbf{n}' da \quad (\text{I.16})$$

Equation (I.15) is the Ampère–Maxwell law of magnetic fields and (I.16) is Faraday's law of electromagnetic induction.

These familiar integral equivalents of the Maxwell equations can be used directly to deduce the relationship of various normal and tangential components of the fields on either side of a surface between different media, perhaps with a surface charge or current density at the interface. An appropriate geometrical arrangement is shown in Fig. I.4. An infinitesimal Gaussian pillbox straddles the boundary surface between two media with different electromagnetic properties.

Fig. I.4 Schematic diagram of boundary surface (heavy line) between different media. The boundary region is assumed to carry idealized surface charge and current densities σ and \mathbf{K} . The volume V is a small pillbox, half in one medium and half in the other, with the normal \mathbf{n} to its top pointing from medium 1 into medium 2. The rectangular contour C is partly in one medium and partly in the other and is oriented with its plane perpendicular to the surface so that its normal \mathbf{t} is tangent to the surface.

Similarly, the infinitesimal contour C has its long arms on either side of the boundary and is oriented so that the normal to its spanning surface is tangent to the interface. We first apply the integral statements (I.13) and (I.14) to the volume of the pillbox. In the limit of a very shallow pillbox, the side surface does not contribute to the integrals on the left in (I.13) and (I.14). Only the top and bottom contribute. If the top and bottom are parallel, tangent to the surface, and of area Δa , then the left-hand integral in (I.13) is

$$\oint_S \mathbf{D} \cdot \mathbf{n} da = (\mathbf{D}_2 - \mathbf{D}_1) \cdot \mathbf{n} \Delta a$$

and similarly for (I.14). If the charge density ρ is singular at the interface so as to produce an idealized surface charge density σ , then the integral on the right in (I.13) is

$$4\pi \int_V \rho d^3x = 4\pi\sigma \Delta a$$

Thus the *normal components* of \mathbf{D} and \mathbf{B} on either side of the boundary surface are related according to

$$(\mathbf{D}_2 - \mathbf{D}_1) \cdot \mathbf{n} = 4\pi\sigma \quad (\text{I.17})$$

$$(\mathbf{B}_2 - \mathbf{B}_1) \cdot \mathbf{n} = 0 \quad (\text{I.18})$$

In words, we say that the normal component of \mathbf{B} is continuous and the discontinuity of the normal component of \mathbf{D} at any point is equal to 4π times the surface charge density at that point.

In an analogous manner the infinitesimal Stokesian loop can be used to determine the discontinuities of the tangential components of \mathbf{E} and \mathbf{H} . If the short arms of the contour C in Fig. I.4 are of negligible length and the long arms are each parallel to the surface and of length Δl , then the left-hand integral of (I.16) is

$$\oint_C \mathbf{E} \cdot d\mathbf{l} = (\mathbf{t} \times \mathbf{n}) \cdot (\mathbf{E}_2 - \mathbf{E}_1) \Delta l$$

and similarly for the left-hand side of (I.15). The right-hand side of (I.16) vanishes because $\partial \mathbf{B} / \partial t$ is finite at the surface and the area of the loop is zero as the length of the short sides goes to zero. The right-hand side of (I.15) does not vanish, however, if there is an idealized surface current density \mathbf{K} flowing exactly on the boundary surface. In such circumstances the integral on the right of (I.15) is

$$\int_{S'} \left[\frac{4\pi}{c} \mathbf{J} + \frac{1}{c} \frac{\partial \mathbf{D}}{\partial t} \right] \cdot \mathbf{t} da = \frac{4\pi}{c} \mathbf{K} \cdot \mathbf{t} \Delta l$$

The second term in the integral vanishes by the same argument that was just given. The *tangential components* of \mathbf{E} and \mathbf{H} on either side of the boundary are

Fig. I.5 Moving boundary between two media. The pillbox and loop are as in Fig. I.4 and are stationary in the laboratory. The dashed lines show the interface a moment before and after the instant shown.

therefore related by

$$\mathbf{n} \times (\mathbf{E}_2 - \mathbf{E}_1) = 0 \quad (\text{I.19})$$

$$\mathbf{n} \times (\mathbf{H}_2 - \mathbf{H}_1) = \frac{4\pi}{c} \mathbf{K} \quad (\text{I.20})$$

In Eq. (I.20) it is understood that the surface current \mathbf{K} has only components parallel to the surface at every point. The tangential component of \mathbf{E} across an interface is continuous, while the tangential component of \mathbf{H} is discontinuous by an amount whose magnitude is equal to $4\pi/c$ times the magnitude of the surface current density and whose direction is parallel to $\mathbf{K} \times \mathbf{n}$.

The discontinuity equations (I.17)–(I.20) are useful in solving the Maxwell equations in different regions and then connecting the solutions to obtain the fields throughout all space.

The discontinuity formulas presented above hold in the common circumstance that the interface between the two media is fixed as a function of time. In some applications it may be useful to have the discontinuities for a moving boundary.* The results for a boundary surface moving with velocity $\mathbf{v} = c\boldsymbol{\beta}$ can be obtained in essentially the same way as previously, provided a little care is taken. The moving boundary surface between the two media is shown schematically in Fig. I.5, along with the infinitesimal Gaussian pillbox and Stokesian loop. The pillbox and loop are fixed in the laboratory. The boundary surface sweeps past them with velocity \mathbf{v} . If we now consider the derivation of the discontinuity formulas (I.17) and (I.18) for \mathbf{D} and \mathbf{B} , we see that the same arguments starting from

* P. D. Noerdlinger, *Am. J. Physics* **39**, 191 (1971).

(I.13) and (I.14) are valid without change, provided σ is interpreted as the surface charge density on the moving surface *as observed in the laboratory*. Therefore the discontinuity formulas for \mathbf{D} and \mathbf{B} , (I.17) and (I.18), hold without modification for a moving interface.

The discontinuity formulas (I.19) and (I.20) for \mathbf{E} and \mathbf{H} are modified, however. This comes about because the time derivative terms on the right-hand sides of (I.15) and (I.16) no longer vanish. The sweeping of the interface past the stationary loop C gives a contribution. To determine its value, consider the surface integral of the time derivative of \mathbf{D}/c over the open surface identical in shape to C , but moving with the interface at velocity \mathbf{v} and instantaneously coincident with C in Fig. I.5. The integral is

$$I = \int \frac{1}{c} \frac{d\mathbf{D}}{dt} (\mathbf{x}(t), t) \cdot \mathbf{t} da$$

We have indicated the implicit time dependence of the coordinate \mathbf{x} to emphasize that the integration is over a moving surface. In the limit that the area of the open surface vanishes as the short arms of the rectangular loop C become vanishingly small, the integral I vanishes. (From the viewpoint of special relativity, an observer in an inertial frame moving with velocity \mathbf{v} sees the interface at rest, and observes Lorentz-transformed fields that are not singular at the interface.) The integral I can, however, be related to the integral appearing in (I.15) through the convective derivative expansion:

$$\begin{aligned} 0 = I &= \int \frac{1}{c} \frac{d\mathbf{D}}{dt} (\mathbf{x}(t), t) \cdot \mathbf{t} da \\ &= \int \frac{1}{c} \frac{\partial \mathbf{D}}{\partial t} \cdot \mathbf{t} da + \int [(\boldsymbol{\beta} \cdot \boldsymbol{\nabla}) \mathbf{D}] \cdot \mathbf{t} da \end{aligned}$$

Using a vector identity the second term can be transformed and the required integral becomes

$$\int \frac{1}{c} \frac{\partial \mathbf{D}}{\partial t} \cdot \mathbf{t} da = \int [\boldsymbol{\nabla} \times (\boldsymbol{\beta} \times \mathbf{D}) - \boldsymbol{\beta} \boldsymbol{\nabla} \cdot \mathbf{D}] \cdot \mathbf{t} da$$

The first term on the right can be transformed by Stokes's theorem into a loop integral and the second can be expressed in terms of the charge density ρ . We therefore have as the application of (I.15) to the loop C in Fig. I.5 the expression

$$\oint_C [\mathbf{H} - \boldsymbol{\beta} \times \mathbf{D}] \cdot d\mathbf{l} = \frac{4\pi}{c} \int [\mathbf{J} - \rho \mathbf{v}] \cdot \mathbf{t} da$$

By the same steps as above (I.19) and (I.20), we obtain from this relation the discontinuity formula,

$$\mathbf{t} \cdot \{\mathbf{n} \times [\mathbf{H}_2 - \mathbf{H}_1 - \boldsymbol{\beta} \times (\mathbf{D}_2 - \mathbf{D}_1)]\} = \frac{4\pi}{c} (\mathbf{K} - \sigma \mathbf{v}) \cdot \mathbf{t}$$

where all quantities are evaluated in the laboratory frame. Some vector manipulation and use of (I.17) leads to

$$\mathbf{t} \cdot [\mathbf{n} \times (\mathbf{H}_2 - \mathbf{H}_1) + \mathbf{n} \cdot \boldsymbol{\beta} (\mathbf{D}_2 - \mathbf{D}_1)] = \frac{4\pi}{c} \mathbf{K} \cdot \mathbf{t} \quad (\text{I.21})$$

A completely similar derivation from (I.16) yields

$$\mathbf{t} \cdot [\mathbf{n} \times (\mathbf{E}_2 - \mathbf{E}_1) - \mathbf{n} \cdot \boldsymbol{\beta} (\mathbf{B}_2 - \mathbf{B}_1)] = 0 \quad (\text{I.22})$$

as the discontinuity formula for the tangential components of \mathbf{E} (and \mathbf{B}). Equations (I.21) and (I.22) represent the generalizations of (I.19) and (I.20) to the circumstance of a moving interface between two media.

In the simplified situation where $\mathbf{D} \approx \mathbf{E}$ and $\mathbf{H} \approx \mathbf{B}$ in both media (or these hold in one medium and the other medium is an excellent conductor with all fields essentially zero inside), the relation involving the surface current simplifies considerably. Equation (I.22) can be written (without approximation) as

$$(\mathbf{E}_2 - \mathbf{E}_1)_{\text{tan}} = -(\mathbf{n} \cdot \boldsymbol{\beta}) \mathbf{n} \times (\mathbf{B}_2 - \mathbf{B}_1) \quad (\text{I.23})$$

Then with $\mathbf{H} \rightarrow \mathbf{B}$ and $\mathbf{D} \rightarrow \mathbf{E}$ in (I.21), Eq. (I.23) can be substituted to give

$$[1 - (\mathbf{n} \cdot \boldsymbol{\beta})^2] \mathbf{n} \times (\mathbf{B}_2 - \mathbf{B}_1) = \frac{4\pi}{c} \mathbf{K} \quad (\text{I.24})$$

The motion of the interface between the media introduces only an overall multiplicative factor into (I.20), a correction of relative order v^2/c^2 .

I.6 Some Remarks on Idealizations in Electromagnetism

In the previous section we made use of the idea of surface distributions of charge and current. These are obviously mathematical idealizations that do not exist in the physical world. There are other abstractions that occur throughout electromagnetism. In electrostatics, for example, we speak of holding objects at a fixed potential with respect to some zero of potential usually called "ground." The relation of such idealizations to the real world is perhaps worthy of a little discussion, even though to the experienced hand most will seem obvious.

First we consider the question of maintaining some conducting object at a fixed electrostatic potential with respect to some reference value. Implicit is the idea that the means does not significantly disturb the desired configuration of charges and fields. To maintain an object at fixed potential it is necessary, at least from time to time, to have a conducting path or its equivalent from the object to a source of charge far away ("at infinity") so that as other charged or uncharged objects are brought in the vicinity charge can flow to or from the object, always maintaining its potential at the desired value. Although more sophisticated means are possible, metallic wires are commonly used to make the conducting path. Intuitively we expect small wires to be less perturbing than large ones. The reason is as follows. "Since the quantity of electricity on any given portion of a wire at a given potential diminishes indefinitely when the diameter of the wire is indefinitely diminished, the distribution of electricity on bodies of considerable dimensions will not be sensibly affected by the introduction of very fine metallic wires into the field, such as are used to form electrical connexions between these bodies and the earth, an electrical machine, or an electrometer."* The electric field in the immediate neighborhood of the thin wire is very large, of course. However, at distances away of the order of the size of the "bodies of considerable dimensions" the effects can be made small. An important historical

* J. C. Maxwell, *A Treatise on Electricity and Magnetism*, Dover, New York, 1954 reprint of the 3rd edition (1891), Vol. 1, p. 96.

illustration of Maxwell's words is given by the work of Henry Cavendish 200 years ago. By experiments done in a converted stable of his father's house, using Leyden jars as his sources of charge, thin wires as conductors, and suspending the objects in the room, Cavendish measured the amounts of charge on cylinders, discs, etc., held at fixed potential and compared them to the charge on a sphere (the same sphere shown in Fig. I.1) at the same potential. His values of capacitance, so measured, are accurate to a few per cent. For example, he found the ratio of the capacitance of a sphere to that of a thin circular disc of the same radius was 1.57. The theoretical value is $\pi/2$.

There is a practical limit to the use of finer and finer wires. The charge per unit length decreases only logarithmically (as the reciprocal of $\ln(d/a)$, where a is the mean radius of the wire and d is a typical distance of the wire from some conducting surface). To minimize the perturbation of the system below some level, it is necessary to resort to other means to maintain potentials, comparison methods using beams of charged particles intermittently, for example.

When a conducting object is said to be *grounded*, it is assumed to be connected by a very fine conducting filament to a remote reservoir of charge that serves as the common zero of potential. Objects held at fixed potentials are similarly connected to one side of a voltage source, such as a battery, the other side of which is connected to the common "ground." Then, when initially electrified objects are moved relative to one another in such a way that their distributions of electricity are altered, but their potentials remain fixed, the appropriate amounts of charge flow from or to the remote reservoir, assumed to have an inexhaustible supply. The idea of grounding something is a well-defined concept in electrostatics where time is not a factor, but for oscillating fields the finite speed of propagation blurs the concept. In other words, stray inductive and capacitive effects can enter significantly. Great care is then necessary to ensure a "good ground."

Another idealization in macroscopic electromagnetism is the idea of a surface charge density or a surface current density. The physical reality is that the charge or current is confined to the immediate neighborhood of the surface. If this region has thickness small compared to the length scale of interest, we may approximate the reality by the idealization of a region of infinitesimal thickness and speak of a surface distribution. Two different limits need to be distinguished. One is the limit in which the "surface" distribution is confined to a region near the surface that is *macroscopically small, but microscopically large*. An example is the penetration of time-varying fields into a very good, but not perfect, conductor, described in Section 8.1. It is found that the fields are confined to a thickness δ , called the skin depth, and that for high enough frequencies and good enough conductivities δ can be macroscopically very small. It is then appropriate to integrate the current density \mathbf{J} over the direction perpendicular to the surface to obtain an effective surface current density \mathbf{K}_{eff} .

The other limit is *truly microscopic* and is set by quantum-mechanical effects in

Fig. 1.6 Distribution of excess charge at the surface of a conductor and of the normal component of the electric field. The ions of the solid are confined to $x < 0$ and are approximated by a constant continuous charge distribution through which the electrons move. The bulk of the excess charge is confined to within ± 2 angstroms of the “surface.”

the atomic structure of materials. Consider, for instance, the distribution of excess charge of a conducting body in electrostatics. It is well known that this charge lies entirely on the surface of a conductor. We then speak of a *surface* charge density σ . There is no electric field inside the conductor, but there is, in accord with (I.17), a normal component of electric field just outside the surface. At the microscopic level the charge is not exactly at the surface and the field does not change discontinuously. The most elementary considerations would indicate that the transition region is a few atomic diameters in extent. The ions in a metal can be thought of as relatively immobile and localized to 1 angstrom or better; the lighter electrons are less constrained. The results of model calculations* are shown in Fig. 1.6. They come from a solution of the quantum-mechanical many-electron problem in which the ions of the conductor are approximated by a continuous constant charge density for $x < 0$. The electron density ($r_s = 5$) is roughly appropriate to copper and the heavier alkali metals. The excess

electronic charge is seen to be confined to a region within ± 2 angstroms of the "surface" of the ionic distribution. The electric field rises smoothly over this region to its value of $4\pi\sigma$ "outside" the conductor. For macroscopic situations where 10^{-7} cm is a negligible distance, we can idealize the charge density and electric field behavior as $\rho(x) = \sigma\delta(x)$ and $E_n(x) = 4\pi\sigma\theta(x)$, corresponding to a truly surface density and a step-function jump of the field.

We see that the theoretical treatment of classical electromagnetism involves several idealizations, some of them technical and some physical. The subject of electrostatics, discussed in the first chapters of the book, developed as an experimental science of *macroscopic* electrical phenomena, as did virtually all other aspects of electromagnetism. The extension of these macroscopic laws, even for charges and currents in vacuum, to the *microscopic* domain was for the most part an unjustified extrapolation. Earlier in this introduction we have discussed some of the limits to this extrapolation. The point to be made here is the following. With hindsight we know that many aspects of the laws of classical electromagnetism apply well into the atomic domain provided the sources are treated quantum mechanically, that the averaging of electromagnetic quantities over volumes containing large numbers of molecules so smooths the rapid fluctuations that static applied fields induce static average responses in matter, that excess charge is *on* the surface of a conductor in a macroscopic sense. Thus Coulomb's and Ampère's macroscopic observations and our mathematical abstractions from them have a wider applicability than might be supposed by a supercautious physicist. The absence for air of significant electric or magnetic susceptibility certainly simplified matters!

REFERENCES AND SUGGESTED READING

The history of electricity and magnetism is in large measure the history of science itself.

1

Introduction to Electrostatics

We begin our discussion of electrodynamics with the subject of *electrostatics*—phenomena involving time-independent distributions of charge and fields. For most readers this material is in the nature of a review. In this chapter especially we do not elaborate significantly. We introduce concepts and definitions that are important for later discussion and present some essential mathematical apparatus. In subsequent chapters the mathematical techniques are developed and applied.

One point of physics should be mentioned. Historically, electrostatics developed as a science of *macroscopic* phenomena. As indicated at the end of the Introduction, such idealizations as point charges or electric fields at a point must be viewed as mathematical constructs that permit a description of the phenomena at the macroscopic level, but that may fail to have meaning microscopically.

1.1 Coulomb's Law

All of electrostatics stems from the quantitative statement of Coulomb's law concerning the force acting between charged bodies at rest with respect to each other. Coulomb, in an impressive series of experiments, showed experimentally that the force between two small charged bodies separated in air a distance large compared to their dimensions

- (1) varied directly as the magnitude of each charge,
- (2) varied inversely as the square of the distance between them,
- (3) was directed along the line joining the charges,
- (4) was attractive if the bodies were oppositely charged and repulsive if the bodies had the same type of charge.

Furthermore it was shown experimentally that the total force produced on one small charged body by a number of the other small charged bodies placed

around it was the *vector* sum of the individual two-body forces of Coulomb. Strictly speaking, Coulomb's conclusions apply to charges in vacuum or in media of negligible susceptibility. We defer consideration of charges in dielectrics to Chapter 4.

1.2 Electric Field

Although the thing that eventually gets measured is a force, it is useful to introduce a concept one step removed from the forces, the concept of an electric field due to some array of charged bodies. At the moment, the electric field can be defined as the force per unit charge acting at a given point. It is a vector function of position, denoted by \mathbf{E} . One must be careful in its definition, however. It is not necessarily the force that one would observe by placing one unit of charge on a pith ball and placing it in position. The reason is that one unit of charge may be so large that its presence alters appreciably the field configuration of the array. Consequently one must use a limiting process whereby the ratio of the force on the small test body to the charge on it is measured for smaller and smaller amounts of charge.* Experimentally, this ratio and the direction of the force will become constant as the amount of test charge is made smaller and smaller. These limiting values of magnitude and direction define the magnitude and direction of the electric field \mathbf{E} at the point in question. In symbols we may write

$$\mathbf{F} = q\mathbf{E} \quad (1.1)$$

where \mathbf{F} is the force, \mathbf{E} the electric field, and q the charge. In this equation it is assumed that the charge q is located at a point, and the force and the electric field are evaluated at that point.

Coulomb's law can be written down similarly. If \mathbf{F} is the force on a point charge q_1 , located at \mathbf{x}_1 , due to another point charge q_2 , located at \mathbf{x}_2 , then Coulomb's law is

$$\mathbf{F} = kq_1q_2 \frac{(\mathbf{x}_1 - \mathbf{x}_2)}{|\mathbf{x}_1 - \mathbf{x}_2|^3} \quad (1.2)$$

Note that q_1 and q_2 are algebraic quantities which can be positive or negative. The constant of proportionality k depends on the system of units used.

The electric field at the point \mathbf{x} due to a point charge q_1 at the point \mathbf{x}_1 can be obtained directly:

$$\mathbf{E}(\mathbf{x}) = kq_1 \frac{(\mathbf{x} - \mathbf{x}_1)}{|\mathbf{x} - \mathbf{x}_1|^3} \quad (1.3)$$

* The discreteness of electric charge (see Section I.1) means that this mathematical limit is impossible to realize physically. This is an example of a mathematical idealization in macroscopic electrostatics.

Fig. 1.1

as indicated in Fig. 1.1. The constant k is determined by the unit of charge chosen. In electrostatic units (esu), unit charge is chosen as that charge which exerts a force of one dyne on an equal charge located one centimeter away. Thus, with cgs units, $k = 1$ and the unit of charge is called the “stat-coulomb.” In the MKSA system, $k = (4\pi\epsilon_0)^{-1}$, where ϵ_0 ($= 8.854 \times 10^{-12}$ farad/meter) is the permittivity of free space. We will use esu.*

The experimentally observed linear superposition of forces due to many charges means that we may write the electric field at \mathbf{x} due to a system of point charges q_i , located at \mathbf{x}_i , $i = 1, 2, \dots, n$, as the vector sum:

$$\mathbf{E}(\mathbf{x}) = \sum_{i=1}^n q_i \frac{(\mathbf{x} - \mathbf{x}_i)}{|\mathbf{x} - \mathbf{x}_i|^3} \quad (1.4)$$

If the charges are so small and so numerous that they can be described by a charge density $\rho(\mathbf{x}')$ [if Δq is the charge in a small volume $\Delta x \Delta y \Delta z$ at the point \mathbf{x}' , then $\Delta q = \rho(\mathbf{x}') \Delta x \Delta y \Delta z$], the sum is replaced by an integral:

$$\mathbf{E}(\mathbf{x}) = \int \rho(\mathbf{x}') \frac{(\mathbf{x} - \mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|^3} d^3 x' \quad (1.5)$$

where $d^3 x' = dx' dy' dz'$ is a three-dimensional volume element at \mathbf{x}' .

At this point it is worth while to introduce the *Dirac delta function*. In one dimension, the delta function, written $\delta(x-a)$, is a mathematically improper function having the properties:

(1) $\delta(x-a) = 0$ for $x \neq a$, and

(2) $\int \delta(x-a) dx = 1$ if the region of integration includes $x = a$, and is zero otherwise.

The delta function can be given, an intuitive, but nonrigorous, meaning as the limit of a peaked curve such as a Gaussian which becomes narrower and narrower, but higher and higher, in such a way that the area under the curve is always constant. L. Schwartz's theory of distributions is a comprehensive rigorous mathematical approach to delta functions and their manipulations.†

From the definitions above it is evident that, for an arbitrary function $f(x)$,

(3) $\int f(x) \delta(x-a) dx = f(a)$.

The integral of $f(x)$ times the derivative of a delta function is simply understood if the delta function is thought of as a well-behaved, but sharply peaked, function. Thus the

* The question of units is discussed in detail in the Appendix.

† A useful, rigorous account of the Dirac delta function is given by *Lighthill*. See also *Dennerly and Krzywicki*, Sect. III.13. (Full references for items cited in the text or footnotes by italicized author only will be found in the Bibliography.)

definition is

$$(4) \int f(x) \delta'(x-a) dx = -f'(a)$$

where a prime denotes differentiation with respect to the argument.

If the delta function has as argument a function $f(x)$ of the independent variable x , it can be transformed according to the rule,

$$(5) \delta(f(x)) = \sum_i \frac{1}{\left| \frac{df}{dx}(x_i) \right|} \delta(x-x_i)$$

where $f(x)$ is assumed to have only simple zeros, located at $x=x_i$.

In more than one dimension, we merely take products of delta functions in each dimension. In three dimensions, for example, with Cartesian coordinates,

$$(6) \delta(\mathbf{x}-\mathbf{X}) = \delta(x_1-X_1) \delta(x_2-X_2) \delta(x_3-X_3)$$

is a function which vanishes everywhere except at $\mathbf{x}=\mathbf{X}$, and is such that

$$(7) \int_{\Delta V} \delta(\mathbf{x}-\mathbf{X}) d^3x = \begin{cases} 1 & \text{if } \Delta V \text{ contains } \mathbf{x}=\mathbf{X} \\ 0 & \text{if } \Delta V \text{ does not contain } \mathbf{x}=\mathbf{X} \end{cases}$$

Note that a delta function has the dimensions of an inverse volume in whatever number of dimensions the space has.

A discrete set of point charges can be described with a charge density by means of delta functions. For example,

$$\rho(\mathbf{x}) = \sum_{i=1}^n q_i \delta(\mathbf{x}-\mathbf{x}_i) \quad (1.6)$$

represents a distribution of n point charges q_i , located at the points \mathbf{x}_i . Substitution of this charge density (1.6) into (1.5) and integration, using the properties of the delta function, yields the discrete sum (1.4).

1.3 Gauss's Law

The integral (1.5) is not the most suitable form for the evaluation of electric fields. There is another integral result, called *Gauss's law*, which is sometimes more useful and which furthermore leads to a differential equation for $\mathbf{E}(\mathbf{x})$. To obtain Gauss's law we first consider a point charge q and a *closed* surface S , as shown in Fig. 1.2. Let r be the distance from the charge to a point on the surface, \mathbf{n} be the outwardly directed unit normal to the surface at that point, da be an element of surface area. If the electric field \mathbf{E} at the point on the surface due to the charge q makes an angle θ with the unit normal, then the normal component of \mathbf{E} times the area element is:

$$\mathbf{E} \cdot \mathbf{n} da = q \frac{\cos \theta}{r^2} da \quad (1.7)$$

Since \mathbf{E} is directed along the line from the surface element to the charge q , $\cos \theta da = r^2 d\Omega$, where $d\Omega$ is the element of solid angle subtended by da at the position of the charge. Therefore

$$\mathbf{E} \cdot \mathbf{n} da = q d\Omega \quad (1.8)$$

Fig. 1.2 Gauss's law. The normal component of electric field is integrated over the closed surface S . If the charge is inside (outside) S , the total solid angle subtended at the charge by the inner side of the surface is 4π (zero).

If we now integrate the normal component of \mathbf{E} over the whole surface, it is easy to see that

$$\oint_S \mathbf{E} \cdot \mathbf{n} \, da = \begin{cases} 4\pi q & \text{if } q \text{ lies inside } S \\ 0 & \text{if } q \text{ lies outside } S \end{cases} \quad (1.9)$$

This result is Gauss's law for a single point charge. For a discrete set of charges, it is immediately apparent that

$$\oint_S \mathbf{E} \cdot \mathbf{n} \, da = 4\pi \sum_i q_i \quad (1.10)$$

where the sum is over only those charges *inside* the surface S . For a continuous charge density $\rho(\mathbf{x})$, Gauss's law becomes:

$$\oint_S \mathbf{E} \cdot \mathbf{n} \, da = 4\pi \int_V \rho(\mathbf{x}) \, d^3x \quad (1.11)$$

where V is the volume enclosed by S .

Equation (1.11) is one of the basic equations of electrostatics. Note that it depends upon

- (1) the inverse square law for the force between charges,
- (2) the central nature of the force,
- (3) the linear superposition of the effects of different charges.

Clearly, then, Gauss's law holds for Newtonian gravitational force fields, with matter density replacing charge density.

It is interesting to note that, even before the experiments of Cavendish and Coulomb, Priestley, taking up an observation of Franklin that charge seemed to reside on the outside, but not the inside, of a metal cup, reasoned by analogy with Newton's law of universal gravitation that the electrostatic force must obey an inverse square law with distance. The present status of the inverse square law is discussed in Section I.2.

1.4 Differential Form of Gauss's Law

Gauss's law can be thought of as being an integral formulation of the law of electrostatics. We can obtain a differential form (i.e., a differential equation) by using the divergence theorem. The *divergence theorem* states that for any well-behaved vector field $\mathbf{A}(\mathbf{x})$ defined within a volume V surrounded by the closed surface S the relation

$$\oint_S \mathbf{A} \cdot \mathbf{n} \, da = \int_V \nabla \cdot \mathbf{A} \, d^3x$$

holds between the volume integral of the divergence of \mathbf{A} and the surface integral of the outwardly directed normal component of \mathbf{A} . The equation in fact can be used as the definition of the divergence (see *Stratton*, p. 4).

To apply the divergence theorem we consider the integral relation expressed in Gauss's theorem:

$$\oint_S \mathbf{E} \cdot \mathbf{n} \, da = 4\pi \int_V \rho(\mathbf{x}) \, d^3x$$

Now the divergence theorem allows us to write this as:

$$\int_V (\nabla \cdot \mathbf{E} - 4\pi\rho) \, d^3x = 0 \quad (1.12)$$

for an arbitrary volume V . We can, in the usual way, put the integrand equal to zero to obtain

$$\nabla \cdot \mathbf{E} = 4\pi\rho \quad (1.13)$$

which is the differential form of Gauss's law of electrostatics. This equation can itself be used to solve problems in electrostatics. However, it is often simpler to deal with scalar rather than vector functions of position, and then to derive the vector quantities at the end if necessary (see below).

1.5 Another Equation of Electrostatics and the Scalar Potential

The single equation (1.13) is not enough to specify completely the three components of the electric field $\mathbf{E}(\mathbf{x})$. Perhaps some readers know that a vector field can be specified almost* completely if its divergence and curl are given everywhere in space. Thus we look for an equation specifying curl \mathbf{E} as a function of position. Such an equation, namely,

$$\nabla \times \mathbf{E} = 0 \quad (1.14)$$

follows directly from our generalized Coulomb's law (1.5):

$$\mathbf{E}(\mathbf{x}) = \int \rho(\mathbf{x}') \frac{(\mathbf{x} - \mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|^3} \, d^3x'$$

The vector factor in the integrand, viewed as a function of \mathbf{x} , is the negative gradient of the scalar $1/|\mathbf{x} - \mathbf{x}'|$:

$$\frac{(\mathbf{x} - \mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|^3} = -\nabla \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right)$$

Since the gradient operation involves \mathbf{x} , but not the integration variable \mathbf{x}' , it can be taken outside the integral sign. Then the field can be written

$$\mathbf{E}(\mathbf{x}) = -\nabla \int \frac{\rho(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} \, d^3x' \quad (1.15)$$

* Up to the gradient of a scalar function that satisfies the Laplace equation. See Section 1.9 on uniqueness.

Since the curl of the gradient of any well-behaved scalar function of position vanishes ($\nabla \times \nabla \psi = 0$, for all ψ), (1.14) follows immediately from (1.15).

Note that $\nabla \times \mathbf{E} = 0$ depends on the central nature of the force between charges, and on the fact that the force is a function of relative distances only, but does not depend on the inverse square nature.

In (1.15) the electric field (a vector) is derived from a scalar by the gradient operation. Since one function of position is easier to deal with than three, it is worth while concentrating on the scalar function and giving it a name. Consequently we define the *scalar potential* $\Phi(\mathbf{x})$ by the equation:

$$\mathbf{E} = -\nabla\Phi \quad (1.16)$$

Then (1.15) shows that the scalar potential is given in terms of the charge density by

$$\Phi(\mathbf{x}) = \int \frac{\rho(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3x' \quad (1.17)$$

where the integration is over all charges in the universe, and Φ is arbitrary only to the extent that a constant can be added to the right side of (1.17).

The scalar potential has a physical interpretation when we consider the work done on a test charge q in transporting it from one point (A) to another point (B) in the presence of an electric field $\mathbf{E}(\mathbf{x})$, as shown in Fig. 1.3. The force acting on the charge at any point is

$$\mathbf{F} = q\mathbf{E}$$

so that the work done in moving the charge from A to B is

$$W = -\int_A^B \mathbf{F} \cdot d\mathbf{l} = -q \int_A^B \mathbf{E} \cdot d\mathbf{l} \quad (1.18)$$

The minus sign appears because we are calculating the work done *on* the charge against the action of the field. With definition (1.16) the work can be written

$$W = q \int_A^B \nabla\Phi \cdot d\mathbf{l} = q \int_A^B d\Phi = q(\Phi_B - \Phi_A) \quad (1.19)$$

which shows that $q\Phi$ can be interpreted as the potential energy of the test charge in the electrostatic field.

Fig. 1.3

From (1.18) and (1.19) it can be seen that the line integral of the electric field between two points is independent of the path and is the negative of the potential difference between the points:

$$\int_A^B \mathbf{E} \cdot d\mathbf{l} = -(\Phi_B - \Phi_A) \quad (1.20)$$

This follows directly, of course, from definition (1.16). If the path is closed, the line integral is zero,

$$\oint \mathbf{E} \cdot d\mathbf{l} = 0 \quad (1.21)$$

a result that can also be obtained directly from Coulomb's law. Then application of *Stokes's theorem* [if $\mathbf{A}(\mathbf{x})$ is a well-behaved vector field, S is an arbitrary open surface, and C is the closed curve bounding S ,

$$\oint_C \mathbf{A} \cdot d\mathbf{l} = \int_S (\nabla \times \mathbf{A}) \cdot \mathbf{n} \, da$$

where $d\mathbf{l}$ is a line element of C , \mathbf{n} is the normal to S , and the path C is traversed in a right-hand screw sense relative to \mathbf{n}] leads immediately back to $\nabla \times \mathbf{E} = 0$.

1.6 Surface Distributions of Charges and Dipoles and Discontinuities in the Electric Field and Potential

One of the common problems in electrostatics is the determination of electric field or potential due to a given surface distribution of charges. Gauss's law (1.11) allows us to write down a partial result directly. If a surface S , with a unit normal \mathbf{n} directed from side 1 to side 2 of the surface, has a surface-charge density of $\sigma(\mathbf{x})$ (measured in statcoulombs per square centimeter) and electric fields \mathbf{E}_1 and \mathbf{E}_2 on either side of the surface, as shown in Fig. 1.4, then Gauss's

Fig. 1.4 Discontinuity in the normal component of electric field across a surface layer of charge.

law tells us immediately that

$$(\mathbf{E}_2 - \mathbf{E}_1) \cdot \mathbf{n} = 4\pi\sigma \quad (1.22)$$

This does not determine \mathbf{E}_1 and \mathbf{E}_2 unless there are no other sources of field and the geometry and form σ are especially simple. All that (1.22) says is that there is a discontinuity of $4\pi\sigma$ in the normal component of electric field in crossing a surface with a surface-charge density σ , the crossing being made in the direction of \mathbf{n} .

The tangential component of electric field can be shown to be continuous across a boundary surface by using (1.21) for the line integral of \mathbf{E} around a closed path. It is only necessary to take a rectangular path with negligible ends and one side on either side of the boundary.

An expression for the potential (and hence the field, by differentiation) at any point in space (not just at the surface) can be obtained from (1.17) by replacing ρd^3x by σda :

$$\Phi(\mathbf{x}) = \int_S \frac{\sigma(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} da' \quad (1.23)$$

For volume or surface distributions of charge the potential is everywhere continuous, even within the charge distribution. This can be shown from (1.23) or from the fact that \mathbf{E} is bounded, even though discontinuous across a surface distribution of charge. With point or line charges, or dipole layers, the potential is no longer continuous, as will be seen immediately.

Another problem of interest is the potential due to a dipole-layer distribution on a surface S . A dipole layer can be imagined as being formed by letting the surface S have a surface-charge density $\sigma(\mathbf{x})$ on it, and another surface S' , lying close to S , have an equal and opposite surface-charge density on it at neighboring points, as shown in Fig. 1.5. The dipole-layer distribution of strength $D(\mathbf{x})$ is formed by letting S' approach infinitesimally close to S while the surface-charge density $\sigma(\mathbf{x})$ becomes infinite in such a manner that the product of $\sigma(\mathbf{x})$ and the local separation $d(\mathbf{x})$ of S and S' approaches the limit $D(\mathbf{x})$:

$$\lim_{d(\mathbf{x}) \rightarrow 0} \sigma(\mathbf{x}) d(\mathbf{x}) = D(\mathbf{x})$$

Fig. 1.5 Limiting process involved in creating a dipole layer.

Fig. 1.6 Dipole-layer geometry.

The direction of the dipole moment of the layer is normal to the surface S and in the direction going from negative to positive charge.

To find the potential due to a dipole layer we can consider a single dipole and then superpose a surface density of them, or we can obtain the same result by performing mathematically the limiting process described in words above on the surface-density expression (1.23). The first way is perhaps simpler, but the second gives useful practice in vector calculus. Consequently we proceed with the limiting process. With \mathbf{n} , the unit normal to the surface S , directed away from S' , as shown in Fig. 1.6, the potential due to the two close surfaces is

$$\Phi(\mathbf{x}) = \int_S \frac{\sigma(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} da' - \int_{S'} \frac{\sigma(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}' + \mathbf{n}d|} da''$$

For small d we can expand $|\mathbf{x} - \mathbf{x}' + \mathbf{n}d|^{-1}$. Consider the general expression $|\mathbf{x} + \mathbf{a}|^{-1}$, where $|\mathbf{a}| \ll |\mathbf{x}|$. We write a Taylor series expansion in three dimensions:

$$\frac{1}{|\mathbf{x} + \mathbf{a}|} = \frac{1}{x} + \mathbf{a} \cdot \nabla \left(\frac{1}{x} \right) + \dots$$

In this way we find that as $d \rightarrow 0$ the potential becomes

$$\Phi(\mathbf{x}) = \int_S D(\mathbf{x}') \mathbf{n} \cdot \nabla' \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) da' \quad (1.24)$$

In passing we note that the integrand in Eq. (1.24) is the potential of a point dipole with dipole moment $\mathbf{p} = \mathbf{n} D da'$. The potential at \mathbf{x} caused by a dipole \mathbf{p} at \mathbf{x}' is

$$\Phi(\mathbf{x}) \quad \Phi(\mathbf{x}) = \frac{\mathbf{p} \cdot (\mathbf{x} - \mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|^3} \quad (1.25)$$

Equation (1.24) has a simple geometrical interpretation. We note that

$$\mathbf{n} \cdot \nabla' \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) da' = -\frac{\cos \theta da'}{|\mathbf{x} - \mathbf{x}'|^2} = -d\Omega$$

where $d\Omega$ is the element of solid angle subtended at the observation point by the area element da' , as indicated in Fig. 1.7. Note that $d\Omega$ has a positive sign if θ is an acute angle, i.e., when the observation point views the "inner" side of the

Fig. 1.7 The potential at P due to the dipole layer D on the area element da' is just the negative product of D and the solid angle element $d\Omega$ subtended by da' at P .

dipole layer. The potential can be written:

$$\Phi(\mathbf{x}) = - \int_S D(\mathbf{x}') d\Omega \quad (1.26)$$

For a constant surface-dipole-moment density D , the potential is just the product of the moment and the solid angle subtended at the observation point by the surface, regardless of its shape.

There is a discontinuity in potential in crossing a double layer. This can be seen by letting the observation point come infinitesimally close to the double layer. The double layer is now imagined to consist of two parts, one being a small disc directly under the observation point. The disc is sufficiently small that it is sensibly flat and has constant surface-dipole-moment density D . Evidently the total potential can be obtained by linear superposition of the potential of the disc and that of the remainder. From (1.26) it is clear that the potential of the disc alone has a discontinuity of $4\pi D$ in crossing from the inner to the outer side, being $-2\pi D$ on the inner side and $+2\pi D$ on the outer. The potential of the remainder alone, with its hole where the disc fits in, is continuous across the plane of the hole. Consequently the total potential jump in crossing the surface is:

$$\Phi_2 - \Phi_1 = 4\pi D \quad (1.27)$$

This result is analogous to (1.22) for the discontinuity of electric field in crossing a surface-charge density. Equation (1.27) can be interpreted “physically” as a potential drop occurring “inside” the dipole layer, and can be calculated as the product of the field between the two layers of surface charge times the separation before the limit is taken.

1.7 Poisson and Laplace Equations

In Sections 1.4 and 1.5 it was shown that the behavior of an electrostatic field can be described by the two differential equations:

$$\nabla \cdot \mathbf{E} = 4\pi\rho \quad (1.13)$$

and

$$\nabla \times \mathbf{E} = 0 \quad (1.14)$$

the latter equation being equivalent to the statement that \mathbf{E} is the gradient of a scalar function, the scalar potential Φ :

$$\mathbf{E} = -\nabla\Phi \quad (1.16)$$

Equations (1.13) and (1.16) can be combined into one partial differential equation for the single function $\Phi(\mathbf{x})$:

$$\nabla^2\Phi = -4\pi\rho \quad (1.28)$$

This equation is called the *Poisson equation*. In regions of space where there is no charge density, the scalar potential satisfies the *Laplace equation*:

$$\nabla^2\Phi = 0 \quad (1.29)$$

We already have a solution for the scalar potential in expression (1.17):

$$\Phi(\mathbf{x}) = \int \frac{\rho(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3x' \quad (1.17)$$

To verify directly that this does indeed satisfy the Poisson equation (1.28) we operate with the Laplacian on both sides. Because it turns out that the resulting integrand is singular, we invoke a limiting procedure. Define the “ a -potential” $\Phi_a(\mathbf{x})$ by

$$\Phi_a(\mathbf{x}) = \int \frac{\rho(\mathbf{x}')}{\sqrt{(\mathbf{x} - \mathbf{x}')^2 + a^2}} d^3x'$$

The actual potential (1.17) is then the limit of the “ a -potential” as $a \rightarrow 0$. Taking the Laplacian of the “ a -potential” gives

$$\begin{aligned} \nabla^2\Phi_a(\mathbf{x}) &= \int \rho(\mathbf{x}') \nabla^2 \left(\frac{1}{\sqrt{r^2 + a^2}} \right) d^3x' \\ &= - \int \rho(\mathbf{x}') \left[\frac{3a^2}{(r^2 + a^2)^{5/2}} \right] d^3x' \end{aligned} \quad (1.30)$$

where $r = |\mathbf{x} - \mathbf{x}'|$. The square-bracketed expression is the negative Laplacian of $1/\sqrt{r^2 + a^2}$. It is well-behaved everywhere for nonvanishing a , but as a tends to zero it becomes infinite at $\mathbf{r} = 0$ and vanishes for $\mathbf{r} \neq 0$. It has a volume integral equal to 4π for arbitrary a . For the purposes of integration divide space into two regions by a sphere of fixed radius R centered on \mathbf{x} . Choose R such that $\rho(\mathbf{x}')$ changes little over the interior of the sphere, and imagine a much smaller than R and tending towards zero. If $\rho(\mathbf{x}')$ is such that (1.17) exists, the contribution to the integral from the exterior of the sphere will vanish like a^2 as $a \rightarrow 0$. We thus need consider only the contribution from inside the sphere. With a Taylor series expansion of the well-behaved $\rho(\mathbf{x}')$ around $\mathbf{x}' = \mathbf{x}$, one finds

$$\nabla^2\Phi_a(\mathbf{x}) = -4\pi \int_0^R \frac{3a^2}{(r^2 + a^2)^{5/2}} \left[\rho(\mathbf{x}) \frac{r^2}{6} \nabla^2\rho + \cdots \right] r^2 dr + O(a^2)$$

Direct integration yields

$$\nabla^2 \Phi_a(\mathbf{x}) = -4\pi \rho(\mathbf{x}) \left(1 + O(a^2/R^2)\right) + O(a^2, a^2 \log a) \nabla^2 \rho + \dots$$

In the limit $a \rightarrow 0$, we obtain the Poisson equation (1.28).

The singular nature of the Laplacian of $1/r$ can be exhibited formally in terms of a Dirac delta function. Since $\nabla^2(1/r) = 0$ for $r \neq 0$ and its volume integral is -4π , we can write the formal equation, $\nabla^2(1/r) = -4\pi \delta(\mathbf{x})$ or, more generally,

$$\nabla^2 \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) = -4\pi \delta(\mathbf{x} - \mathbf{x}') \quad (1.31)$$

1.8 Green's Theorem

If electrostatic problems always involved localized discrete or continuous distributions of charge with no boundary surfaces, the general solution (1.17) would be the most convenient and straightforward solution to any problem. There would be no need of the Poisson or Laplace equation. In actual fact, of course, many, if not most, of the problems of electrostatics involve finite regions of space, with or without charge inside, and with prescribed boundary conditions on the bounding surfaces. These boundary conditions may be simulated by an appropriate distribution of charges outside the region of interest (perhaps at infinity), but (1.17) becomes inconvenient as a means of calculating the potential, except in simple cases (e.g., method of images).

To handle the boundary conditions it is necessary to develop some new mathematical tools, namely, the identities or theorems due to George Green (1824). These follow as simple applications of the divergence theorem. The divergence theorem:

$$\int_V \nabla \cdot \mathbf{A} \, d^3x = \oint_S \mathbf{A} \cdot \mathbf{n} \, da$$

applies to any well-behaved vector field \mathbf{A} defined in the volume V bounded by the closed surface S . Let $\mathbf{A} = \phi \nabla \psi$, where ϕ and ψ are arbitrary scalar fields. Now

$$\nabla \cdot (\phi \nabla \psi) = \phi \nabla^2 \psi + \nabla \phi \cdot \nabla \psi \quad (1.32)$$

and

$$\phi \nabla \psi \cdot \mathbf{n} = \phi \frac{\partial \psi}{\partial n} \quad (1.33)$$

where $\partial/\partial n$ is the normal derivative at the surface S (directed outwards from inside the volume V). When (1.32) and (1.33) are substituted into the divergence

theorem, there results *Green's first identity*:

$$\int_V (\phi \nabla^2 \psi + \nabla \phi \cdot \nabla \psi) d^3x = \oint_S \phi \frac{\partial \psi}{\partial n} da \quad (1.34)$$

If we write down (1.34) again with ϕ and ψ interchanged, and then subtract it from (1.34), the $\nabla \phi \cdot \nabla \psi$ terms cancel, and we obtain *Green's second identity* or *Green's theorem*:

$$\int_V (\phi \nabla^2 \psi - \psi \nabla^2 \phi) d^3x = \oint_S \left[\phi \frac{\partial \psi}{\partial n} - \psi \frac{\partial \phi}{\partial n} \right] da \quad (1.35)$$

The Poisson differential equation for the potential can be converted into an integral equation if we choose a particular ψ , namely $1/R \equiv 1/|\mathbf{x} - \mathbf{x}'|$, where \mathbf{x} is the observation point and \mathbf{x}' is the integration variable. Further, we put $\phi = \Phi$, the scalar potential, and make use of $\nabla^2 \Phi = -4\pi\rho$. From (1.31) we know that $\nabla^2(1/R) = -4\pi\delta(\mathbf{x} - \mathbf{x}')$, so that (1.35) becomes

$$\int_V \left[-4\pi\Phi(\mathbf{x}') \delta(\mathbf{x} - \mathbf{x}') + \frac{4\pi}{R} \rho(\mathbf{x}') \right] d^3x' = \oint_S \left[\Phi \frac{\partial}{\partial n'} \left(\frac{1}{R} \right) - \frac{1}{R} \frac{\partial \Phi}{\partial n'} \right] da'$$

If the point \mathbf{x} lies within the volume V , we obtain:

$$\Phi(\mathbf{x}) = \int_V \frac{\rho(\mathbf{x}')}{R} d^3x' + \frac{1}{4\pi} \oint_S \left[\frac{1}{R} \frac{\partial \Phi}{\partial n'} - \Phi \frac{\partial}{\partial n'} \left(\frac{1}{R} \right) \right] da' \quad (1.36)$$

If \mathbf{x} lies outside the surface S , the left-hand side of (1.36) is zero.* [Note that this is consistent with the interpretation of the surface integral as being the potential due to a surface-charge density $\sigma = (1/4\pi)(\partial\Phi/\partial n')$ and a dipole layer $D = -(1/4\pi)\Phi$. The discontinuities in electric field and potential (1.22) and (1.27) across the surface then lead to zero field and zero potential outside the volume V .]

Two remarks are in order about result (1.36). First, if the surface S goes to infinity and the electric field on S falls off faster than R^{-1} , then the surface integral vanishes and (1.36) reduces to the familiar result (1.17). Second, for a charge-free volume the potential anywhere inside the volume (a solution of the Laplace equation) is expressed in (1.36) in terms of the potential and its normal derivative only on the surface of the volume. This rather surprising result is not a solution to a boundary-value problem, but only an integral statement, since the arbitrary specification of both Φ and $\partial\Phi/\partial n$ (*Cauchy boundary conditions*) is an overspecification of the problem. This will be discussed in detail in the next sections, where techniques yielding solutions for appropriate boundary conditions will be developed using *Green's theorem* (1.35).

*The reader may complain that (1.36) has been obtained in an illegal fashion since $1/|\mathbf{x} - \mathbf{x}'|$ is not well-behaved inside the volume V . Rigor can be restored by using a limiting process, as in the previous section, or by excluding a small sphere around the offending point, $\mathbf{x} = \mathbf{x}'$. The result is still (1.36).

1.9 Uniqueness of the Solution with Dirichlet or Neumann Boundary Conditions

The question arises as to what are the boundary conditions appropriate for the Poisson (or Laplace) equation in order that a unique and well-behaved (i.e., physically reasonable) solution exist inside the bounded region. Physical experience leads us to believe that specification of the potential on a closed surface (e.g., a system of conductors held at different potentials) defines a unique potential problem. This is called a *Dirichlet problem*, or *Dirichlet boundary conditions*. Similarly it is plausible that specification of the electric field (normal derivative of the potential) everywhere on the surface (corresponding to a given surface-charge density) also defines a unique problem. Specification of the normal derivative is known as the *Neumann boundary condition*. We now proceed to prove these expectations by means of Green's first identity (1.34).

We want to show the uniqueness of the solution of the Poisson equation, $\nabla^2\Phi = -4\pi\rho$, inside a volume V subject to either Dirichlet or Neumann boundary conditions on the closed bounding surface S . We suppose, to the contrary, that there exist two solutions Φ_1 and Φ_2 satisfying the same boundary conditions. Let

$$U = \Phi_2 - \Phi_1 \quad (1.37)$$

Then $\nabla^2 U = 0$ inside V , and $U = 0$ or $\partial U / \partial n = 0$ on S for Dirichlet and Neumann boundary conditions, respectively. From Green's first identity (1.34), with $\phi = \psi = U$, we find

$$\int_V (U \nabla^2 U + \nabla U \cdot \nabla U) d^3x = \oint_S U \frac{\partial U}{\partial n} da \quad (1.38)$$

With the specified properties of U , this reduces (for both types of boundary conditions) to:

$$\int_V |\nabla U|^2 d^3x = 0$$

which implies $\nabla U = 0$. Consequently, inside V , U is constant. For Dirichlet boundary conditions, $U = 0$ on S so that, inside V , $\Phi_1 = \Phi_2$ and the solution is unique. Similarly, for Neumann boundary conditions, the solution is unique, apart from an unimportant arbitrary additive constant.

From the right-hand side of (1.38) it is evident that there is also a unique solution to a problem with mixed boundary conditions (i.e., Dirichlet over part of the surface S , and Neumann over the remaining part).

It should be clear that a solution to the Poisson equation with both Φ and $\partial\Phi/\partial n$ specified arbitrarily on a closed boundary (Cauchy boundary conditions) does not exist, since there are unique solutions for Dirichlet and Neumann conditions separately and these will in general not be consistent. This can be verified with (1.36). With arbitrary values of Φ and $\partial\Phi/\partial n$ inserted on the

right-hand side, it can be shown that the values of $\Phi(\mathbf{x})$ and $\nabla\Phi(\mathbf{x})$ as \mathbf{x} approaches the surface are in general inconsistent with the assumed boundary values. The question of whether Cauchy boundary conditions on an *open* surface define a unique electrostatic problem requires more discussion than is warranted here. The reader may refer to *Morse and Feshbach*, Section 6.2, pp. 692–706, or to *Sommerfeld, Partial Differential Equations in Physics*, Chapter II, for a detailed discussion of these questions. The conclusion is that electrostatic problems are specified only by Dirichlet or Neumann boundary conditions on a closed surface (part or all of which may be at infinity, of course).

1.10 Formal Solution of Electrostatic Boundary-Value Problem with Green Function

The solution of the Poisson or Laplace equation in a finite volume V with either Dirichlet or Neumann boundary conditions on the bounding surface S can be obtained by means of Green's theorem (1.35) and so-called "Green functions."

In obtaining result (1.36)—not a solution—we chose the function ψ to be $1/|\mathbf{x}-\mathbf{x}'|$, it being the potential of a unit point charge, satisfying the equation:

$$\nabla'^2\left(\frac{1}{|\mathbf{x}-\mathbf{x}'|}\right) = -4\pi\delta(\mathbf{x}-\mathbf{x}') \quad (1.31)$$

The function $1/|\mathbf{x}-\mathbf{x}'|$ is only one of a class of functions depending on the variables \mathbf{x} and \mathbf{x}' , and called *Green functions*, which satisfy (1.31). In general,

$$\nabla'^2 G(\mathbf{x}, \mathbf{x}') = -4\pi\delta(\mathbf{x}-\mathbf{x}') \quad (1.39)$$

where

$$G(\mathbf{x}, \mathbf{x}') = \frac{1}{|\mathbf{x}-\mathbf{x}'|} + F(\mathbf{x}, \mathbf{x}') \quad (1.40)$$

with the function F satisfying the Laplace equation inside the volume V :

$$\nabla'^2 F(\mathbf{x}, \mathbf{x}') = 0 \quad (1.41)$$

In facing the problem of satisfying the prescribed boundary conditions on Φ or $\partial\Phi/\partial n$, we can find the key by considering result (1.36). As has been pointed out already, this is not a solution satisfying the correct type of boundary conditions because both Φ and $\partial\Phi/\partial n$ appear in the surface integral. It is at best an integral relation for Φ . With the generalized concept of a Green function and its additional freedom [via the function $F(\mathbf{x}, \mathbf{x}')$], there arises the possibility that we can use Green's theorem with $\psi = G(\mathbf{x}, \mathbf{x}')$ and choose $F(\mathbf{x}, \mathbf{x}')$ to eliminate one or the other of the two surface integrals, obtaining a result which involves only Dirichlet or Neumann boundary conditions. Of course, if the necessary $G(\mathbf{x}, \mathbf{x}')$ depended in detail on the exact form of the boundary conditions, the method would have little generality. As will be seen immediately, this is not required, and $G(\mathbf{x}, \mathbf{x}')$ satisfies rather simple boundary conditions on S .

With Green's theorem (1.35), $\phi = \Phi$, $\psi = G(\mathbf{x}, \mathbf{x}')$, and the specified properties of G (1.39), it is simple to obtain the generalization of (1.36):

$$\Phi(\mathbf{x}) = \int_V \rho(\mathbf{x}') G(\mathbf{x}, \mathbf{x}') d^3x' + \frac{1}{4\pi} \oint_S \left[G(\mathbf{x}, \mathbf{x}') \frac{\partial \Phi}{\partial n'} - \Phi(\mathbf{x}') \frac{\partial G(\mathbf{x}, \mathbf{x}')}{\partial n'} \right] da' \quad (1.42)$$

The freedom available in the definition of G (1.40) means that we can make the surface integral depend only on the chosen type of boundary conditions. Thus, for *Dirichlet boundary conditions* we demand:

$$G_D(\mathbf{x}, \mathbf{x}') = 0 \quad \text{for } \mathbf{x}' \text{ on } S \quad (1.43)$$

Then the first term in the surface integral in (1.42) vanishes and the solution is

$$\Phi(\mathbf{x}) = \int_V \rho(\mathbf{x}') G_D(\mathbf{x}, \mathbf{x}') d^3x' - \frac{1}{4\pi} \oint_S \Phi(\mathbf{x}') \frac{\partial G_D}{\partial n'} da' \quad (1.44)$$

For *Neumann boundary conditions* we must be more careful. The obvious choice of boundary condition on $G(\mathbf{x}, \mathbf{x}')$ seems to be

$$\frac{\partial G_N}{\partial n'}(\mathbf{x}, \mathbf{x}') = 0 \quad \text{for } \mathbf{x}' \text{ on } S$$

since that makes the second term in the surface integral in (1.42) vanish, as desired. But an application of Gauss's theorem to (1.39) shows that

$$\oint_S \frac{\partial G}{\partial n'} da' = -4\pi$$

Consequently the simplest allowable boundary condition on G_N is

$$\frac{\partial G_N}{\partial n'}(\mathbf{x}, \mathbf{x}') = -\frac{4\pi}{S} \quad \text{for } \mathbf{x}' \text{ on } S \quad (1.45)$$

where S is the total area of the boundary surface. Then the solution is

$$\Phi(\mathbf{x}) = \langle \Phi \rangle_S + \int_V \rho(\mathbf{x}') G_N(\mathbf{x}, \mathbf{x}') d^3x' + \frac{1}{4\pi} \oint_S \frac{\partial \Phi}{\partial n'} G_N da' \quad (1.46)$$

where $\langle \Phi \rangle_S$ is the average value of the potential over the whole surface. The customary Neumann problem is the so-called "exterior problem" in which the volume V is bounded by two surfaces, one closed and finite, the other at infinity. Then the surface area S is infinite; the boundary condition (1.45) becomes homogeneous; the average value $\langle \Phi \rangle_S$ vanishes.

We note that the Green functions satisfy simple boundary conditions (1.43) or (1.45) which do not depend on the detailed form of the Dirichlet (or Neumann) boundary values. Even so, it is often rather involved (if not impossible) to determine $G(\mathbf{x}, \mathbf{x}')$ because of its dependence on the shape of the surface S . We will encounter such problems in Chapter 2 and 3.

The mathematical symmetry property $G(\mathbf{x}, \mathbf{x}') = G(\mathbf{x}', \mathbf{x})$ can be proved for the

Green functions satisfying the Dirichlet boundary condition (1.43) by means of Green's theorem with $\phi = G(\mathbf{x}, \mathbf{y})$ and $\psi = G(\mathbf{x}', \mathbf{y})$, where \mathbf{y} is the integration variable. Since the Green function, as a function of one of its variables, is a potential due to a unit point charge, the symmetry merely represents the physical interchangeability of the source and the observation points. For Neumann boundary conditions the symmetry is not automatic, but can be imposed as a separate requirement.

As a final, important remark we note the physical meaning of $F(\mathbf{x}, \mathbf{x}')$. It is a solution of the Laplace equation inside V and so represents the potential of a system of charges *external to the volume* V . It can be thought of as the potential due to an external distribution of charges so chosen as to satisfy the homogeneous boundary conditions of zero potential (or zero normal derivative) on the surface S when combined with the potential of a point charge at the source point \mathbf{x}' . Since the potential at a point \mathbf{x} on the surface due to the point charge depends on the position of the source point, the external distribution of charge $F(\mathbf{x}, \mathbf{x}')$ must also depend on the "parameter" \mathbf{x}' . From this point of view, we see that the method of images (to be discussed in Chapter 2) is a physical equivalent of the determination of the appropriate $F(\mathbf{x}, \mathbf{x}')$ to satisfy the boundary conditions (1.43) or (1.45). For the Dirichlet problem with conductors, $F(\mathbf{x}, \mathbf{x}')$ can also be interpreted as the potential due to the surface-charge distribution induced on the conductors by the presence of a point charge at the source point \mathbf{x}' .

1.11 Electrostatic Potential Energy and Energy Density, Capacitance

In Section 1.5 it was shown that the product of the scalar potential and the charge of a point object could be interpreted as potential energy. More precisely, if a point charge q_i is brought from infinity to a point \mathbf{x}_i in a region of localized electric fields described by the scalar potential Φ (which vanishes at infinity), the work done on the charge (and hence its potential energy) is given by

$$W_i = q_i \Phi(\mathbf{x}_i) \quad (1.47)$$

The potential Φ can be viewed as produced by an array of $(n-1)$ charges $q_j (j=1, 2, \dots, n-1)$ at positions \mathbf{x}_j . Then

$$\Phi(\mathbf{x}_i) = \sum_{j=1}^{n-1} \frac{q_j}{|\mathbf{x}_i - \mathbf{x}_j|} \quad (1.48)$$

so that the potential energy of the charge q_i is

$$W_i = q_i \sum_{j=1}^{n-1} \frac{q_j}{|\mathbf{x}_i - \mathbf{x}_j|} \quad (1.49)$$

The *total* potential energy of all the charges due to all the forces acting between

them is:

$$W = \sum_{i=1}^n \sum_{j < i} \frac{q_i q_j}{|\mathbf{x}_i - \mathbf{x}_j|} \quad (1.50)$$

as can be seen most easily by adding each charge in succession. A more symmetric form can be written by summing over i and j unrestricted, and then dividing by 2:

$$W = \frac{1}{2} \sum_i \sum_j \frac{q_i q_j}{|\mathbf{x}_i - \mathbf{x}_j|} \quad (1.51)$$

It is understood that $i = j$ terms (infinite “self-energy” terms) are omitted in the double sum.

For a continuous charge distribution [or, in general, using the Dirac delta functions (1.6)] the potential energy takes the form:

$$W = \frac{1}{2} \iint \frac{\rho(\mathbf{x})\rho(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3x d^3x' \quad (1.52)$$

Another expression, equivalent to (1.52), can be obtained by noting that one of the integrals in (1.52) is just the scalar potential (1.17). Therefore

$$W = \frac{1}{2} \int \rho(\mathbf{x})\Phi(\mathbf{x}) d^3x \quad (1.53)$$

Equations (1.51), (1.52), and (1.53) express the electrostatic potential energy in terms of the positions of the charges and so emphasize the interactions between charges via Coulomb forces. An alternative, and very fruitful, approach is to emphasize the electric field and to interpret the energy as being stored in the electric field surrounding the charges. To obtain this latter form, we make use of the Poisson equation to eliminate the charge density from (1.53):

$$W = \frac{-1}{8\pi} \int \Phi \nabla^2 \Phi d^3x$$

Integration by parts leads to the result:

$$W = \frac{1}{8\pi} \int |\nabla \Phi|^2 d^3x = \frac{1}{8\pi} \int |\mathbf{E}|^2 d^3x \quad (1.54)$$

where the integration is over all space. In (1.54) all explicit reference to charges has gone, and the energy is expressed as an integral of the square of the electric field over all space. This leads naturally to the identification of the integrand as an energy density w :

$$w = \frac{1}{8\pi} |\mathbf{E}|^2 \quad (1.55)$$

This expression for energy density is intuitively reasonable, since regions of high fields “must” contain considerable energy.

Fig. 1.8

There is perhaps one puzzling thing about (1.55). The energy density is positive definite. Consequently its volume integral is necessarily nonnegative. This seems to contradict our impression from (1.51) that the potential energy of two charges of opposite sign is negative. The reason for this apparent contradiction is that (1.54) and (1.55) contain “self-energy” contributions to the energy density, whereas the double sum in (1.51) does not. To illustrate this, consider two point charges q_1 and q_2 located at \mathbf{x}_1 and \mathbf{x}_2 , as in Fig. 1.8. The electric field at the point P with coordinate \mathbf{x} is

$$\mathbf{E} = \frac{q_1(\mathbf{x} - \mathbf{x}_1)}{|\mathbf{x} - \mathbf{x}_1|^3} + \frac{q_2(\mathbf{x} - \mathbf{x}_2)}{|\mathbf{x} - \mathbf{x}_2|^3}$$

so that the energy density (1.55) is

$$w = \frac{q_1^2}{8\pi |\mathbf{x} - \mathbf{x}_1|^4} + \frac{q_2^2}{8\pi |\mathbf{x} - \mathbf{x}_2|^4} + \frac{q_1 q_2 (\mathbf{x} - \mathbf{x}_1) \cdot (\mathbf{x} - \mathbf{x}_2)}{4\pi |\mathbf{x} - \mathbf{x}_1|^3 |\mathbf{x} - \mathbf{x}_2|^3} \quad (1.56)$$

Clearly the first two terms are self-energy contributions. To show that the third term gives the proper result for the interaction potential energy we integrate over all space:

$$W_{\text{int}} = \frac{q_1 q_2}{4\pi} \int \frac{(\mathbf{x} - \mathbf{x}_1) \cdot (\mathbf{x} - \mathbf{x}_2)}{|\mathbf{x} - \mathbf{x}_1|^3 |\mathbf{x} - \mathbf{x}_2|^3} d^3x \quad (1.57)$$

A change of integration variable to $\boldsymbol{\rho} = (\mathbf{x} - \mathbf{x}_1)/|\mathbf{x}_1 - \mathbf{x}_2|$ yields

$$W_{\text{int}} = \frac{q_1 q_2}{|\mathbf{x}_1 - \mathbf{x}_2|} \times \frac{1}{4\pi} \int \frac{\boldsymbol{\rho} \cdot (\boldsymbol{\rho} + \mathbf{n})}{\rho^3 |\boldsymbol{\rho} + \mathbf{n}|^3} d^3\rho \quad (1.58)$$

where \mathbf{n} is a unit vector in the direction $(\mathbf{x}_1 - \mathbf{x}_2)$. Using the fact that $(\boldsymbol{\rho} + \mathbf{n})/|\boldsymbol{\rho} + \mathbf{n}|^3 = -\nabla_{\boldsymbol{\rho}}(1/|\boldsymbol{\rho} + \mathbf{n}|)$, the dimensionless integral can easily be shown to have the value 4π , so that the interaction energy reduces to the expected value.

Forces acting between charged bodies can be obtained by calculating the change in the total electrostatic energy of the system under small virtual displacements. Examples of this are discussed in the problems. Care must be taken to exhibit the energy in a form showing clearly those factors which vary with a change in configuration and those which are kept constant.

As a simple illustration we calculate the force per unit area on the surface of a conductor with a surface-charge density $\sigma(\mathbf{x})$. In the immediate neighborhood of

the surface the energy density is

$$w = \frac{1}{8\pi} |\mathbf{E}|^2 = 2\pi\sigma^2 \quad (1.59)$$

If we now imagine a small outward displacement Δx of an elemental area Δa of the conducting surface, the electrostatic energy decreases by an amount which is the product of energy density w and the excluded volume $\Delta x \Delta a$:

$$\Delta W = -2\pi\sigma^2 \Delta a \Delta x \quad (1.60)$$

This means that there is an outward force per unit area equal to $2\pi\sigma^2 = w$ at the surface of the conductor. This result is normally derived by taking the product of the surface-charge density and the electric field, with care taken to eliminate the electric field due to the element of surface-charge density itself.

For a system of n conductors, each with potential V_i and total charge Q_i ($i = 1, 2, \dots, n$) in otherwise empty space, the electrostatic potential energy can be expressed in terms of the potentials alone and certain geometrical quantities called coefficients of capacity. For a given configuration of the conductors, the linear functional dependence of the potential on the charge density implies that the potential of the i th conductor can be written as

$$V_i = \sum_{j=1}^n p_{ij} Q_j \quad (i = 1, 2, \dots, n)$$

where the p_{ij} depend on the geometry of the conductors. These n equations can be inverted to yield the charge on the i th conductor in terms of all the potentials:

$$Q_i = \sum_{j=1}^n C_{ij} V_j \quad (i = 1, 2, \dots, n) \quad (1.61)$$

The coefficients C_{ii} are called capacities or capacitances while the C_{ij} , $i \neq j$, are called coefficients of induction. The *capacitance of a conductor is therefore the total charge on the conductor when it is maintained at unit potential, all other conductors being held at zero potential*. Sometimes the capacitance of a system of conductors is also defined. For example, the capacitance of two conductors carrying equal and opposite charges in the presence of other grounded conductors is defined as the ratio of the charge on one conductor to the potential difference between them. The equations (1.61) can be used to express this capacitance in terms of the coefficients C_{ij} .

The potential energy (1.53) for the system of conductors is

$$W = \frac{1}{2} \sum_{i=1}^n Q_i V_i = \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n C_{ij} V_i V_j \quad (1.62)$$

The expression of the energy in terms of the potentials V_i and the C_{ij} , or in terms of the charges Q_i and the coefficients p_{ij} , permits the application of variational methods to obtain approximate values of capacitances. It can be shown (see

Problems 1.17 and 1.18) that there are variational principles giving upper and lower bounds on C_{ii} . The principles permit estimation with known error of the capacitances of relatively involved configurations of conductors. High-speed computational techniques permit the use of elaborate trial functions involving several parameters. It must be remarked, however, that the need for a Green function satisfying Dirichlet boundary conditions in the lower bound makes the error estimate nontrivial. Further consideration of this technique for calculating capacitances is left to the problems at the end of this and subsequent chapters.

PROBLEMS

1.1 Use Gauss's theorem (and Eq. (1.21) if necessary) to prove the following:

(a) Any excess charge placed on a conductor must lie entirely on its surface. (A conductor by definition contains charges capable of moving freely under the action of applied electric fields.)

(b) A closed, hollow conductor shields its interior from fields due to charges outside, but does not shield its exterior from the fields due to charges placed inside it.

(c) The electric field at the surface of a conductor is normal to the surface and has a magnitude $4\pi\sigma$, where σ is the charge density per unit area on the surface.

- 1.2 The Dirac delta function in three dimensions can be taken as the improper limit as $\alpha \rightarrow 0$ of the Gaussian function

$$D(\alpha; x, y, z) = (2\pi)^{-3/2} \alpha^{-3} \exp \left[-\frac{1}{2\alpha^2} (x^2 + y^2 + z^2) \right]$$

Consider a general orthogonal coordinate system specified by the surfaces, $u = \text{constant}$, $v = \text{constant}$, $w = \text{constant}$, with length elements du/U , dv/V , dw/W in the three perpendicular directions. Show that

$$\delta(\mathbf{x} - \mathbf{x}') = \delta(u - u') \delta(v - v') \delta(w - w') \cdot UVW$$

by considering the limit of the above Gaussian. Note that as $\alpha \rightarrow 0$ only the infinitesimal length element need be used for the distance between the points in the exponent.

- 1.3 Using Dirac delta functions in the appropriate coordinates, express the following charge distributions as three-dimensional charge densities $\rho(\mathbf{x})$.
- In spherical coordinates, a charge Q uniformly distributed over a spherical shell of radius R .
 - In cylindrical coordinates, a charge λ per unit length uniformly distributed over a cylindrical surface of radius b .
 - In cylindrical coordinates, a charge Q spread uniformly over a flat circular disc of negligible thickness and radius R .
 - The same as (c), but using spherical coordinates.
- 1.4 Each of three charged spheres of radius a , one conducting, one having a uniform charge density within its volume, and one having a spherically symmetric charge density which varies radially as r^n ($n > -3$), has a total charge Q . Use Gauss's theorem to obtain the electric fields both inside and outside each sphere. Sketch the behavior of the fields as a function of radius for the first two spheres, and for the third with $n = -2, +2$.
- 1.5 The time-average potential of a neutral hydrogen atom is given by

$$\Phi = q \frac{e^{-\alpha r}}{r} \left(1 + \frac{\alpha r}{2} \right)$$

where q is the magnitude of the electronic charge, and $\alpha^{-1} = a_0/2$, a_0 being the Bohr radius. Find the distribution of charge (both continuous and discrete) which will give this potential and interpret your result physically.

- 1.6 A simple capacitor is a device formed by two insulated conductors adjacent to each other. If equal and opposite charges are placed on the conductors, there will be a certain difference of potential between them. The ratio of the magnitude of the charge on one conductor to the magnitude of the potential difference is called the capacitance (in electrostatic units it is measured in centimeters). Using Gauss's law, calculate the capacitance of
- two large, flat, conducting sheets of area A , separated by a small distance d ;
 - two concentric conducting spheres with radii a, b ($b > a$);
 - two concentric conducting cylinders of length L , large compared to their radii a, b ($b > a$).
 - What is the inner diameter of the outer conductor in an air-filled coaxial cable

whose center conductor is a cylindrical wire of diameter 1 mm and whose capacitance is 0.5 micromicrofarad/cm? 0.05 micromicrofarad/cm?

- 1.7 Two long, cylindrical conductors of radii a_1 and a_2 are parallel and separated by a distance d which is large compared with either radius. Show that the capacitance per unit length is given approximately by

$$C \approx \left(4 \ln \frac{d}{a} \right)^{-1}$$

where a is the geometrical mean of the two radii.

Approximately what gauge wire (state diameter in millimeters) would be necessary to make a two-wire transmission line with a capacitance of $0.1 \mu\mu\text{f/cm}$ if the separation of the wires was 0.5 cm? 1.5 cm? 5.0 cm?

- 1.8 (a) For the three capacitor geometries in Problem 1.6 calculate the total electrostatic energy and express it alternatively in terms of the equal and opposite charges Q and $-Q$ placed on the conductors and the potential difference between them.
 (b) Sketch the energy density of the electrostatic field in each case as a function of the appropriate linear coordinate.
- 1.9 Calculate the attractive force between conductors in the parallel plate capacitor (Problem 1.6a) and the parallel cylinder capacitor (Problem 1.7) for
 (a) fixed charges on each conductor;
 (b) fixed potential difference between conductors.
- 1.10 Prove the *mean value theorem*: For charge-free space the value of the electrostatic potential at any point is equal to the average of the potential over the surface of any sphere centered on that point.
- 1.11 Use Gauss's theorem to prove that at the surface of a curved charged conductor the normal derivative of the electric field is given by

$$\frac{1}{E} \frac{\partial E}{\partial n} = - \left(\frac{1}{R_1} + \frac{1}{R_2} \right)$$

where R_1 and R_2 are the principal radii of curvature of the surface.

- 1.12 Prove *Green's reciprocity theorem*: If Φ is the potential due to a volume-charge density ρ within a volume V and a surface-charge density σ on the conducting surface S bounding the volume V , while Φ' is the potential due to another charge distribution ρ' and σ' , then

$$\int_V \rho \Phi' d^3x + \int_S \sigma \Phi' da = \int_V \rho' \Phi d^3x + \int_S \sigma' \Phi da$$

- 1.13 Two infinite grounded parallel conducting planes are separated by a distance d . A point charge q is placed between the planes. Use the reciprocity theorem of Green to prove that the total induced charge on one of the planes is equal to $(-q)$ times the fractional perpendicular distance of the point charge from the other plane. (*Hint*: Choose as your comparison electrostatic problem with the same surfaces one whose charge densities and potential are known and simple.)
- 1.14 A volume V is bounded by a surface S consisting of several separate surfaces (conductors) S_i , one perhaps at infinity, each held at potential V_i . Let $\Psi(\mathbf{x})$ be a well-behaved function in V and on S , with a value equal to V_i on each surface S_i , but otherwise arbitrary for the present. Define the energylike quantity, otherwise arbit-

ary for the present. Define the energylike quantity,

$$W[\Psi] = \frac{1}{8\pi} \int_V |\nabla\Psi|^2 d^3x$$

Prove the following theorem:

$W[\Psi]$, which is nonnegative by definition, is stationary and an absolute minimum if and only if Ψ satisfies the Laplace equation inside V and takes on the specified values V_i on the surfaces S_i .

- 1.15 Prove *Thomson's theorem*: If a number of surfaces are fixed in position and a given total charge is placed on each surface, then the electrostatic energy in the region bounded by the surfaces is an absolute minimum when the charges are placed so that every surface is an equipotential, as happens when they are conductors.
- 1.16 Prove the following theorem: If a number of conducting surfaces are fixed in position with a given total charge on each, the introduction of an uncharged, insulated conductor into the region bounded by the surfaces lowers the electrostatic energy.
- 1.17 Consider a configuration of conductors as in problem 1.14 with one conductor held at *unit* potential and all the other conductors at zero potential.
- (a) Show that the capacitance of the one conductor is given by

$$C = \frac{1}{4\pi} \int_V |\nabla\Phi|^2 d^3x$$

where $\Phi(\mathbf{x})$ is the solution for the potential.

(b) Use the theorem of Problem 1.14 to show that the true capacitance C is always less than or equal to the quantity

$$C[\Psi] = \frac{1}{4\pi} \int_V |\nabla\Psi|^2 d^3x$$

where Ψ is any trial function satisfying the boundary conditions on the conductors. This is a variational principle for the capacitance that yields an *upper bound*.

- 1.18 Consider the configuration of conductors of Problem 1.17, with all conductors except S_1 held at zero potential.
- (a) Show that the potential $\Phi(\mathbf{x})$ anywhere in the volume V and on any of the surfaces S_i can be written

$$\Phi(\mathbf{x}) = \oint_{S_1} \sigma_1(\mathbf{x}') G(\mathbf{x}, \mathbf{x}') d^3x'$$

where $\sigma_1(\mathbf{x}')$ is the surface charge density on S_1 and $G(\mathbf{x}, \mathbf{x}')$ is the Green function potential for a point charge in the presence of all the surfaces that are held at zero potential (but with S_1 absent). Show also that the electrostatic energy is

$$W = \frac{1}{2} \oint_{S_1} da \oint_{S_1} da' \sigma_1(\mathbf{x}) G(\mathbf{x}, \mathbf{x}') \sigma_1(\mathbf{x}')$$

where the integrals are only over the surface S_1 .

(b) Show that the variational expression

$$C^{-1}[\sigma] = \frac{\oint_{S_1} da \oint_{S_1} da' \sigma(\mathbf{x}) G(\mathbf{x}, \mathbf{x}') \sigma(\mathbf{x}')}{\left[\oint_{S_1} \sigma(\mathbf{x}) da \right]^2}$$

with an arbitrary integrable function $\sigma(\mathbf{x})$ defined on S_1 , is stationary for small variations of σ away from σ_1 . Use Thomson's theorem to prove that the reciprocal of $C^{-1}[\sigma]$ gives a *lower bound* to the true capacitance of the conductor S_1 .

1.19 For the cylindrical capacitor of Problem 1.6(c), evaluate the variational upper bound of Problem 1.17(b) with the naive trial function, $\Psi_1(\rho) = (b - \rho)/(b - a)$. Compare the variational result with the exact result for $b/a = 1.5, 2, 3$. Explain the trend of your results in terms of the functional form of Ψ_1 . An improved trial function is treated by Collin, pp. 151–152.

1.20 In estimating the capacitance of a given configuration of conductors, comparison with known capacitances is often helpful. Consider two configurations of n conductors in which the $(n-1)$ conductors held at zero potential are the same, but the one conductor whose capacitance we wish to know is different. In particular, let the conductor in one configuration have a closed surface S_1 and in the other configuration have surface S'_1 , with S'_1 totally inside S_1 .

(a) Use the theorem of Problem 1.14 and the variational principle of Problem 1.17 to prove that the capacitance C' of the conductor with surface S'_1 is less than or equal to the capacitance C of the conductor with surface S_1 that encloses S'_1 .

(b) Set upper and lower limits for the capacitance of a conducting cube of side a . Compare your limits and also their average with the numerical value, $C \approx 0.655a$.

Boundary-Value Problems in Electrostatics: I

Many problems in electrostatics involve boundary surfaces on which either the potential or the surface-charge density is specified. The formal solution of such problems was presented in Section 1.10, using the method of Green functions. In practical situations (or even rather idealized approximations to practical situations) the discovery of the correct Green function is sometimes easy and sometimes not. Consequently a number of approaches to electrostatic boundary-value problems have been developed, some of which are only remotely connected to the Green function method. In this chapter we will examine two of these special techniques: (1) the method of images, which is closely related to the use of Green functions; (2) expansion in orthogonal functions, an approach directly through the differential equation and rather remote from the direct construction of a Green function. A major omission is the use of complex-variable techniques, including conformal mapping, for the treatment of two-dimensional problems. The topic is important, but lack of space and the existence of self-contained discussions elsewhere accounts for its absence. The interested reader may consult the references cited at the end of the chapter.

2.1 Method of Images

The method of images concerns itself with the problem of one or more point charges in the presence of boundary surfaces, for example, conductors either grounded or held at fixed potentials. Under favorable conditions it is possible to infer from the geometry of the situation that a small number of suitably placed charges of appropriate magnitudes, external to the region of interest, can simulate the required boundary conditions. These charges are called *image charges*, and the replacement of the actual problem with boundaries by an enlarged region with image charges but not boundaries is called the *method of images*. The image charges must be external to the volume of interest, since their

Fig. 2.1 Solution by method of images. The original potential problem is on the left, the equivalent-image problem on the right.

potentials must be solutions of the Laplace equation inside the volume; the “particular integral” (i.e., solution of the Poisson equation) is provided by the sum of the potentials of the charges inside the volume.

A simple example is a point charge located in front of an infinite plane conductor at zero potential, as shown in Fig. 2.1. It is clear that this is equivalent to the problem of the original charge and an equal and opposite charge located at the mirror-image point behind the plane defined by the position of the conductor.

2.2 Point Charge in the Presence of a Grounded Conducting Sphere

As an illustration of the method of images we consider the problem illustrated in Fig. 2.2 of a point charge q located at \mathbf{y} relative to the origin around which is centered a grounded conducting sphere of radius a . We seek the potential $\Phi(\mathbf{x})$ such that $\Phi(|\mathbf{x}|=a)=0$. By symmetry it is evident that the image charge q'

Fig. 2.2 Conducting sphere of radius a , with charge q and image charge q' .

(assuming that only one image is needed) will lie on the ray from the origin to the charge q . If we consider the charge q outside the sphere, the image position \mathbf{y}' will lie inside the sphere. The potential due to the charges q and q' is:

$$\Phi(\mathbf{x}) = \frac{q}{|\mathbf{x} - \mathbf{y}|} + \frac{q'}{|\mathbf{x} - \mathbf{y}'|} \quad (2.1)$$

We now must try to choose q' and $|\mathbf{y}'|$ such that this potential vanishes at $|\mathbf{x}| = a$. If \mathbf{n} is a unit vector in the direction \mathbf{x} , and \mathbf{n}' a unit vector in the direction \mathbf{y} , then

$$\Phi(\mathbf{x}) = \frac{q}{|x\mathbf{n} - y\mathbf{n}'|} + \frac{q'}{|x\mathbf{n} - y'\mathbf{n}'|} \quad (2.2)$$

If x is factored out of the first term and y' out of the second, the potential at $x = a$ becomes:

$$\Phi(x = a) = -\frac{q}{a \left| \mathbf{n} - \frac{y}{a} \mathbf{n}' \right|} + \frac{q'}{y' \left| \mathbf{n}' - \frac{a}{y'} \mathbf{n} \right|} \quad (2.3)$$

From the form of (2.3) it will be seen that the choices:

$$\frac{q}{a} = -\frac{q'}{y'}, \quad \frac{y}{a} = \frac{a}{y'}$$

make $\Phi(x = a) = 0$, for all possible values of $\mathbf{n} \cdot \mathbf{n}'$. Hence the magnitude and position of the image charge are

$$q' = -\frac{a}{y} q, \quad y' = \frac{a^2}{y} \quad (2.4)$$

We note that, as the charge q is brought closer to the sphere, the image charge grows in magnitude and moves out from the center of the sphere. When q is just outside the surface of the sphere, the image charge is equal and opposite in magnitude and lies just beneath the surface.

Now that the image charge has been found, we can return to the original problem of a charge q outside a grounded conducting sphere and consider various effects. The actual charge density induced on the surface of the sphere can be calculated from the normal derivative of Φ at the surface:

$$\sigma = -\frac{1}{4\pi} \frac{\partial \Phi}{\partial x} \Big|_{x=a} = -\frac{q}{4\pi a^2} \left(\frac{a}{y} \right) \frac{\left(1 - \frac{a^2}{y^2} \right)}{\left(1 + \frac{a^2}{y^2} - 2 \frac{a}{y} \cos \gamma \right)^{3/2}} \quad (2.5)$$

where γ is the angle between \mathbf{x} and \mathbf{y} . This charge density in units of $-q/4\pi a^2$ is shown plotted in Fig. 2.3 as a function of γ for two values of y/a . The concentration of charge in the direction of the point charge q is evident, especially for $y/a = 2$. It is easy to show by direct integration that the total

Fig. 2.3 Surface-charge density σ induced on the grounded sphere of radius a due to the presence of a point charge q located a distance y away from the center of the sphere. σ is plotted in units of $-q/4\pi a^2$ as function of the angular position γ away from the radius to the charge for $y=2a$, $4a$.

induced charge on the sphere is equal to the magnitude of the image charge, as it must according to Gauss's law.

The force acting on the charge q can be calculated in different ways. One (the easiest) way is to write down immediately the force between the charge q and the image charge q' . The distance between them is $y - y' = y(1 - a^2/y^2)$. Hence the attractive force, according to Coulomb's law, is:

$$|\mathbf{F}| = \frac{q^2}{a^2} \left(\frac{a}{y} \right)^3 \left(1 - \frac{a^2}{y^2} \right)^{-2} \quad (2.6)$$

For large separations the force is an inverse cube law, but close to the sphere it is proportional to the inverse square of the distance away from the surface of the sphere.

The alternative method for obtaining the force is to calculate the total force acting on the surface of the sphere. The force on each element of area da is $2\pi\sigma^2 da$, where σ is given by (2.5), as indicated in Fig. 2.4. But from symmetry it is clear that only the component parallel to the radius vector from the center of

Fig. 2.4

the sphere to q contributes to the total force. Hence the total force acting on the sphere (equal and opposite to the force acting on q) is given by the integral:

$$|\mathbf{F}| = \frac{q^2}{8\pi a^2} \left(\frac{a}{y}\right)^2 \left(1 - \frac{a^2}{y^2}\right)^2 \int \frac{\cos \gamma}{\left(1 + \frac{a^2}{y^2} - \frac{2a}{y} \cos \gamma\right)^3} d\Omega \quad (2.7)$$

Integration immediately yields (2.6).

The whole discussion has been based on the understanding that the point charge q is *outside* the sphere. Actually, the results apply equally for the charge q *inside* the sphere. The only change necessary is in the surface-charge density (2.5), where the normal derivative out of the conductor is now radially inwards, implying a change in sign. The reader may transcribe all the formulas, remembering that now $y \leq a$. The angular distributions of surface charge are similar to those of Fig. 2.3, but the total induced surface charge is evidently equal to $-q$, independent of y .

2.3 Point Charge in the Presence of a Charged, Insulated, Conducting Sphere

In the previous section we considered the problem of a point charge q near a grounded sphere and saw that a surface-charge density was induced on the sphere. This charge was of total amount $q' = -aq/y$, and was distributed over the surface in such a way as to be in equilibrium under all forces acting.

If we wish to consider the problem of an insulated conducting sphere with total charge Q in the presence of a point charge q , we can build up the solution for the potential by linear superposition. In an operational sense, we can imagine that we start with the grounded conducting sphere (with its charge q' distributed over its surface). We then disconnect the ground wire and add to the sphere an amount of charge $(Q - q')$. This brings the total charge on the sphere up to Q . To find the potential we merely note that the added charge $(Q - q')$ will distribute itself *uniformly* over the surface, since the electrostatic forces due to the point charge q are already balanced by the charge q' . Hence the potential due to the added charge $(Q - q')$ will be the same as if a point charge of that magnitude were at the origin, at least for points outside the sphere.

The potential is the superposition of (2.1) and the potential of a point charge $(Q-q')$ at the origin:

$$\Phi(\mathbf{x}) = \frac{q}{|\mathbf{x}-\mathbf{y}|} - \frac{aq}{y \left| \mathbf{x} - \frac{a^2}{y^2} \mathbf{y} \right|} + \frac{Q + \frac{a}{y}q}{|\mathbf{x}|} \quad (2.8)$$

The force acting on the charge q can be written down directly from Coulomb's law. It is directed along the radius vector to q and has the magnitude:

$$\mathbf{F} = \frac{q}{y^2} \left[Q - \frac{qa^3(2y^2 - a^2)}{y(y^2 - a^2)^2} \right] \frac{\mathbf{y}}{y} \quad (2.9)$$

In the limit of $y \gg a$, the force reduces to the usual Coulomb's law for two small charged bodies. But close to the sphere the force is modified because of the induced charge distribution on the surface of the sphere. Figure 2.5 shows the force as a function of distance for various ratios of Q/q . The force is expressed in

Fig. 2.5 The force on a point charge q due to an insulated, conducting sphere of radius a carrying a total charge Q . Positive values mean a repulsion, negative an attraction. The asymptotic dependence of the force has been divided out. Fy^2/q^2 is plotted versus y/a for $Q/q = -1, 0, 1, 3$. Regardless of the value of Q , the force is always attractive at close distances because of the induced surface charge.

units of q^2/y^2 ; positive (negative) values correspond to a repulsion (attraction). If the sphere is charged oppositely to q , or is uncharged, the force is attractive at all distances. Even if the charge Q is the same sign as q , however, the force becomes attractive at very close distances. In the limit of $Q \gg q$, the point of zero force (unstable equilibrium point) is very close to the sphere, namely, at $y \approx a(1 + \frac{1}{2}\sqrt{q/Q})$. Note that the asymptotic value of the force is attained as soon as the charge q is more than a few radii away from the sphere.

This example exhibits a general property which explains why an excess of charge on the surface does not immediately leave the surface because of mutual repulsion of the individual charges. As soon as an element of charge is removed from the surface, the image force tends to attract it back. If sufficient work is done, of course, charge can be removed from the surface to infinity. The work function of a metal is in large part just the work done against the attractive image force in order to remove an electron from the surface.

2.4 Point Charge Near a Conducting Sphere at Fixed Potential

Another problem which can be discussed easily is that of a point charge near a conducting sphere held at a fixed potential V . The potential is the same as for the charged sphere, except that the charge ($Q - q'$) at the center is replaced by a charge (Va). This can be seen from (2.8), since at $|\mathbf{x}| = a$ the first two terms cancel and the last term will be equal to V as required. Thus the potential is

$$\Phi(\mathbf{x}) = \frac{q}{|\mathbf{x} - \mathbf{y}|} - \frac{aq}{y \left| \mathbf{x} - \frac{a^2}{y^2} \mathbf{y} \right|} + \frac{Va}{|\mathbf{x}|} \quad (2.10)$$

The force on the charge q due to the sphere at fixed potential is

$$\mathbf{F} = \frac{q}{y^2} \left[Va - \frac{qay^3}{(y^2 - a^2)^2} \right] \frac{\mathbf{y}}{y} \quad (2.11)$$

For corresponding values of Va/q and Q/q this force is very similar to that of the charged sphere, shown in Fig. 2.5, although the approach to the asymptotic value (Vaq/y^2) is more gradual. For $Va \gg q$, the unstable equilibrium point has the equivalent location $y \approx a(1 + \frac{1}{2}\sqrt{q/Va})$.

2.5 Conducting Sphere in a Uniform Electric Field by Method of Images

As a final example of the method of images we consider a conducting sphere of radius a in a uniform electric field E_0 . A uniform field can be thought of as being produced by appropriate positive and negative charges at infinity. For example, if there are two charges $\pm Q$, located at positions $z = \mp R$, as shown in Fig. 2.6a,

Fig. 2.6 Conducting sphere in a uniform electric field by the method of images.

then in a region near the origin whose dimensions are very small compared to R there is an approximately constant electric field $E_0 \approx 2Q/R^2$ parallel to the z axis. In the limit as $R, Q \rightarrow \infty$, with Q/R^2 constant, this approximation becomes exact.

If now a conducting sphere of radius a is placed at the origin, the potential will be that due to the charges $\pm Q$ at $\mp R$ and their images $\mp Qa/R$ at $z = \mp a^2/R$:

$$\Phi = \frac{Q}{(r^2 + R^2 + 2rR \cos \theta)^{1/2}} - \frac{Q}{(r^2 + R^2 - 2rR \cos \theta)^{1/2}} \\ - \frac{aQ}{R \left(r^2 + \frac{a^4}{R^2} + \frac{2a^2r}{R} \cos \theta \right)^{1/2}} + \frac{aQ}{R \left(r^2 + \frac{a^4}{R^2} - \frac{2a^2r}{R} \cos \theta \right)^{1/2}} \quad (2.12)$$

where Φ has been expressed in terms of the spherical coordinates of the observation point. In the first two terms R is much larger than r by assumption. Hence we can expand the radicals after factoring out R^2 . Similarly, in the third and fourth terms, we can factor out r^2 and then expand. The result is:

$$\Phi = \left[-\frac{2Q}{R^2} r \cos \theta + \frac{2Q}{R^2} \frac{a^3}{r^2} \cos \theta \right] + \dots \quad (2.13)$$

where the omitted terms vanish in the limit $R \rightarrow \infty$. In that limit $2Q/R^2$ becomes the applied uniform field, so that the potential is

$$\Phi = -E_0 \left(r - \frac{a^3}{r^2} \right) \cos \theta \quad (2.14)$$

The first term ($-E_0 z$) is, of course, just the potential of a uniform field E_0 which could have been written down directly instead of the first two terms in (2.12). The second is the potential due to the induced surface charge density or, equivalently, the image charges. Note that the image charges form a dipole of strength $D = Qa/R \times 2a^2/R = E_0 a^3$. The induced surface-charge density is

$$\sigma = -\frac{1}{4\pi} \frac{\partial \Phi}{\partial r} \bigg|_{r=a} = \frac{3}{4\pi} E_0 \cos \theta \quad (2.15)$$

We note that the surface integral of this charge density vanishes, so that there is no difference between a grounded and an insulated sphere.

2.6 Green Function for the Sphere, General Solution for the Potential

In preceding sections the problem of a conducting sphere in the presence of a point charge has been discussed by the method of images. As was mentioned in Section 1.10, the potential due to a unit charge and its image (or images), chosen to satisfy homogeneous boundary conditions, is just the Green function (1.43 or 1.45) appropriate for Dirichlet or Neumann boundary conditions. In $G(\mathbf{x}, \mathbf{x}')$ the variable \mathbf{x}' refers to the location P' of the unit charge, while the variable \mathbf{x} is the point P at which the potential is being evaluated. These coordinates and the sphere are shown in Fig. 2.7. For Dirichlet boundary conditions on the sphere of radius a the potential due to a unit charge and its image is given by (2.1) with $q = 1$ and relations (2.4). Transforming variables appropriately, we

Fig. 2.7

obtain the Green function:

$$G(\mathbf{x}, \mathbf{x}') = \frac{1}{|\mathbf{x} - \mathbf{x}'|} - \frac{a}{x' \left| \mathbf{x} - \frac{a^2}{x'^2} \mathbf{x}' \right|} \quad (2.16)$$

In terms of spherical coordinates this can be written:

$$G(\mathbf{x}, \mathbf{x}') = \frac{1}{(x^2 + x'^2 - 2xx' \cos \gamma)^{1/2}} - \frac{1}{\left(\frac{x^2 x'^2}{a^2} + a^2 - 2xx' \cos \gamma \right)^{1/2}} \quad (2.17)$$

where γ is the angle between \mathbf{x} and \mathbf{x}' . The symmetry in the variables \mathbf{x} and \mathbf{x}' is obvious in the form (2.17), as is the condition that $G=0$ if either \mathbf{x} or \mathbf{x}' is on the surface of the sphere.

For solution (1.44) of the Poisson equation we need not only G , but also $\partial G / \partial n'$. Remembering that \mathbf{n}' is the unit normal outwards from the volume of interest, i.e., inwards along \mathbf{x}' toward the origin, we have

$$\left. \frac{\partial G}{\partial n'} \right|_{x'=a} = - \frac{(x^2 - a^2)}{a(x^2 + a^2 - 2ax \cos \gamma)^{3/2}} \quad (2.18)$$

[Note that this is essentially the induced surface-charge density (2.5).] Hence the solution of the Laplace equation *outside* a sphere with the potential specified on its surface is, according to (1.44),

$$\Phi(\mathbf{x}) = \frac{1}{4\pi} \int \Phi(a, \theta', \phi') \frac{a(x^2 - a^2)}{(x^2 + a^2 - 2ax \cos \gamma)^{3/2}} d\Omega' \quad (2.19)$$

where $d\Omega'$ is the element of solid angle at the point (a, θ', ϕ') and $\cos \gamma = \cos \theta \cos \theta' + \sin \theta \sin \theta' \cos(\phi - \phi')$. For the *interior* problem, the normal derivative is radially outwards, so that the sign of $\partial G / \partial n'$ is opposite to (2.18). This is equivalent to replacing the factor $(x^2 - a^2)$ by $(a^2 - x^2)$ in (2.19). For a problem with a charge distribution, we must add to (2.19) the appropriate integral in (1.44), with the Green function (2.17).

2.7 Conducting Sphere with Hemispheres at Different Potentials

As an example of the solution (2.19) for the potential outside a sphere with prescribed values of potential on its surface, we consider the conducting sphere of radius a made up of two hemispheres separated by a small insulating ring. The hemispheres are kept at different potentials. It will suffice to consider the potentials as $\pm V$, since arbitrary potentials can be handled by superposition of the solution for a sphere at fixed potential over its whole surface. The insulating ring lies in the $z=0$ plane, as shown in Fig. 2.8, with the upper (lower) hemisphere at potential $+V$ ($-V$).

Fig. 2.8

From (2.19) the solution for $\Phi(x, \theta, \phi)$ is given by the integral:

$$\Phi(x, \theta, \phi) = \frac{V}{4\pi} \int_0^{2\pi} d\phi' \left\{ \int_0^1 d(\cos \theta') - \int_{-1}^0 d(\cos \theta') \right\} \frac{a(x^2 - a^2)}{(a^2 + x^2 - 2ax \cos \gamma)^{3/2}} \quad (2.20)$$

By a suitable change of variables in the second integral ($\theta' \rightarrow \pi - \theta'$, $\phi' \rightarrow \phi' + \pi$), this can be cast in the form:

$$\Phi(x, \theta, \phi) = \frac{Va(x^2 - a^2)}{4\pi} \int_0^{2\pi} d\phi' \int_0^1 d(\cos \theta') [(a^2 + x^2 - 2ax \cos \gamma)^{-3/2} - (a^2 + x^2 + 2ax \cos \gamma)^{-3/2}] \quad (2.21)$$

Because of the complicated dependence of $\cos \gamma$ on the angles (θ', ϕ') and (θ, ϕ) , equation (2.21) cannot in general be integrated in closed form.

As a special case we consider the potential on the positive z axis. Then $\cos \gamma = \cos \theta'$ since $\theta = 0$. The integration is elementary, and the potential can be shown to be

$$\Phi(z) = V \left[1 - \frac{(z^2 - a^2)}{z\sqrt{z^2 + a^2}} \right] \quad (2.22)$$

At $z = a$, this reduces to $\Phi = V$ as required, while at large distances it goes asymptotically as $\Phi \approx 3Va^2/2z^2$.

In the absence of a closed expression for the integrals in (2.21), we can expand the denominator in power series and integrate term by term. Factoring out $(a^2 + x^2)$ from each denominator, we obtain

$$\Phi(x, \theta, \phi) = \frac{Va(x^2 - a^2)}{4\pi(x^2 + a^2)^{3/2}} \int_0^{2\pi} d\phi' \int_0^1 d(\cos \theta') [(1 - 2\alpha \cos \gamma)^{-3/2} - (1 + 2\alpha \cos \gamma)^{-3/2}] \quad (2.23)$$

where $\alpha = ax/(a^2 + x^2)$. We observe that in the expansion of the radicals only odd powers of $\alpha \cos \gamma$ will appear:

$$[(1 - 2\alpha \cos \gamma)^{-3/2} - (1 + 2\alpha \cos \gamma)^{-3/2}] = 6\alpha \cos \gamma + 35\alpha^3 \cos^3 \gamma + \dots \quad (2.24)$$

It is now necessary to integrate odd powers of $\cos \gamma$ over $d\phi' d(\cos \theta')$:

$$\left. \begin{aligned} \int_0^{2\pi} d\phi' \int_0^1 d(\cos \theta') \cos \gamma &= \pi \cos \theta \\ \int_0^{2\pi} d\phi' \int_0^1 d(\cos \theta') \cos^3 \gamma &= \frac{\pi}{4} \cos \theta (3 - \cos^2 \theta) \end{aligned} \right\} \quad (2.25)$$

If (2.24) and (2.25) are inserted into (2.23), the potential becomes

$$\Phi(x, \theta, \phi) = \frac{3Va^2}{2x^2} \left(\frac{x^3(x^2 - a^2)}{(x^2 + a^2)^{5/2}} \right) \cos \theta \left[1 + \frac{35}{24} \frac{a^2 x^2}{(a^2 + x^2)^2} (3 - \cos^2 \theta) + \dots \right] \quad (2.26)$$

We note that only odd powers of $\cos \theta$ appear, as required by the symmetry of the problem. If the expansion parameter is (a^2/x^2) , rather than α^2 , the series takes on the form:

$$\Phi(x, \theta, \phi) = \frac{3Va^2}{2x^2} \left[\cos \theta - \frac{7a^2}{12x^2} \left(\frac{5}{2} \cos^3 \theta - \frac{3}{2} \cos \theta \right) + \dots \right] \quad (2.27)$$

For large values of x/a this expansion converges rapidly and so is a useful representation for the potential. Even for $x/a = 5$, the second term in the series is only of the order of 2 per cent. It is easily verified that, for $\cos \theta = 1$, expression (2.27) agrees with the expansion of (2.22) for the potential on the axis. [The particular choice of angular factors in (2.27) is dictated by the definitions of the Legendre polynomials. The two factors are, in fact, $P_1(\cos \theta)$ and $P_3(\cos \theta)$, and the expansion of the potential is one in Legendre polynomials of odd order. We shall establish this in a systematic fashion in Section 3.3.]

2.8 Orthogonal Functions and Expansions

The representation of solutions of potential problems (or any mathematical physics problem) by expansions in orthogonal functions forms a powerful technique that can be used in a large class of problems. The particular orthogonal set chosen depends on the symmetries or near symmetries involved. To recall the general properties of orthogonal functions and expansions in terms of them, we consider an interval (a, b) in a variable ξ with a set of real or complex functions $U_n(\xi)$, $n = 1, 2, \dots$, square integrable and orthogonal on the interval (a, b) . The orthogonality condition on the functions $U_n(\xi)$ is expressed by

$$\int_a^b U_n^*(\xi) U_m(\xi) d\xi = 0, \quad m \neq n \quad (2.28)$$

If $n = m$, the integral is nonzero. We assume that the functions are normalized so that the integral is unity. Then the functions are said to be *orthonormal*, and they satisfy

$$\int_a^b U_n^*(\xi) U_m(\xi) d\xi = \delta_{nm} \quad (2.29)$$

An arbitrary function $f(\xi)$, square integrable on the interval (a, b) , can be expanded in a series of the orthonormal functions $U_n(\xi)$. If the number of terms in the series is finite (say N),

$$f(\xi) \leftrightarrow \sum_{n=1}^N a_n U_n(\xi) \quad (2.30)$$

then we can ask for the “best” choice of coefficients a_n so that we get the “best” representation of the function $f(\xi)$. If “best” is defined as minimizing the mean square error M_N :

$$M_N = \int_a^b \left| f(\xi) - \sum_{n=1}^N a_n U_n(\xi) \right|^2 d\xi \quad (2.31)$$

it is easy to show that the coefficients are given by

$$a_n = \int_a^b U_n^*(\xi) f(\xi) d\xi \quad (2.32)$$

where the orthonormality condition (2.29) has been used. This is the standard result for the coefficients in an orthonormal function expansion.

If the number of terms N in series (2.30) is taken larger and larger, we intuitively expect that our series representation of $f(\xi)$ is “better” and “better.” Our intuition will be correct provided the set of orthonormal functions is *complete*, completeness being defined by the requirement that there exist a finite number N_0 such that for $N > N_0$ the mean square error M_N can be made smaller than any arbitrarily small positive quantity. Then the series representation

$$\sum_{n=1}^{\infty} a_n U_n(\xi) = f(\xi) \quad (2.33)$$

with a_n given by (2.32) is said to *converge in the mean* to $f(\xi)$. Physicists generally leave the difficult job of proving completeness of a given set of functions to the mathematicians. All orthonormal sets of functions normally occurring in mathematical physics have been proved to be complete.

Series (2.33) can be rewritten with the explicit form (2.32) for the coefficients a_n :

$$f(\xi) = \int_a^b \left\{ \sum_{n=1}^{\infty} U_n^*(\xi') U_n(\xi) \right\} f(\xi') d\xi' \quad (2.34)$$

Since this represents any function $f(\xi)$ on the interval (a, b) , it is clear that the sum of bilinear terms $U_n^*(\xi') U_n(\xi)$ must exist only in the neighborhood of $\xi' = \xi$. In fact, it must be true that

$$\sum_{n=1}^{\infty} U_n^*(\xi') U_n(\xi) = \delta(\xi' - \xi) \quad (2.35)$$

This is the so-called *completeness* or *closure relation*. It is analogous to the

orthonormality condition (2.29), except that the roles of the continuous variable ξ and the discrete index n have been interchanged.

The most famous orthogonal functions are the sines and cosines, an expansion in terms of them being a *Fourier series*. If the interval in x is $(-a/2, a/2)$, the orthonormal functions are

$$\sqrt{\frac{2}{a}} \sin\left(\frac{2\pi mx}{a}\right), \quad \sqrt{\frac{2}{a}} \cos\left(\frac{2\pi mx}{a}\right)$$

where m is an integer and for $m=0$ the cosine function is $1/\sqrt{a}$. The series equivalent to (2.33) is customarily written in the form:

$$f(x) = \frac{1}{2}A_0 + \sum_{m=1}^{\infty} \left[A_m \cos\left(\frac{2\pi mx}{a}\right) + B_m \sin\left(\frac{2\pi mx}{a}\right) \right] \quad (2.36)$$

where

$$\begin{aligned} A_m &= \frac{2}{a} \int_{-a/2}^{a/2} f(x) \cos\left(\frac{2\pi mx}{a}\right) dx \\ B_m &= \frac{2}{a} \int_{-a/2}^{a/2} f(x) \sin\left(\frac{2\pi mx}{a}\right) dx \end{aligned} \quad (2.37)$$

If the interval spanned by the orthonormal set has more than one dimension, formulas (2.28)–(2.33) have obvious generalizations. Suppose that the space is two dimensional, and that the variable ξ ranges over the interval (a, b) while the variable η has the interval (c, d) . The orthonormal functions in each dimension are $U_n(\xi)$ and $V_m(\eta)$. Then the expansion of an arbitrary function $f(\xi, \eta)$ is

$$f(\xi, \eta) = \sum_n \sum_m a_{nm} U_n(\xi) V_m(\eta) \quad (2.38)$$

where

$$a_{nm} = \int_a^b d\xi \int_c^d d\eta U_n^*(\xi) V_m^*(\eta) f(\xi, \eta) \quad (2.39)$$

If the interval (a, b) becomes infinite, the set of orthogonal functions $U_n(\xi)$ may become a continuum of functions, rather than a denumerable set. Then the Kronecker delta symbol in (2.29) becomes a Dirac delta function. An important example is the *Fourier integral*. Start with the orthonormal set of complex exponentials,

$$U_m(x) = \frac{1}{\sqrt{a}} e^{i(2\pi mx/a)} \quad (2.40)$$

$m=0, \pm 1, \pm 2, \dots$, on the interval $(-a/2, a/2)$, with the expansion:

$$f(x) = \frac{1}{\sqrt{a}} \sum_{m=-\infty}^{\infty} A_m e^{i(2\pi mx/a)} \quad (2.41)$$

where

$$A_m = \frac{1}{\sqrt{a}} \int_{-a/2}^{a/2} e^{-i(2\pi mx'/a)} f(x') dx' \quad (2.42)$$

Then let the interval become infinite ($a \rightarrow \infty$), at the same time transforming

$$\left. \begin{aligned} \frac{2\pi m}{a} &\rightarrow k \\ \sum_m &\rightarrow \int_{-\infty}^{\infty} dm = \frac{a}{2\pi} \int_{-\infty}^{\infty} dk \\ A_m &\rightarrow \sqrt{\frac{2\pi}{a}} A(k) \end{aligned} \right\} \quad (2.43)$$

The resulting expansion, equivalent to (2.41), is the *Fourier integral*,

$$f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} A(k) e^{ikx} dk \quad (2.44)$$

where

$$A(k) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-ikx} f(x) dx \quad (2.45)$$

The orthogonality condition is

$$\frac{1}{2\pi} \int_{-\infty}^{\infty} e^{i(k-k')x} dx = \delta(k-k') \quad (2.46)$$

while the completeness relation is

$$\frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ik(x-x')} dk = \delta(x-x') \quad (2.47)$$

These last integrals serve as convenient representations of a delta function. We note in (2.44)–(2.47) the complete equivalence of the two continuous variables x and k .

2.9 Separation of Variables, Laplace Equation in Rectangular Coordinates

The partial differential equations of mathematical physics are often solved conveniently by a method called *separation of variables*. In the process, one often generates orthogonal sets of functions which are useful in their own right. Equations involving the three-dimensional Laplacian operator are known to be separable in eleven different coordinate systems (see *Morse and Feshbach*, pp. 509, 655). We will discuss only three of these in any detail—rectangular, spherical, and cylindrical—and will begin with the simplest, rectangular coordinates.

The Laplace equation in rectangular coordinates is

$$\frac{\partial^2 \Phi}{\partial x^2} + \frac{\partial^2 \Phi}{\partial y^2} + \frac{\partial^2 \Phi}{\partial z^2} = 0 \quad (2.48)$$

A solution of this *partial* differential equation can be found in terms of three *ordinary* differential equations, all of the same form, by the assumption that the potential can be represented by a product of three functions, one for each coordinate:

$$\Phi(x, y, z) = X(x)Y(y)Z(z) \quad (2.49)$$

Substitution into (2.48) and division of the result by (2.49) yields

$$\frac{1}{X(x)} \frac{d^2 X}{dx^2} + \frac{1}{Y(y)} \frac{d^2 Y}{dy^2} + \frac{1}{Z(z)} \frac{d^2 Z}{dz^2} = 0 \quad (2.50)$$

where total derivatives have replaced partial derivatives, since each term involves a function of one variable only. If (2.50) is to hold for arbitrary values of the independent coordinates, each of the three terms must be separately constant:

$$\left. \begin{aligned} \frac{1}{X} \frac{d^2 X}{dx^2} &= -\alpha^2 \\ \frac{1}{Y} \frac{d^2 Y}{dy^2} &= -\beta^2 \\ \frac{1}{Z} \frac{d^2 Z}{dz^2} &= \gamma^2 \end{aligned} \right\} \quad (2.51)$$

where

$$\alpha^2 + \beta^2 = \gamma^2$$

If we arbitrarily choose α^2 and β^2 to be positive, then the solutions of the three ordinary differential equations (2.51) are $\exp(\pm i\alpha x)$, $\exp(\pm i\beta y)$, $\exp(\pm\sqrt{\alpha^2 + \beta^2} z)$. The potential (2.49) can thus be built up from the product solutions:

$$\Phi = e^{\pm i\alpha x} e^{\pm i\beta y} e^{\pm\sqrt{\alpha^2 + \beta^2} z} \quad (2.52)$$

At this stage α and β are completely arbitrary. Consequently (2.52), by linear superposition, represents a very large class of solutions to the Laplace equation.

To determine α and β it is necessary to impose specific boundary conditions on the potential. As an example, consider a rectangular box, located as shown in Fig. 2.9, with dimensions (a, b, c) in the (x, y, z) directions. All surfaces of the box are kept at zero potential, except the surface $z = c$, which is at a potential $V(x, y)$. It is required to find the potential everywhere inside the box. Starting with the requirement that $\Phi = 0$ for $x = 0$, $y = 0$, $z = 0$, it is easy to see that the required forms of X , Y , Z are

$$\left. \begin{aligned} X &= \sin \alpha x \\ Y &= \sin \beta y \\ Z &= \sinh(\sqrt{\alpha^2 + \beta^2} z) \end{aligned} \right\} \quad (2.53)$$

Fig. 2.9 Hollow, rectangular box with five sides at zero potential, while the sixth ($z=c$) has the specified potential $\Phi = V(x, y)$.

In order that $\Phi=0$ at $x=a$ and $y=b$, it is necessary that $\alpha a = n\pi$ and $\beta b = m\pi$. With the definitions,

$$\left. \begin{aligned} \alpha_n &= \frac{n\pi}{a} \\ \beta_m &= \frac{m\pi}{b} \\ \gamma_{nm} &= \pi \sqrt{\frac{n^2}{a^2} + \frac{m^2}{b^2}} \end{aligned} \right\} \quad (2.54)$$

we can write the partial potential Φ_{nm} , satisfying all the boundary conditions except one,

$$\Phi_{nm} = \sin(\alpha_n x) \sin(\beta_m y) \sinh(\gamma_{nm} z) \quad (2.55)$$

The potential can be expanded in terms of these Φ_{nm} with initially arbitrary coefficients (to be chosen to satisfy the final boundary condition):

$$\Phi(x, y, z) = \sum_{n,m=1}^{\infty} A_{nm} \sin(\alpha_n x) \sin(\beta_m y) \sinh(\gamma_{nm} z) \quad (2.56)$$

There remains only the boundary condition $\Phi = V(x, y)$ at $z=c$:

$$V(x, y) = \sum_{n,m=1}^{\infty} A_{nm} \sin(\alpha_n x) \sin(\beta_m y) \sinh(\gamma_{nm} c) \quad (2.57)$$

This is just a double Fourier series for the function $V(x, y)$. Consequently the coefficients A_{nm} are given by:

$$A_{nm} = \frac{4}{ab \sinh(\gamma_{nm} c)} \int_0^a dx \int_0^b dy V(x, y) \sin(\alpha_n x) \sin(\beta_m y) \quad (2.58)$$

If the rectangular box has potentials different from zero on all six sides, the required solution for the potential inside the box can be obtained by a linear superposition of six solutions, one for each side, equivalent to (2.56) and (2.58). The problem of the solution of the Poisson equation, that is, the potential inside the box with a charge distribution inside, as well as prescribed boundary conditions on the surface, requires the construction of the appropriate Green function, according to (1.43) and (1.44). Discussion of this topic will be deferred until we have treated the Laplace equation in spherical and cylindrical coordinates. For the moment, we merely note that solution (2.56) and (2.58) is equivalent to the surface integral in the Green function solution (1.44).

2.10 A Two-Dimensional Potential Problem, Summation of a Fourier Series

We now consider briefly the solution by separation of variables of the two-dimensional Laplace equation in Cartesian coordinates. By two-dimensional problems we mean those in which the potential can be assumed to be independent of one of the coordinates, say, z . This is usually only an approximation, but may hold true to high accuracy, as in a long uniform transmission line. If the potential is independent of z , the basic solutions of the previous section reduce to the products

$$e^{\pm i\alpha x} e^{\pm \alpha y}$$

where α is any real or complex constant. The imposition of boundary conditions on the potential will determine what values of α are permitted and the form of the linear superposition of different solutions required.

A simple problem that can be used to demonstrate the separation of variables technique and also establish connection with the use of complex variables is indicated in Fig. 2.10. The potential in the region, $0 \leq x \leq a$, $y \geq 0$, is desired, subject to the boundary conditions that $\Phi = 0$ at $x = 0$ and $x = a$, while $\Phi = V$ at $y = 0$ for $0 \leq x \leq a$ and $\Phi \rightarrow 0$ for large y . Inspection of the basic solutions shows that α is real and that, in order to have the potential vanish at $x = 0$ and $x = a$ for all y and as $y \rightarrow \infty$, the proper linear combinations are $e^{-\alpha y} \sin(\alpha x)$ with $\alpha = n\pi/a$. The linear combination of solutions satisfying the boundary conditions on three of the four boundary surfaces is thus

$$\Phi(x, y) = \sum_{n=1}^{\infty} A_n \exp(-n\pi y/a) \sin(n\pi x/a) \quad (2.59)$$

The coefficients A_n are determined by the requirement that $\Phi = V$ for $y = 0$, $0 \leq x \leq a$. As discussed in Section 2.8, the Fourier coefficients are

$$A_n = \frac{2}{a} \int_0^a \Phi(x, 0) \sin(n\pi x/a) dx \quad (2.60)$$

Fig. 2.10 Two-dimensional potential problem.

With $\Phi(x, 0) = V$, one finds

$$A_n = \frac{4V}{\pi n} \begin{cases} 1 & \text{for } n \text{ odd} \\ 0 & \text{for } n \text{ even} \end{cases}$$

The potential $\Phi(x, y)$ is therefore determined to be

$$\Phi(x, y) = \frac{4V}{\pi} \sum_{n \text{ odd}} \frac{1}{n} \exp(-n\pi y/a) \sin(n\pi x/a) \quad (2.61)$$

For small values of y many terms in the series are necessary to give an accurate approximation, but for $y \geq a/\pi$ it is evident that only the first few terms are appreciable. The potential rapidly approaches its asymptotic form given by the first term,

$$\Phi(x, y) \rightarrow \frac{4V}{\pi} \exp(-\pi y/a) \sin(\pi x/a) \quad (2.62)$$

Paranthenetically, we remark that this general behavior is characteristic of all boundary-value problems of this type, independently of whether $\Phi(x, 0)$ is a constant or not, provided the first term in the series is nonvanishing. The

coefficient A_1 (2.60) will be different, but the smooth behavior in x of the asymptotic solution sets in for $y \geq a$, regardless of the complexities of $\Phi(x, 0)$. This is shown quantitatively for the present example in Fig. 2.11 where the potential along the two dashed lines, $y/a = 0.1, 0.5$, of Fig. 2.10 is plotted. The solid curves are the exact potential, the dotted, the first term (2.62). Close to the boundary ($y/a = 0.1$) the curves differ appreciably, but for $y/a = 0.5$ the asymptotic form is already an excellent approximation.

There are many Fourier series that can be summed to give an answer in closed form. The series in (2.61) is one of them. We proceed as follows. Observing that $\sin \theta = \text{Im}(e^{i\theta})$, where Im stands for the imaginary part, we see that (2.61) can be written as

$$\Phi(x, y) = \frac{4V}{\pi} \text{Im} \sum_{n \text{ odd}} \frac{1}{n} e^{(in\pi/a)(x+iy)}$$

Fig. 2.11 Potentials at $y/a = 0.1, 0.5$ (along the dashed lines of Fig. 2.10) as functions of x/a . The solid curves are the exact solution; the dashed curves are the first term in the series solution (2.61).

With the definition,

$$Z = e^{(i\pi/a)(x+iy)} \quad (2.63)$$

this can be put in the suggestive form,

$$\Phi(x, y) = \frac{4V}{\pi} \operatorname{Im} \sum_{n \text{ odd}} \frac{Z^n}{n}$$

At this point we can perhaps recall the expansion,*

$$\ln(1+Z) = Z - \frac{1}{2}Z^2 + \frac{1}{3}Z^3 - \frac{1}{4}Z^4 + \dots$$

Evidently,

$$\sum_{n \text{ odd}} \frac{Z^n}{n} = \frac{1}{2} \ln \left(\frac{1+Z}{1-Z} \right)$$

and

$$\Phi(x, y) = \frac{2V}{\pi} \operatorname{Im} \left[\ln \left(\frac{1+Z}{1-Z} \right) \right] \quad (2.64)$$

Since the imaginary part of a logarithm is equal to the phase of its argument, we consider

$$\frac{1+Z}{1-Z} = \frac{(1+Z)(1-Z^*)}{|1-Z|^2} = \frac{1-|Z|^2 + 2i \operatorname{Im} Z}{|1-Z|^2}.$$

The phase of the argument of the logarithm is thus $\tan^{-1} [2 \operatorname{Im} Z / (1-|Z|^2)]$. With the explicit form (2.63) of Z substituted, it is found that the potential becomes

$$\Phi(x, y) = \frac{2V}{\pi} \tan^{-1} \left(\frac{\sin \frac{\pi x}{a}}{\sinh \frac{\pi y}{a}} \right) \quad (2.65)$$

The branch of the tangent curve corresponds to the angle lying between 0 and $\pi/2$. The infinite series (2.61) has been transformed into the explicit closed form (2.65). The reader may verify that the boundary conditions are satisfied and that the asymptotic form (2.62) emerges in a simple manner.

The potential (2.64) with Z given by (2.63) is obviously related to functions of a complex variable. This connection is a direct consequence of the fact that the real or the imaginary part of an analytic function satisfies the Laplace equation in two dimensions as a result of the Cauchy-Riemann equations. As already mentioned at the beginning of the chapter, we omit discussion of the complex-variable technique, not because it is unimportant but for lack of space and because completely adequate discussions exist elsewhere. Some of these sources are listed at the end of the chapter. The methods of summation of Fourier series, with many examples, are described in *Collin*, Appendix A.6.

* Alternatively, we observe that $(d/dZ) \left(\sum_{n=1}^{\infty} (Z^n/n) \right) = \sum_{n=0}^{\infty} Z^n = 1/(1-Z)$. Integration then gives $\sum_{n=1}^{\infty} (Z^n/n) = -\ln(1-Z)$.

2.11 Fields and Charge Densities in Two-Dimensional Corners and Along Edges

In many practical situations conducting surfaces come together in a way that can be approximated, on the small scale at least, as the intersection of two planes. The edges of the box shown in Fig. 2.9 are one example, the corners at $x=0$, $y=0$ and $x=a$, $y=0$ in Fig. 2.10 another. It is useful therefore to have an understanding of how the potential, the fields, and the surface charge densities behave in the neighborhood of such sharp “corners” or edges. We shall assume that they are infinitely sharp so that we can look at them closely enough that the behavior of the fields is determined in functional form solely by the properties of the “corner” being considered and not by the details of the overall configuration.

The general situation in two dimensions is shown in Fig. 2.12. Two conducting planes intersect at an angle β . The planes are assumed to be held at potential V . Remote from the origin and not shown in the figure are other conductors or possibly configurations of charges that specify the potential problem uniquely. Since we are interested in the functional behavior of the fields, etc. near the origin, but not in the absolute magnitudes, we leave the “far away” behavior unspecified as much as possible.

The geometry of Fig. 2.12 suggests use of polar rather than Cartesian coordinates. In terms of the polar coordinates (ρ, ϕ) , the Laplace equation in two dimensions is

$$\frac{1}{\rho} \frac{\partial}{\partial \rho} \left(\rho \frac{\partial \Phi}{\partial \rho} \right) + \frac{1}{\rho^2} \frac{\partial^2 \Phi}{\partial \phi^2} = 0 \quad (2.66)$$

Using the separation of variables approach, we substitute

$$\Phi(\rho, \phi) = R(\rho)\Psi(\phi)$$

Fig. 2.12 Intersection of two conducting planes defining a corner in two dimensions with opening angle β .

This leads, upon multiplication by ρ^2/Φ , to

$$\frac{\rho}{R} \frac{d}{d\rho} \left(\rho \frac{dR}{d\rho} \right) + \frac{1}{\Psi} \frac{d^2\Psi}{d\phi^2} = 0 \quad (2.67)$$

Since the two terms are separately functions of ρ and ϕ , respectively, they each must be constant:

$$\frac{\rho}{R} \frac{d}{d\rho} \left(\rho \frac{dR}{d\rho} \right) = \nu^2, \quad \frac{1}{\Psi} \frac{d^2\Psi}{d\phi^2} = -\nu^2 \quad (2.68)$$

The solutions to these equations are

$$\left. \begin{aligned} R(\rho) &= a\rho^\nu + b\rho^{-\nu} \\ \Psi(\phi) &= A \cos(\nu\phi) + B \sin(\nu\phi) \end{aligned} \right\} \quad (2.69)$$

For the special circumstance of $\nu=0$, the solutions are

$$\left. \begin{aligned} R(\rho) &= a_0 + b_0 \ln \rho \\ \Psi(\phi) &= A_0 + B_0 \phi \end{aligned} \right\} \quad (2.70)$$

These are the building blocks with which we construct the potential by linear superposition.

Although not central to our present purpose, we note the general solution of the Laplace equation in two dimensions when the full azimuthal range is permitted as, for example, for the potential between two cylindrical surfaces, $\rho=a$ and $\rho=b$, on which the potential is given as a function of ϕ . If there is no restriction on ϕ , it is necessary that ν be a positive or negative integer or zero in order that the potential be single-valued. Furthermore, for $\nu=0$, the constant B_0 in (2.70) must vanish for the same reason. The general solution is therefore of the form,

$$\Phi(\rho, \phi) = a_0 + b_0 \ln \rho + \sum_{n=1}^{\infty} a_n \rho^n \sin(n\phi + \alpha_n) + \sum_{n=1}^{\infty} b_n \rho^{-n} \sin(n\phi + \beta_n) \quad (2.71)$$

If the origin is included in the volume in which there is no charge, all the b_n are zero. Only a constant and positive powers of ρ appear. If the origin is excluded, the b_n can be different from zero. In particular, the logarithmic term is equivalent to a line charge on the axis with charge density per unit length $\lambda = -b_0/2$, as is well known.

For the situation of Fig. 2.12 the azimuthal angle is restricted to the range, $0 \leq \phi \leq \beta$. The boundary conditions are that $\Phi = V$ for all $\rho \geq 0$ when $\phi=0$ and $\phi=\beta$. This requires that $b_0 = B_0 = 0$ in (2.70) and $b=0$ and $A=0$ in (2.69). Furthermore, it requires that ν be chosen to make $\sin(\nu\beta) = 0$. Hence

$$\nu = \frac{m\pi}{\beta}, \quad m = 1, 2, \dots$$

and the general solution becomes

$$\Phi(\rho, \phi) = V + \sum_{m=1}^{\infty} a_m \rho^{m\pi/\beta} \sin(m\pi\phi/\beta) \quad (2.72)$$

The still undetermined coefficients a_m depend on the potential remote from the corner at $\rho=0$. Since the series involves positive powers of $\rho^{\pi/\beta}$, for small enough ρ only the first term in the series will be important.* Thus, near $\rho=0$, the potential is approximately

$$\Phi(\rho, \phi) \approx V + a_1 \rho^{\pi/\beta} \sin(\pi\phi/\beta) \quad (2.73)$$

The electric field components are

$$\left. \begin{aligned} E_\rho(\rho, \phi) &= -\frac{\partial\Phi}{\partial\rho} \approx -\frac{\pi a_1}{\beta} \rho^{(\pi/\beta)-1} \sin(\pi\phi/\beta) \\ E_\phi(\rho, \phi) &= -\frac{1}{\rho} \frac{\partial\Phi}{\partial\phi} \approx -\frac{\pi a_1}{\beta} \rho^{(\pi/\beta)-1} \cos(\pi\phi/\beta) \end{aligned} \right\} \quad (2.74)$$

The surface charge densities at $\phi=0$ and $\phi=\beta$ are equal and are approximately

$$\sigma(\rho) = \frac{E_\phi(\rho, 0)}{4\pi} \approx -\frac{a_1}{4\beta} \rho^{(\pi/\beta)-1} \quad (2.75)$$

The components of the field and the surface charge density near $\rho=0$ all vary with distance as $\rho^{(\pi/\beta)-1}$. This dependence on ρ is shown for some special cases in

Fig. 2.13 Variation of the surface charge density (and the electric field) with distance ρ from the "corner" or edge for opening angles $\beta = \pi/4, \pi/2, \pi, 3\pi/2$, and 2π .

Fig. 2.13. For a very deep corner (small β) the power of ρ becomes very large. Essentially no charge accumulates in such a corner. For $\beta = \pi$ (a flat surface), the field quantities become independent of ρ , as is intuitively obvious. When $\beta > \pi$, the two-dimensional corner becomes an edge and the field and the surface

* Here we make a necessary assumption about the remote boundary conditions, namely, that they are such that the coefficient a_1 is not zero. Ordinarily this is no concern, but special symmetries might make a_1 or even a_2 , etc. vanish. These unusual examples must be treated separately.

charge density become singular as $\rho \rightarrow 0$. For $\beta = 2\pi$ (the edge of a thin sheet) the singularity is as $\rho^{-1/2}$. This is still integrable so that the charge within a finite distance from the edge is finite, but it implies that field strengths become very large at the edges of conducting sheets (or, in fact, for any configuration where $\beta > \pi$).

The above two-dimensional electrostatic considerations apply to many three-dimensional situations, even with time-varying fields. If the edge is a sharp edge of finite length, as the edge of a cube away from a corner, then sufficiently close to the edge the variation of the potential along the edge can be ignored. The two-dimensional considerations apply, although the coefficient a_1 in (2.75) may vary with distance along the edge. Similarly, the electrostatic arguments are valid even for time-varying fields. The point here is that with time dependence another length enters, namely, the wavelength. Provided one is concerned with distances away from the edge that are small compared to a wavelength, as well as other relevant distances, the behavior of the fields reduces to electrostatic or magnetostatic behavior. In the diffraction of microwaves by a hole in a thin conducting sheet, for example, the fields are singular as $\rho^{-1/2}$ as $\rho \rightarrow 0$, where ρ is the distance from the boundary of the hole, and this fact must be taken into account in any exact solution of the diffraction problem.

The singular behavior of the fields near sharp edges is the reason for the effectiveness of lightning rods. In the idealized situation discussed here the field strength increases without limit as $\rho \rightarrow 0$, but for a thin sheet of thickness d with a smoothly rounded edge it can be inferred that the field strength at the surface will be proportional to $d^{-1/2}$. For small enough d this can be very large. In absolute vacuum such field strengths are possible, but in air electrical breakdown and a discharge will occur if the field strength exceeds a certain value (depending on the exact shape of the electrode, its proximity to the other electrodes, etc., but greater than about 2.5×10^4 volts/cm for air at N.T.P., sometimes by a factor of four). In thunderstorms, with large potential differences between the ground and the thunderclouds, a grounded sharp conducting edge, or better, a point (see Section 3.4), will have breakdown occur around it first and will then provide one end of the jagged conducting path through the air along which the lightning discharge travels.

Gibbs,

Rothe, Ollendorff, and Polhausen.

Elementary, but clear, discussions of the mathematical theory of Fourier series and integrals, and orthogonal expansions, can be found in

Churchill,

Hildebrand, Chapter 5.

A somewhat old-fashioned treatment of Fourier series and integrals, but with many examples and problems, is given by

Byerly.

PROBLEMS

2.1 A point charge q is brought to a position a distance d away from an infinite plane conductor held at zero potential. Using the method of images, find:

- the surface-charge density induced on the plane, and plot it;
- the force between the plane and the charge by using Coulomb's law for the force between the charge and its image;
- the total force acting on the plane by integrating $2\pi\sigma^2$ over the whole plane;
- the work necessary to remove the charge q from its position to infinity;
- the potential energy between the charge q and its image [compare the answer to (d) and discuss].
- Find answer (d) in electron volts for an electron originally one angstrom from the surface.

2.2 Using the method of images, discuss the problem of a point charge q inside a hollow, grounded, conducting sphere of inner radius a . Find

- the potential inside the sphere;
- the induced surface-charge density;
- the magnitude and direction of the force acting on q .

Is there any change in the solution if the sphere is kept at a fixed potential V ? If the sphere has a total charge Q on its inner and outer surfaces?

2.3 Consider a potential problem in the half-space defined by $z \geq 0$, with Dirichlet boundary conditions on the plane $z = 0$ (and at infinity).

- (a) Write down the appropriate Green function $G(\mathbf{x}, \mathbf{x}')$.
 (b) If the potential on the plane $z=0$ is specified to be $\Phi = V$ inside a circle of radius a centered at the origin, and $\Phi = 0$ outside that circle, find an integral expression for the potential at the point P specified in terms of cylindrical coordinates (ρ, ϕ, z) .
 (c) Show that, along the axis of the circle ($\rho = 0$), the potential is given by

$$\Phi = V \left(1 - \frac{z}{\sqrt{a^2 + z^2}} \right)$$

- (d) Show that at large distances ($\rho^2 + z^2 \gg a^2$) the potential can be expanded in a power series in $(\rho^2 + z^2)^{-1}$, and that the leading terms are

$$\Phi = \frac{Va^2}{2} \frac{z}{(\rho^2 + z^2)^{3/2}} \left[1 - \frac{3a^2}{4(\rho^2 + z^2)} + \frac{5(3\rho^2 a^2 + a^4)}{8(\rho^2 + z^2)^2} + \dots \right]$$

Verify that the results of (c) and (d) are consistent with each other in their common range of validity.

- 2.4** A two-dimensional potential problem is defined by two straight parallel line charges separated by a distance R with equal and opposite linear charge densities λ and $-\lambda$.

(a) Show by direct construction that the surface of constant potential V is a circular cylinder (circle in the transverse dimensions) and find the coordinates of the axis of the cylinder and its radius in terms of R , λ , and V .

(b) Use the results of (a) to show that the capacitance per unit length C of two right-circular cylindrical conductors, with radii a and b , separated by a distance $d > a + b$, is

$$C = \frac{1}{2 \cosh^{-1} \left(\frac{d^2 - a^2 - b^2}{2ab} \right)}$$

(c) Verify that the result for C agrees with the answer in Problem 1.7 in the appropriate limit and determine the next nonvanishing order correction in powers of a/d and b/d .

(d) Repeat the calculation of the capacitance per unit length for two cylinders inside each other ($d < |b - a|$). Check the result for concentric cylinders ($d = 0$).

- 2.5** An insulated, spherical, conducting shell of radius a is in a uniform electric field E_0 . If the sphere is cut into two hemispheres by a plane perpendicular to the field, find the force required to prevent the hemispheres from separating

- (a) if the shell is uncharged;
 (b) if the total charge on the shell is Q .

- 2.6** A large parallel plate capacitor is made up of two plane conducting sheets, one of which has a small hemispherical boss of radius a on its inner surface. The conductor with the boss is kept at zero potential, and the other conductor is at a potential such that far from the boss the electric field between the plates is E_0 .

- (a) Calculate the surface-charge densities at an arbitrary point on the plane and on the boss, and sketch their behavior as a function of distance (or angle).
 (b) Show that the total charge on the boss has the magnitude $3E_0 a^2/4$.
 (c) If, instead of the other conducting sheet at a different potential, a point charge q is placed directly above the hemispherical boss at a distance d from its center, show that

the charge induced on the boss is

$$q' = -q \left[1 - \frac{d^2 - a^2}{d\sqrt{d^2 + a^2}} \right]$$

- 2.7** A line charge with linear charge density τ is placed parallel to, and a distance R away from, the axis of a conducting cylinder of radius b held at fixed voltage such that the potential vanishes at infinity. Find
- the magnitude and position of the image charge(s);
 - The potential at any point (expressed in polar coordinates with the origin at the axis of the cylinder and the direction from the origin to the line charge as the x axis), including the asymptotic form far from the cylinder;
 - the induced surface-charge density, and plot it as a function of angle for $R/b = 2, 4$ in units of $\tau/2\pi b$;
 - the force on the charge.

- 2.8** Starting with the series solution (2.71) for the two-dimensional potential problem with the potential specified on the surface of a cylinder of radius b , evaluate the coefficients formally, substitute them into the series, and sum it to obtain the potential inside the cylinder in the form of Poisson's integral:

$$\Phi(\rho, \phi) = \frac{1}{2\pi} \int_0^{2\pi} \Phi(b, \phi') \frac{b^2 - \rho^2}{b^2 + \rho^2 - 2b\rho \cos(\phi' - \phi)} d\phi'$$

What modification is necessary if the potential is desired in the region of space bounded by the cylinder and infinity?

- 2.9** (a) Two halves of a long hollow conducting cylinder of inner radius b are separated by small lengthwise gaps on each side, and are kept at different potentials V_1 and V_2 . Show that the potential inside is given by

$$\Phi(\rho, \phi) = \frac{V_1 + V_2}{2} + \frac{V_1 - V_2}{\pi} \tan^{-1} \left(\frac{2b\rho}{b^2 - \rho^2} \cos \phi \right)$$

where ϕ is measured from a plane perpendicular to the plane through the gap.

(b) Calculate the surface-charge density on each half of the cylinder.

- 2.10** A variant of the previous two-dimensional problem is a long hollow conducting cylinder of radius b that is divided into equal quarters, alternate segments being held at potential $+V$ and $-V$.

(a) Solve by means of the series solution (2.71) and show that the potential inside the cylinder is

$$\Phi(\rho, \phi) = \frac{4V}{\pi} \sum_{n=0}^{\infty} \left(\frac{\rho}{b} \right)^{4n+2} \frac{\sin[(4n+2)\phi]}{2n+1}$$

(b) Sum the series and show that

$$\Phi(\rho, \phi) = \frac{2V}{\pi} \tan^{-1} \left(\frac{2\rho^2 b^2 \sin 2\phi}{b^4 - \rho^4} \right)$$

(c) Sketch the field lines and equipotentials.

- 2.11 (a) Use the method of images to show that the two-dimensional Dirichlet Green function for the exterior problem of a cylinder of radius b is

$$G(\rho, \phi; \rho', \phi') = \ln \left\{ \frac{b^4 + \rho^2 \rho'^2 - 2b^2 \rho \rho' \cos(\phi - \phi')}{b^2 [\rho^2 + \rho'^2 - 2\rho \rho' \cos(\phi - \phi')]} \right\} \\ = \ln \left[\frac{(\rho^2 - b^2)(\rho'^2 - b^2) + b^2 |\boldsymbol{\rho} - \boldsymbol{\rho}'|^2}{b^2 |\boldsymbol{\rho} - \boldsymbol{\rho}'|^2} \right]$$

where $\boldsymbol{\rho}$ and $\boldsymbol{\rho}'$ are coordinate vectors in the plane.

- (b) Use this Green function to verify the result of Problem 1.7.
 (c) What modifications, if any, are needed for the interior problem?
- 2.12 (a) Use the Green function of Problem 2.11 and the solution (1.44) to obtain the Poisson integral form of the solution (Problem 2.8) for the Dirichlet problem in a circle.
 (b) Use Cauchy's theorem to derive the Poisson integral solution. Cauchy's theorem states that if $F(z)$ is analytic in a region R bounded by a closed curve C , then

$$\frac{1}{2\pi i} \oint_C \frac{F(z') dz'}{z' - z} = \begin{cases} F(z) & \text{if } z \text{ is inside } R \\ 0 & \text{if } z \text{ is outside } R \end{cases}$$

Hint: You may wish to add an integral that vanishes (associated with the image point) to the integral for the point inside the circle.

- 2.13 A hollow cube has conducting walls defined by six planes $x=0$, $y=0$, $z=0$, and $x=a$, $y=a$, $z=a$. The walls $z=0$ and $z=a$ are held at a constant potential V . The other four sides are at zero potential.
 (a) Find the potential $\Phi(x, y, z)$ at any point inside the cube.
 (b) Evaluate the potential at the center of the cube numerically, accurate to three significant figures. How many terms in the series is it necessary to keep in order to attain this accuracy? Compare your numerical result with the average value of the potential on the walls. See Problem 2.16.
 (c) Find the surface-charge density on the surface $z=a$.

- 2.14 The two-dimensional region, $\rho \geq a$, $0 \leq \phi \leq \beta$, is bounded by conducting surfaces at $\phi=0$, $\rho=a$, and $\phi=\beta$ held at zero potential, as indicated in the sketch. At large ρ the potential is determined by some configuration of charges and/or conductors at fixed potentials.

Problem 2.14

(a) Write down a solution for the potential $\Phi(\rho, \phi)$ that satisfies the boundary conditions for finite ρ .

(b) Keeping only the lowest nonvanishing terms, calculate the electric field components E_ρ and E_ϕ and also the surface charge densities $\sigma(\rho, 0)$, $\sigma(\rho, \beta)$, and $\sigma(a, \phi)$ on the three boundary surfaces.

(c) Consider $\beta = \pi$ (a plane conductor with a half-cylinder of radius a on it). Show that far from the half-cylinder the lowest order terms of (b) give a uniform electric field normal to the plane. Sketch the charge density on and in the neighborhood of the half-cylinder. For fixed electric field strength far from the plane, show that the total charge on the half-cylinder (actually charge per unit length in the z direction) is twice as large as would reside on a strip of width $2a$ in its absence. Show that the extra portion is drawn from regions of the plane nearby, so that the total charge on a strip of width large compared to a is the same whether the half-cylinder is there or not.

2.15 Consider the two-dimensional wedge-shaped region of Problem 2.14, with $\beta = 2\pi$. This corresponds to a semiinfinite thin sheet of conductor on the positive x axis from $x = a$ to infinity with a conducting cylinder of radius a fastened to its edge.

(a) Sketch the surface charge densities on the cylinder and on the top and bottom of the sheet, using the lowest order solution.

(b) Calculate the total charge on the cylinder and compare with the total deficiency of charge on the sheet near the cylinder, that is, the total difference in charge for a finite compared with $a = 0$, assuming that the charge density far from the cylinder is the same.

2.16 A closed volume is bounded by conducting surfaces that are the n sides of a regular polyhedron ($n = 4, 6, 8, 12, 20$). The n surfaces are at different potentials V_i , $i = 1, 2, \dots, n$. Prove in the simplest way you can that the potential at the center of the polyhedron is the average of the potential on the n sides. This problem bears on Problem 2.13(b), and has an interesting similarity to the result of Problem 1.10.

3

Boundary-Value Problems in Electrostatics: II

In this chapter the discussion of boundary-value problems is continued. Spherical and cylindrical geometries are first considered, and solutions of the Laplace equation are represented by expansions in series of the appropriate orthonormal functions. Only an outline is given of the solution of the various ordinary differential equations obtained from the Laplace equation by separation of variables, but an adequate summary of the properties of the different functions is presented.

The problem of construction of Green functions in terms of orthonormal functions arises naturally in the attempt to solve the Poisson equation in the various geometries. Explicit examples of Green functions are obtained and applied to specific problems, and the equivalence of the various approaches to potential problems is discussed.

3.1 Laplace Equation in Spherical Coordinates

In spherical coordinates (r, θ, ϕ) , shown in Fig. 3.1, the Laplace equation can be written in the form:

$$\frac{1}{r} \frac{\partial^2}{\partial r^2} (r\Phi) + \frac{1}{r^2 \sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial \Phi}{\partial \theta} \right) + \frac{1}{r^2 \sin^2 \theta} \frac{\partial^2 \Phi}{\partial \phi^2} = 0 \quad (3.1)$$

If a product form for the potential is assumed, then it can be written:

$$\Phi = \frac{U(r)}{r} P(\theta) Q(\phi) \quad (3.2)$$

When this is substituted into (3.1), there results the equation:

$$PQ \frac{d^2 U}{dr^2} + \frac{UQ}{r^2 \sin \theta} \frac{d}{d\theta} \left(\sin \theta \frac{dP}{d\theta} \right) + \frac{UP}{r^2 \sin^2 \theta} \frac{d^2 Q}{d\phi^2} = 0$$

Fig. 3.1

If we multiply by $r^2 \sin^2 \theta / UPQ$, we obtain:

$$r^2 \sin^2 \theta \left[\frac{1}{U} \frac{d^2 U}{dr^2} + \frac{1}{r^2 \sin \theta P} \frac{d}{d\theta} \left(\sin \theta \frac{dP}{d\theta} \right) \right] + \frac{1}{Q} \frac{d^2 Q}{d\phi^2} = 0 \quad (3.3)$$

The ϕ dependence of the equation has now been isolated in the last term. Consequently that term must be a constant which we call $(-m^2)$:

$$\frac{1}{Q} \frac{d^2 Q}{d\phi^2} = -m^2 \quad (3.4)$$

This has solutions

$$Q = e^{\pm im\phi} \quad (3.5)$$

In order that Q be single valued, m must be an integer if the full azimuthal range is allowed. By similar considerations we find separate equations for $P(\theta)$ and $U(r)$:

$$\frac{1}{\sin \theta} \frac{d}{d\theta} \left(\sin \theta \frac{dP}{d\theta} \right) + \left[l(l+1) - \frac{m^2}{\sin^2 \theta} \right] P = 0 \quad (3.6)$$

$$\frac{d^2 U}{dr^2} - \frac{l(l+1)}{r^2} U = 0 \quad (3.7)$$

where $l(l+1)$ is another real constant.

From the form of the radial equation it is apparent that a single power of r (rather than a power series) will satisfy it. The solution is found to be:

$$U = Ar^{l+1} + Br^{-l} \quad (3.8)$$

but l is as yet undetermined.

3.2 Legendre Equation and Legendre Polynomials

The θ equation for $P(\theta)$ is customarily expressed in terms of $x = \cos \theta$, instead of θ itself. Then it takes the form:

$$\frac{d}{dx} \left[(1-x^2) \frac{dP}{dx} \right] + \left[l(l+1) - \frac{m^2}{1-x^2} \right] P = 0 \quad (3.9)$$

This equation is called the generalized Legendre equation, and its solutions are the associated Legendre functions. Before considering (3.9) we will outline the solution by power series of the ordinary Legendre differential equation with $m^2=0$;

$$\frac{d}{dx} \left[(1-x^2) \frac{dP}{dx} \right] + l(l+1)P = 0 \quad (3.10)$$

We assume that the whole range of $\cos \theta$, including the north and south poles, is in the region of interest. The desired solution should then be single valued, finite, and continuous on the interval $-1 \leq x \leq 1$ in order that it represents a physical potential. The solution will be assumed to be represented by a power series of the form:

$$P(x) = x^\alpha \sum_{j=0}^{\infty} a_j x^j \quad (3.11)$$

where α is a parameter to be determined. When this is substituted into (3.10), there results the series:

$$\sum_{j=0}^{\infty} \{ (\alpha+j)(\alpha+j-1)a_j x^{\alpha+j-2} - [(\alpha+j)(\alpha+j+1) - l(l+1)]a_j x^{\alpha+j} \} = 0 \quad (3.12)$$

In this expansion the coefficient of each power of x must vanish separately. For $j=0, 1$ we find that

$$\begin{aligned} \text{if } a_0 \neq 0, & \quad \text{then } \alpha(\alpha-1) = 0 \\ \text{if } a_1 \neq 0, & \quad \text{then } \alpha(\alpha+1) = 0 \end{aligned} \quad (3.13)$$

while for a general j value

$$a_{j+2} = \left[\frac{(\alpha+j)(\alpha+j+1) - l(l+1)}{(\alpha+j+1)(\alpha+j+2)} \right] a_j \quad (3.14)$$

A moment's thought shows that the two relations (3.13) are equivalent and that is is sufficient to choose *either* a_0 or a_1 different from zero, but not both. Making the former choice, we have $\alpha=0$ or $\alpha=1$. From (3.14) we see that the power series has only even powers of x ($\alpha=0$) or only odd powers of x ($\alpha=1$).

For either of the series $\alpha=0$ or $\alpha=1$ it is possible to prove the following properties:

- (a) the series converges for $x^2 < 1$, regardless of the value of l ;
- (b) the series diverges at $x = \pm 1$, unless it terminates.

Since we want a solution that is finite at $x = \pm 1$, as well as for $x^2 < 1$, we demand that the series terminate. Since α and j are positive integers or zero, the recurrence relation (3.14) will terminate only if l is zero or a positive integer. Even then only one of the two series converges at $x = \pm 1$. If l is even (odd), then only

the $\alpha = 0$ ($\alpha = 1$) series terminates.* The polynomials in each case have x^l as their highest power of x , the next highest being x^{l-2} , and so on, down to $x^0(x)$ for l even (odd). By convention these polynomials are normalized to have the value unity at $x = +1$ and are called the *Legendre polynomials* of order l , $P_l(x)$. The first few Legendre polynomials are:

$$\left. \begin{aligned} P_0(x) &= 1 \\ P_1(x) &= x \\ P_2(x) &= \frac{1}{2}(3x^2 - 1) \\ P_3(x) &= \frac{1}{2}(5x^3 - 3x) \\ P_4(x) &= \frac{1}{8}(35x^4 - 30x^2 + 3) \end{aligned} \right\} \quad (3.15)$$

By manipulation of the power series solutions (3.11) and (3.14) it is possible to obtain a compact representation of the Legendre polynomials, known as *Rodrigues' formula*:

$$P_l(x) = \frac{1}{2^l l!} \frac{d^l}{dx^l} (x^2 - 1)^l \quad (3.16)$$

[This can be obtained by other, more elegant means, or by direct l -fold integration of the differential equation (3.10).]

The Legendre polynomials form a complete orthogonal set of functions on the interval $-1 \leq x \leq 1$. To prove the orthogonality we can appeal directly to the differential equation (3.10). We write down the differential equation for $P_l(x)$, multiply by $P_{l'}(x)$, and then integrate over the interval:

$$\int_{-1}^1 P_{l'}(x) \left\{ \frac{d}{dx} \left[(1-x^2) \frac{dP_l}{dx} \right] + l(l+1)P_l(x) \right\} dx = 0 \quad (3.17)$$

Integrating the first term by parts, we obtain

$$\int_{-1}^1 \left[(x^2 - 1) \frac{dP_l}{dx} \frac{dP_{l'}}{dx} + l(l+1)P_{l'}(x)P_l(x) \right] dx = 0 \quad (3.18)$$

If we now write down (3.18) with l and l' interchanged and subtract it from (3.18), the result is the orthogonality condition:

$$[l(l+1) - l'(l'+1)] \int_{-1}^1 P_{l'}(x)P_l(x) dx = 0 \quad (3.19)$$

* For example, if $l=0$ the $\alpha=1$ series has a general coefficient $a_j = a_0/j + 1$ for $j=0, 2, 4, \dots$. Thus the series is $a_0(x + \frac{1}{3}x^3 + \frac{1}{5}x^5 + \dots)$. This is just the power series expansion of a function $Q_0(x) = \frac{1}{2} \ln \left(\frac{1+x}{1-x} \right)$, which clearly diverges at $x = \pm 1$. For each l value there is a similar function $Q_l(x)$ with logarithms in it as the partner to the well-behaved polynomial solution. See *Magnus and Oberhettinger*, p. 59 ff or *Magnus, Oberhettinger and Soni*, pp. 151 ff. *Whittaker and Watson*, Chapter XV, give a treatment using analytic functions.

For $l \neq l'$, the integral must vanish. For $l = l'$, the integral is finite. To determine its value it is necessary to use an explicit representation of the Legendre polynomials, e.g., Rodrigues' formula. Then the integral is explicitly:

$$N_l \equiv \int_{-1}^1 [P_l(x)]^2 dx = \frac{1}{2^{2l}(l!)^2} \int_{-1}^1 \frac{d^l}{dx^l} (x^2-1)^l \frac{d^l}{dx^l} (x^2-1)^l dx$$

Integration by parts l times yields the result:

$$N_l = \frac{(-1)^l}{2^{2l}(l!)^2} \int_{-1}^1 (x^2-1)^l \frac{d^{2l}}{dx^{2l}} (x^2-1)^l dx$$

The differentiation of $(x^2-1)^l$ $2l$ times yields the constant $(2l)!$, so that

$$N_l = \frac{(2l)!}{2^{2l}(l!)^2} \int_{-1}^1 (1-x^2)^l dx$$

The remaining integral can be done by brute force, but also by induction. We write the integrand as

$$(1-x^2)^l = (1-x^2)(1-x^2)^{l-1} = (1-x^2)^{l-1} + \frac{x}{2l} \frac{d}{dx} (1-x^2)^l$$

Thus we have

$$N_l = \left(\frac{2l-1}{2l} \right) N_{l-1} + \frac{(2l-1)!}{2^{2l}(l!)^2} \int_{-1}^1 x d[(1-x^2)^l]$$

Integration by parts in the last integral yields

$$N_l = \left(\frac{2l-1}{2l} \right) N_{l-1} - \frac{1}{2l} N_l$$

or

$$(2l+1)N_l = (2l-1)N_{l-1} \quad (3.20)$$

This shows that $(2l+1)N_l$ is independent of l . For $l=0$, with $P_0(x)=1$, we have $N_0=2$. Thus $N_l = 2/(2l+1)$ and the orthogonality condition can be written:

$$\int_{-1}^1 P_l(x) P_l(x) dx = \frac{2}{2l+1} \delta_{ll} \quad (3.21)$$

and the orthonormal functions in the sense of Section 2.8 are

$$U_l(x) = \sqrt{\frac{2l+1}{2}} P_l(x) \quad (3.22)$$

Since the Legendre polynomials form a complete set of orthogonal functions, any function $f(x)$ on the interval $-1 \leq x \leq 1$ can be expanded in terms of them. The Legendre series representation is:

$$f(x) = \sum_{l=0}^{\infty} A_l P_l(x) \quad (3.23)$$

Fig. 3.2

where

$$A_l = \frac{2l+1}{2} \int_{-1}^1 f(x) P_l(x) dx \quad (3.24)$$

As an example, consider the function shown in Fig. 3.2:

$$\begin{aligned} f(x) &= +1 & \text{for } x > 0 \\ &= -1 & \text{for } x < 0 \end{aligned}$$

Then

$$A_l = \frac{2l+1}{2} \left[\int_0^1 P_l(x) dx - \int_{-1}^0 P_l(x) dx \right]$$

Since $P_l(x)$ is odd (even) about $x=0$ if l is odd (even), only the odd l coefficients are different from zero. Thus, for l odd,

$$A_l = (2l+1) \int_0^1 P_l(x) dx \quad (3.25)$$

By means of Rodrigues' formula the integral can be evaluated, yielding

$$A_l = \left(-\frac{1}{2}\right)^{(l-1)/2} \frac{(2l+1)(l-2)!!}{2\left(\frac{l+1}{2}\right)!} \quad (3.26)$$

where $(2n+1)!! \equiv (2n+1)(2n-1)(2n-3) \cdots \times 5 \times 3 \times 1$. Thus the series for $f(x)$ is:

$$f(x) = \frac{3}{2}P_1(x) - \frac{7}{8}P_3(x) + \frac{11}{16}P_5(x) - \cdots \quad (3.27)$$

Certain recurrence relations among Legendre polynomials of different order are useful in evaluating integrals, generating higher-order polynomials from lower-order ones, etc. From Rodrigues' formula it is a straightforward matter to show that

$$\frac{dP_{l+1}}{dx} - \frac{dP_{l-1}}{dx} - (2l+1)P_l = 0 \quad (3.28)$$

This result, combined with differential equation (3.10), can be made to yield

various recurrence formulas, some of which are:

$$\left. \begin{aligned} (l+1)P_{l+1} - (2l+1)xP_l + lP_{l-1} &= 0 \\ \frac{dP_{l+1}}{dx} - x\frac{dP_l}{dx} - (l+1)P_l &= 0 \\ (x^2-1)\frac{dP_l}{dx} - lxP_l + lP_{l-1} &= 0 \end{aligned} \right\} \quad (3.29)$$

As an illustration of the use of these recurrence formulas consider the evaluation of the integral:

$$I_1 = \int_{-1}^1 xP_l(x)P_{l'}(x) dx \quad (3.30)$$

From the first of the recurrence formulas (3.29) we obtain an expression for $xP_l(x)$. Therefore (3.30) becomes

$$I_1 = \frac{1}{2l+1} \int_{-1}^1 P_{l'}(x)[(l+1)P_{l+1}(x) + lP_{l-1}(x)] dx$$

The orthogonality integral (3.21) can now be employed to show that the integral vanishes unless $l' = l \pm 1$, and that, for those values,

$$\int_{-1}^1 xP_l(x)P_{l'}(x) dx = \begin{cases} \frac{2(l+1)}{(2l+1)(2l+3)}, & l' = l+1 \\ \frac{2l}{(2l-1)(2l+1)}, & l' = l-1 \end{cases} \quad (3.31)$$

These are really the same result with the roles of l and l' interchanged. In a similar manner it is easy to show that

$$\int_{-1}^1 x^2 P_l(x)P_{l'}(x) dx = \begin{cases} \frac{2(l+1)(l+2)}{(2l+1)(2l+3)(2l+5)}, & l' = l+2 \\ \frac{2(2l^2+2l-1)}{(2l-1)(2l+1)(2l+3)}, & l' = l \end{cases} \quad (3.32)$$

where it is assumed that $l' \geq l$.

3.3 Boundary-Value Problems with Azimuthal Symmetry

From the form of the solution of the Laplace equation in spherical coordinates (3.2) it will be seen that, for a problem possessing azimuthal symmetry, $m=0$ in (3.5). This means that the general solution for such a problem is:

$$\Phi(r, \theta) = \sum_{l=0}^{\infty} [A_l r^l + B_l r^{-(l+1)}] P_l(\cos \theta) \quad (3.33)$$

The coefficients A_l and B_l can be determined from the boundary conditions. Suppose that the potential is specified to be $V(\theta)$ on the surface of a sphere of radius a , and it is required to find the potential inside the sphere. If there are no charges at the origin, the potential must be finite there. Consequently $B_l = 0$ for all l . The coefficients A_l are found by evaluating (3.33) on the surface of the sphere:

$$V(\theta) = \sum_{l=0}^{\infty} A_l a^l P_l(\cos \theta) \quad (3.34)$$

This is just a Legendre series of the form (3.23), so that the coefficients A_l are:

$$A_l = \frac{2l+1}{2a^l} \int_0^\pi V(\theta) P_l(\cos \theta) \sin \theta d\theta \quad (3.35)$$

If, for example, $V(\theta)$ is that of Section 2.7, with two hemispheres at equal and opposite potentials,

$$V(\theta) = \begin{cases} +V, & 0 \leq \theta < \frac{\pi}{2} \\ -V, & \frac{\pi}{2} < \theta \leq \pi \end{cases}$$

then the coefficients are proportional to those in (3.27). Thus the potential inside the sphere is:

$$\Phi(r, \theta) = V \left[\frac{3}{2} \frac{r}{a} P_1(\cos \theta) - \frac{7}{8} \left(\frac{r}{a} \right)^3 P_3(\cos \theta) + \frac{11}{16} \left(\frac{r}{a} \right)^5 P_5(\cos \theta) - \cdots \right] \quad (3.36)$$

To find the potential outside the sphere we merely replace $(r/a)^l$ by $(a/r)^{l+1}$. The resulting potential can be seen to be the same as (2.27), obtained by another means.

Series (3.33), with its coefficients determined by the boundary conditions, is a unique expansion of the potential. This uniqueness provides a means of obtaining the solution of potential problems from a knowledge of the potential in a limited domain, namely on the symmetry axis. On the symmetry axis (3.33) becomes (with $z=r$):

$$\Phi(z=r) = \sum_{l=0}^{\infty} [A_l r^l + B_l r^{-(l+1)}] \quad (3.37)$$

valid for positive z . For negative z each term must be multiplied by $(-1)^l$. Suppose that, by some means, we can evaluate the potential $\Phi(z)$ at an arbitrary point z on the symmetry axis. If this potential function can be expanded in a power series in $z=r$ of the form (3.37), with known coefficients, then the solution for the potential at any point in space is obtained by multiplying each power of r^l and $r^{-(l+1)}$ by $P_l(\cos \theta)$.

At the risk of boring the reader we return to the problem of the hemispheres at equal and opposite potentials. We have already obtained the series solution in

two different ways, (2.27) and (3.36). The method just stated gives a third way. For a point on the axis we have found the closed form (2.22):

$$\Phi(z=r) = V \left[1 - \frac{r^2 - a^2}{r\sqrt{r^2 + a^2}} \right]$$

This can be expanded in powers of a^2/r^2 :

$$\Phi(z=r) = \frac{V}{\sqrt{\pi}} \sum_{j=1}^{\infty} (-1)^{j-1} \frac{(2j-\frac{1}{2})\Gamma(j-\frac{1}{2})}{j!} \left(\frac{a}{r}\right)^{2j}$$

Comparison with expansion (3.37) shows that only odd l values ($l=2j-1$) enter. The solution, valid for all points outside the sphere, is consequently:

$$\Phi(r, \theta) = \frac{V}{\sqrt{\pi}} \sum_{j=1}^{\infty} (-1)^{j-1} \frac{(2j-\frac{1}{2})\Gamma(j-\frac{1}{2})}{j!} \left(\frac{a}{r}\right)^{2j} P_{2j-1}(\cos \theta)$$

This is the same solution as already obtained, (2.27) and (3.36).

An important expansion is that of the potential at \mathbf{x} due to a unit point charge at \mathbf{x}' :

$$\frac{1}{|\mathbf{x} - \mathbf{x}'|} = \sum_{l=0}^{\infty} \frac{r_{<}^l}{r_{>}^{l+1}} P_l(\cos \gamma) \quad (3.38)$$

where $r_{<}$ ($r_{>}$) is the smaller (larger) of $|\mathbf{x}|$ and $|\mathbf{x}'|$, and γ is the angle between \mathbf{x} and \mathbf{x}' , as shown in Fig. 3.3. This can be proved by rotating axes so that \mathbf{x}' lies along the z axis. Then the potential satisfies the Laplace equation, possesses azimuthal symmetry, and can be expanded according to (3.33), except at the point $\mathbf{x} = \mathbf{x}'$:

$$\frac{1}{|\mathbf{x} - \mathbf{x}'|} = \sum_{l=0}^{\infty} (A_l r^l + B_l r^{-(l+1)}) P_l(\cos \gamma)$$

If the point \mathbf{x} is on the z axis, the right-hand side reduces to (3.37), while the left-hand side becomes:

$$\frac{1}{|\mathbf{x} - \mathbf{x}'|} = \frac{1}{(r^2 + r'^2 - 2rr' \cos \gamma)^{1/2}} \rightarrow \frac{1}{|r - r'|}$$

Fig. 3.3

Fig. 3.4 Ring of charge of radius a and total charge q located on the z axis with center at $z=b$.

Expanding, we find, for \mathbf{x} on axis,

$$\frac{1}{|\mathbf{x}-\mathbf{x}'|} = \frac{1}{r_{>}} \sum_{l=0}^{\infty} \left(\frac{r_{<}}{r_{>}} \right)^l$$

For points off the axis it is only necessary, according to (3.33) and (3.37), to multiply each term by $P_l(\cos \gamma)$. This proves the general result (3.38).

Another example is the potential due to a total charge q uniformly distributed around a circular ring of radius a , located as shown in Fig. 3.4, with its axis the z axis and its center at $z=b$. The potential at a point P on the axis of symmetry with $z=r$ is just q divided by the distance AP :

$$\Phi(z=r) = \frac{q}{(r^2 + c^2 - 2cr \cos \alpha)^{1/2}}$$

where $c^2 = a^2 + b^2$ and $\alpha = \tan^{-1}(a/b)$. The inverse distance AP can be expanded using (3.38). Thus, for $r > c$,

$$\Phi(z=r) = q \sum_{l=0}^{\infty} \frac{c^l}{r^{l+1}} P_l(\cos \alpha)$$

For $r < c$, the corresponding form is:

$$\Phi(z=r) = q \sum_{l=0}^{\infty} \frac{r^l}{c^{l+1}} P_l(\cos \alpha)$$

The potential at *any point* in space is now obtained by multiplying each member of these series by $P_l(\cos \theta)$:

$$\Phi(r, \theta) = q \sum_{l=0}^{\infty} \frac{r_{<}^l}{r_{>^{l+1}}} P_l(\cos \alpha) P_l(\cos \theta)$$

where $r_{<}$ ($r_{>}$) is the smaller (larger) of r and c .

3.4 Behavior of Fields in a Conical Hole or near a Sharp Point

Before turning to more complicated boundary value problems, we consider one with azimuthal symmetry, but with only a limited range of θ . This is a three-dimensional analog of the situation discussed in Section 2.11. Suppose that the limited angular region, $0 \leq \theta \leq \beta$, $0 \leq \phi \leq 2\pi$, is bounded by a conical conducting surface, as indicated in Fig. 3.5. For $\beta < \pi/2$, the region can be thought of as a deep conical hole bored in a conductor. For $\beta > \pi/2$, the region of space is that surrounding a pointed conical conductor.

The treatment of Section 3.2 for the Legendre differential equation needs modification. With the assumption of azimuth symmetry, (3.10) is still applicable, but we now seek solutions finite and single-valued on the range of $x = \cos \theta$ of $\cos \beta \leq x \leq 1$. Furthermore, since the conducting surface $\theta = \beta$ is at fixed potential, which we can take to be zero, the solution in $\cos \theta$ must vanish at $\theta = \beta$ to satisfy the boundary conditions. Since we demand regularity at $x = 1$ it is convenient to make a series expansion around $x = 1$ instead of $x = 0$, as was done with (3.11). With the introduction of the variable,

$$\xi = \frac{1}{2}(1 - x)$$

the Legendre equation (3.10) becomes

$$\frac{d}{d\xi} \left[\xi(1-\xi) \frac{dP}{d\xi} \right] + \nu(\nu+1)P = 0 \quad (3.39)$$

Fig. 3.5

where l has been replaced by ν to avoid confusion. The corresponding radial solutions for $U(r)/r$ in (3.2) are r^ν and $r^{-\nu-1}$. With a power series solution,

$$P(\xi) = \xi^\alpha \sum_{j=0}^{\infty} a_j \xi^j$$

substituted into (3.39), the vanishing of the coefficient of the lowest power of ξ requires $\alpha=0$. The recursion relation between successive coefficients in the series is then

$$\frac{a_{j+1}}{a_j} = \frac{(j-\nu)(j+\nu+1)}{(j+1)^2} \quad (3.40)$$

Choosing $a_0 = 1$ to normalize the solution to unity at $\xi=0$ ($\cos \theta = 1$), we have the series representation,

$$P_\nu(\xi) = 1 + \frac{(-\nu)(\nu+1)}{1!1!} \xi + \frac{(-\nu)(-\nu+1)(\nu+1)(\nu+2)}{2!2!} \xi^2 + \dots \quad (3.41)$$

We first observe that if ν is zero or a positive integer the series terminates. The reader can verify that for $\nu=l=0, 1, 2, \dots$, the series (3.41) is exactly the Legendre polynomials (3.15). For ν not equal to an integer, (3.41) represents a generalization and is called a *Legendre function of the first kind and order ν* . The series (3.41) is an example of a hypergeometric function ${}_2F_1(a, b; c; z)$ whose series expansion is

$${}_2F_1(a, b; c; z) = 1 + \frac{ab}{c} \frac{z}{1!} + \frac{a(a+1)b(b+1)}{c(c+1)} \frac{z^2}{2!} + \dots$$

Comparison with (3.41) shows that the Legendre function can be written

$$P_\nu(x) = {}_2F_1\left(-\nu, \nu+1; 1; \frac{1-x}{2}\right) \quad (3.42)$$

Here we have returned to our customary variable $x = \cos \theta$. The properties of the hypergeometric functions are well known (see *Morse and Feshbach*, Chapter 5, *Dennery and Krzywicki*, Sections IV.16–18, *Whittaker and Watson*, Chapter XIV). The Legendre function $P_\nu(x)$ is regular at $x=1$ and for $|x|<1$, but is singular at $x=-1$ unless ν is an integer. Depending upon the value of ν it has a certain number of zeros on the range $|x|<1$. Since the polynomial $P_l(x)$ has l zeros for $|x|<1$, we anticipate that for real ν more and more zeros occur as ν gets larger and larger. Furthermore, the zeros are distributed more or less uniformly on the interval. In particular, the first zero moves closer and closer to $x=1$ as ν increases.

The basic solution to the Laplace boundary-value problem of Fig. 3.5 is

$$Ar^\nu P_\nu(\cos \theta)$$

where $\nu>0$ is required for a finite potential at the origin. Since the potential

must vanish at $\theta = \beta$ for all r , it is necessary that

$$P_\nu(\cos \beta) = 0 \quad (3.43)$$

This is an eigenvalue condition on ν . From what was just stated about the zeros of P_ν it is evident that (3.43) has an infinite number of solutions, $\nu = \nu_k$ ($k = 1, 2, \dots$), which we arrange in order of increasing magnitude. For $\nu = \nu_1$, $x = \cos \beta$ is the first zero of $P_{\nu_1}(x)$. For $\nu = \nu_2$, $x = \cos \beta$ is the second zero of $P_{\nu_2}(x)$, and so on. The complete solution for the azimuthally symmetric potential in the region $0 \leq \theta \leq \beta$ is*

$$\Phi(r, \theta) = \sum_{k=1}^{\infty} A_k r^{\nu_k} P_{\nu_k}(\cos \theta) \quad (3.44)$$

In the spirit of Section 2.11 we are interested in the general behavior of the potential and fields in the neighborhood of $r = 0$ and not in the full solution with specific boundary conditions imposed at large r . Thus we approximate the behavior of the potential near $r = 0$ by the first term in (3.44) and write

$$\Phi(r, \theta) \approx A r^\nu P_\nu(\cos \theta) \quad (3.45)$$

where now ν is the *smallest root* of (3.43). The components of electric field and the surface charge density on the conical conductor are

$$\left. \begin{aligned} E_r &= -\frac{\partial \Phi}{\partial r} \approx -\nu A r^{\nu-1} P_\nu(\cos \theta) \\ E_\theta &= -\frac{1}{r} \frac{\partial \Phi}{\partial \theta} \approx A r^{\nu-1} \sin \theta P'_\nu(\cos \theta) \\ \sigma(r) &= -\frac{1}{4\pi} E_\theta|_{\theta=\beta} \approx -\frac{A}{4\pi} r^{\nu-1} \sin \beta P'_\nu(\cos \beta) \end{aligned} \right\} \quad (3.46)$$

Here the prime on P_ν denotes differential with respect to its argument. The fields and charge density all vary as $r^{\nu-1}$ as $r \rightarrow 0$.

The order ν for the first zero of $P_\nu(\cos \beta)$ is plotted as a function of β in Fig. 3.6. Obviously for $\beta \ll 1$, $\nu \gg 1$. An approximate expression for ν in this domain can be obtained from the Bessel function approximation,[†]

$$P_\nu(\cos \theta) \approx J_0\left((2\nu+1) \sin \frac{\theta}{2}\right) \quad (3.47)$$

valid for large ν and $\theta < 1$. The first zero of $J_0(x)$ is at $x = 2.405$. This gives

$$\nu \approx \frac{2.405}{\beta} - \frac{1}{2} \quad (3.48a)$$

* The orthogonality of the functions $P_{\nu_k}(\cos \theta)$ on the interval $\cos \beta \leq x \leq 1$ can be shown in the same way as for $P_l(\cos \theta)$ —see (3.17)–(3.19). Completeness can also be shown.

† Bessel functions are discussed in Section 3.7.

Fig. 3.6 The order parameter ν for the first zero of $P_\nu(\cos \beta)$ versus β in degrees. The range $0 < \beta < 90^\circ$ corresponds to a conical hole, while $90^\circ < \beta < 180^\circ$ represents a conical point. Near $r=0$ the fields and surface charge density are proportional to $r^{\nu-1}$. The dotted curves are the approximate expressions, (3.48a) and (3.48b).

Since $|\mathbf{E}|$ and σ vary as $r^{\nu-1}$ there are evidently very small fields and very little charge deep in a conical hole as $\beta \rightarrow 0$. For $\beta = \pi/2$, the conical conductor becomes a plane. There $\nu = 1$ and $\sigma \propto 1$, as expected. For $\beta > \pi/2$, the geometry is that of a conical point. Then $\nu < 1$ and the field is singular at $r=0$. For $\beta \rightarrow \pi$, $\nu \rightarrow 0$, but rather slowly. An approximation for $(\pi - \beta)$ small is

$$\nu \approx \left[2 \ln \left(\frac{2}{\pi - \beta} \right) \right]^{-1} \quad (3.48b)$$

This shows that for $(\pi - \beta) \approx 10^\circ$, $\nu \approx 0.2$ and even for $(\pi - \beta) \approx 1^\circ$, $\nu \approx 0.1$. In any event, for a narrow conical point the fields near the point vary as $r^{-1+\epsilon}$ where $\epsilon \ll 1$. Very high fields exist around the point. The efficacy of such points in lightning rods is discussed in Section 2.11.

An extended discussion of potential problems of this general kind is given by R. N. Hall, *J. Appl. Phys.* **20**, 925 (1949). He has graphs for a number of the roots ν_k of (3.43) as functions of β .

3.5 Associated Legendre Functions and the Spherical Harmonics $Y_{lm}(\theta, \phi)$

So far we have dealt with potential problems possessing azimuthal symmetry with solutions of the form (3.33). Unless the range in θ is restricted, as in Section 3.4, these involve only ordinary Legendre polynomials. The general potential problem can, however, have azimuthal variations so that $m \neq 0$ in (3.5) and (3.9). Then we need the generalization of $P_l(\cos \theta)$, namely, the solution of (3.9) with l and m both arbitrary. In essentially the same manner as for the ordinary Legendre functions it can be shown that in order to have finite solutions on the interval $-1 \leq x \leq 1$ the parameter l must be zero or a positive integer and that the integer m can take on only the values $-l, -(l-1), \dots, 0, \dots, (l-1), l$. The solution having these properties is called an associated Legendre function $P_l^m(x)$. For positive m it is defined by the formula:*

$$P_l^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_l(x) \quad (3.49)$$

If Rodrigues' formula is used to represent $P_l(x)$, a definition valid for both positive and negative m is obtained:

$$P_l^m(x) = \frac{(-1)^m}{2^l l!} (1-x^2)^{m/2} \frac{d^{l+m}}{dx^{l+m}} (x^2-1)^l \quad (3.50)$$

$P_l^{-m}(x)$ and $P_l^m(x)$ are proportional, since differential equation (3.9) depends only on m^2 and m is an integer. It can be shown that

$$P_l^{-m}(x) = (-1)^m \frac{(l-m)!}{(l+m)!} P_l^m(x) \quad (3.51)$$

For fixed m the functions $P_l^m(x)$ form an orthogonal set in the index l on the interval $-1 \leq x \leq 1$. By the same means as for the Legendre functions the orthogonality relation can be obtained:

$$\int_{-1}^1 P_r^m(x) P_l^m(x) dx = \frac{2}{2l+1} \frac{(l+m)!}{(l-m)!} \delta_{rl} \quad (3.52)$$

The solution of the Laplace equation was decomposed into a product of factors for the three variables r , θ , and ϕ . It is convenient to combine the angular

* The choice of phase for $P_l^m(x)$ is that of Magnus and Oberhettinger, and of E. U. Condon and G. H. Shortley in *Theory of Atomic Spectra*, Cambridge University Press (1953). For explicit expressions and recursion formulas, see Magnus and Oberhettinger, p. 54.

factors and construct orthonormal functions over the unit sphere. We will call these functions *spherical harmonics*, although this terminology is often reserved for solutions of the generalized Legendre equation (3.9). Our spherical harmonics are sometimes called “tesseral harmonics” in older books. The functions $Q_m(\phi) = e^{im\phi}$ form a complete set of orthogonal functions in the index m on the interval $0 \leq \phi \leq 2\pi$. The functions $P_l^m(\cos \theta)$ form a similar set in the index l for each m value on the interval $-1 \leq \cos \theta \leq 1$. Therefore their product $P_l^m Q_m$ will form a complete orthogonal set on the surface of the unit sphere in the two indices l, m . From the normalization condition (3.52) it is clear that the suitably normalized functions, denoted by $Y_{lm}(\theta, \phi)$, are:

$$Y_{lm}(\theta, \phi) = \sqrt{\frac{2l+1}{4\pi} \frac{(l-m)!}{(l+m)!}} P_l^m(\cos \theta) e^{im\phi} \quad (3.53)$$

From (3.51) it can be seen that

$$Y_{l,-m}(\theta, \phi) = (-1)^m Y_{lm}^*(\theta, \phi) \quad (3.54)$$

The normalization and orthogonality conditions are

$$\int_0^{2\pi} d\phi \int_0^\pi \sin \theta d\theta Y_{lm}^*(\theta, \phi) Y_{l'm'}(\theta, \phi) = \delta_{ll'} \delta_{mm'} \quad (3.55)$$

The completeness relation, equivalent to (2.35), is

$$\sum_{l=0}^{\infty} \sum_{m=-l}^l Y_{lm}^*(\theta', \phi') Y_{lm}(\theta, \phi) = \delta(\phi - \phi') \delta(\cos \theta - \cos \theta') \quad (3.56)$$

For a few small l values and $m \geq 0$ the table shows the explicit form of the $Y_{lm}(\theta, \phi)$. For negative m values (3.54) can be used.

Spherical harmonics $Y_{lm}(\theta, \phi)$

$$\begin{aligned} l=0 & \quad Y_{00} = \frac{1}{\sqrt{4\pi}} \\ l=1 & \quad \begin{cases} Y_{11} = -\sqrt{\frac{3}{8\pi}} \sin \theta e^{i\phi} \\ Y_{10} = \sqrt{\frac{3}{4\pi}} \cos \theta \end{cases} \\ l=2 & \quad \begin{cases} Y_{22} = \frac{1}{4} \sqrt{\frac{15}{2\pi}} \sin^2 \theta e^{2i\phi} \\ Y_{21} = -\sqrt{\frac{15}{8\pi}} \sin \theta \cos \theta e^{i\phi} \\ Y_{20} = \sqrt{\frac{5}{4\pi}} \left(\frac{3}{2} \cos^2 \theta - \frac{1}{2} \right) \end{cases} \end{aligned}$$

$$l=3 \quad \left\{ \begin{array}{l} Y_{33} = -\frac{1}{4} \sqrt{\frac{35}{4\pi}} \sin^3 \theta e^{3i\phi} \\ Y_{32} = \frac{1}{4} \sqrt{\frac{105}{2\pi}} \sin^2 \theta \cos \theta e^{2i\phi} \\ Y_{31} = -\frac{1}{4} \sqrt{\frac{21}{4\pi}} \sin \theta (5 \cos^2 \theta - 1) e^{i\phi} \\ Y_{30} = \sqrt{\frac{7}{4\pi}} \left(\frac{5}{2} \cos^3 \theta - \frac{3}{2} \cos \theta \right) \end{array} \right.$$

Note that, for $m=0$,

$$Y_{l0}(\theta, \phi) = \sqrt{\frac{2l+1}{4\pi}} P_l(\cos \theta) \quad (3.57)$$

An arbitrary function $g(\theta, \phi)$ can be expanded in spherical harmonics:

$$g(\theta, \phi) = \sum_{l=0}^{\infty} \sum_{m=-l}^l A_{lm} Y_{lm}(\theta, \phi) \quad (3.58)$$

where the coefficients are

$$A_{lm} = \int d\Omega Y_{lm}^*(\theta, \phi) g(\theta, \phi)$$

A point of interest to us in the next section is the form of the expansion for $\theta=0$. With definition (3.57), we find:

$$[g(\theta, \phi)]_{\theta=0} = \sum_{l=0}^{\infty} \sqrt{\frac{2l+1}{4\pi}} A_{l0} \quad (3.59)$$

where

$$A_{l0} = \sqrt{\frac{2l+1}{4\pi}} \int d\Omega P_l(\cos \theta) g(\theta, \phi) \quad (3.60)$$

All terms in the series with $m \neq 0$ vanish at $\theta=0$.

The general solution for a boundary-value problem in spherical coordinates can be written in terms of spherical harmonics and powers of r in a generalization of (3.33):

$$\Phi(r, \theta, \phi) = \sum_{l=0}^{\infty} \sum_{m=-l}^l [A_{lm} r^l + B_{lm} r^{-(l+1)}] Y_{lm}(\theta, \phi) \quad (3.61)$$

If the potential is specified on a spherical surface, the coefficients can be determined by evaluating (3.61) on the surface and using (3.58).

3.6 Addition Theorem for Spherical Harmonics

A mathematical result of considerable interest and use is called the *addition theorem* for spherical harmonics. Two coordinate vectors \mathbf{x} and \mathbf{x}' , with spherical coordinates (r, θ, ϕ) and (r', θ', ϕ') , respectively, have an angle γ between them,

Fig. 3.7

as shown in Fig. 3.7. The addition theorem expresses a Legendre polynomial of order l in the angle γ in terms of products of the spherical harmonics of the angles θ , ϕ and θ' , ϕ' :

$$P_l(\cos \gamma) = \frac{4\pi}{2l+1} \sum_{m=-l}^l Y_{lm}^*(\theta', \phi') Y_{lm}(\theta, \phi) \quad (3.62)$$

where $\cos \gamma = \cos \theta \cos \theta' + \sin \theta \sin \theta' \cos(\phi - \phi')$. To prove this theorem we consider the vector \mathbf{x}' as fixed in space. Then $P_l(\cos \gamma)$ is a function of the angles θ , ϕ , with the angles θ' , ϕ' as parameters. It may be expanded in a series (3.58):

$$P_l(\cos \gamma) = \sum_{l'=0}^{\infty} \sum_{m=-l'}^{l'} A_{l'm}(\theta', \phi') Y_{l'm}(\theta, \phi) \quad (3.63)$$

Comparison with (3.62) shows that only terms with $l' = l$ appear. To see why this is so, note that, if coordinate axes are chosen so that \mathbf{x}' is on the z axis, then γ becomes the usual polar angle and $P_l(\cos \gamma)$ satisfies the equation:

$$\nabla'^2 P_l(\cos \gamma) + \frac{l(l+1)}{r^2} P_l(\cos \gamma) = 0 \quad (3.64)$$

where ∇'^2 is the Laplacian referred to these new axes. If the axes are now rotated to the position shown in Fig. 3.7, $\nabla'^2 = \nabla^2$ and r is unchanged.* Consequently $P_l(\cos \gamma)$ still satisfies an equation of the form (3.64); i.e., it is a spherical harmonic of order l . This means that it is a linear combination of Y_{lm} 's of that order only:

$$P_l(\cos \gamma) = \sum_{m=-l}^l A_m(\theta', \phi') Y_{lm}(\theta, \phi) \quad (3.65)$$

The coefficients $A_m(\theta', \phi')$ are given by:

$$A_m(\theta', \phi') = \int Y_{lm}^*(\theta, \phi) P_l(\cos \gamma) d\Omega \quad (3.66)$$

* The proof that $\nabla'^2 = \nabla^2$ under rotations follows most easily from noting that $\nabla^2 \psi = \nabla \cdot \nabla \psi$ is an operator scalar product, and that all scalar products are invariant under rotations.

To evaluate this coefficient we note that it may be viewed, according to (3.60), as the $m'=0$ coefficient in an expansion of the function $\sqrt{4\pi/(2l+1)} Y_{lm}^*(\theta, \phi)$ in a series of $Y_{lm}(\gamma, \beta)$ referred to the primed axis of (3.64). From (3.59) it is then found that, since only one l value is present, coefficient (3.66) is

$$A_m(\theta', \phi') = \frac{4\pi}{2l+1} \{Y_{lm}^*[\theta(\gamma, \beta), \phi(\gamma, \beta)]\}_{\gamma=0} \quad (3.67)$$

In the limit $\gamma \rightarrow 0$, the angles (θ, ϕ) , as functions of (γ, β) , go over into (θ', ϕ') . Thus addition theorem (3.62) is proved. Sometimes the theorem is written in terms of $P_l^m(\cos \theta)$ rather than Y_{lm} . Then it has the form:

$$P_l(\cos \gamma) = P_l(\cos \theta)P_l(\cos \theta') + 2 \sum_{m=1}^l \frac{(l-m)!}{(l+m)!} P_l^m(\cos \theta)P_l^m(\cos \theta') \cos [m(\phi - \phi')] \quad (3.68)$$

If the angle γ goes to zero, there results a “sum rule” for the squares of Y_{lm} ’s:

$$\sum_{m=-l}^l |Y_{lm}(\theta, \phi)|^2 = \frac{2l+1}{4\pi} \quad (3.69)$$

The addition theorem can be used to put expansion (3.38) of the potential at \mathbf{x} due to a unit charge at \mathbf{x}' into its most general form. Substituting (3.62) for $P_l(\cos \gamma)$ into (3.38) we obtain

$$\frac{1}{|\mathbf{x} - \mathbf{x}'|} = 4\pi \sum_{l=0}^{\infty} \sum_{m=-l}^l \frac{1}{2l+1} \frac{r_{<}^l}{r_{>}^{l+1}} Y_{lm}^*(\theta', \phi') Y_{lm}(\theta, \phi) \quad (3.70)$$

Equation (3.70) gives the potential in a completely factorized form in the coordinates \mathbf{x} and \mathbf{x}' . This is useful in any integrations over charge densities, etc., where one variable is the variable of integration and the other is the coordinate of the observation point. The price paid is that there is a double sum involved, rather than a single term.

3.7 Laplace Equation in Cylindrical Coordinates, Bessel Functions

In cylindrical coordinates (ρ, ϕ, z) , as shown in Fig. 3.8, the Laplace equation takes the form:

$$\frac{\partial^2 \Phi}{\partial \rho^2} + \frac{1}{\rho} \frac{\partial \Phi}{\partial \rho} + \frac{1}{\rho^2} \frac{\partial^2 \Phi}{\partial \phi^2} + \frac{\partial^2 \Phi}{\partial z^2} = 0 \quad (3.71)$$

The separation of variables is accomplished by the substitution:

$$\Phi(\rho, \phi, z) = R(\rho)Q(\phi)Z(z) \quad (3.72)$$

Fig. 3.8

In the usual way this leads to the three ordinary differential equations:

$$\frac{d^2 Z}{dz^2} - k^2 Z = 0 \quad (3.73)$$

$$\frac{d^2 Q}{d\phi^2} + \nu^2 Q = 0 \quad (3.74)$$

$$\frac{d^2 R}{d\rho^2} + \frac{1}{\rho} \frac{dR}{d\rho} + \left(k^2 - \frac{\nu^2}{\rho^2} \right) R = 0 \quad (3.75)$$

The solutions of the first two equations are elementary:

$$\begin{aligned} Z(z) &= e^{\pm kz} \\ Q(\phi) &= e^{\pm i\nu\phi} \end{aligned} \quad (3.76)$$

In order that the potential be single valued when the full azimuth is allowed, ν must be an integer. But barring some boundary-condition requirement in the z direction, the parameter k is arbitrary. For the present we will assume that k is real and positive.

The radial equation can be put in a standard form by the change of variable $x = k\rho$. Then it becomes

$$\frac{d^2 R}{dx^2} + \frac{1}{x} \frac{dR}{dx} + \left(1 - \frac{\nu^2}{x^2} \right) R = 0 \quad (3.77)$$

This is the Bessel equation, and the solutions are called *Bessel functions* of order ν . If a power series solution of the form:

$$R(x) = x^\alpha \sum_{j=0}^{\infty} a_j x^j \quad (3.78)$$

is assumed, then it is found that

$$\alpha = \pm \nu \quad (3.79)$$

and

$$a_{2j} = -\frac{1}{4j(j+\alpha)} a_{2j-2} \quad (3.80)$$

for $j = 1, 2, 3, \dots$. All odd powers of x^j have vanishing coefficients. The recursion formula can be iterated to obtain

$$a_{2j} = \frac{(-1)^j \Gamma(\alpha+1)}{2^{2j} j! \Gamma(j+\alpha+1)} a_0 \quad (3.81)$$

It is conventional to choose the constant $a_0 = [2^\alpha \Gamma(\alpha+1)]^{-1}$. Then the two solutions are

$$J_\nu(x) = \left(\frac{x}{2}\right)^\nu \sum_{j=0}^{\infty} \frac{(-1)^j}{j! \Gamma(j+\nu+1)} \left(\frac{x}{2}\right)^{2j} \quad (3.82)$$

$$J_{-\nu}(x) = \left(\frac{x}{2}\right)^{-\nu} \sum_{j=0}^{\infty} \frac{(-1)^j}{j! \Gamma(j-\nu+1)} \left(\frac{x}{2}\right)^{2j} \quad (3.83)$$

These solutions are called Bessel functions of the first kind of order $\pm\nu$. The series converge for all finite values of x . If ν is *not an integer*, these two solutions $J_{\pm\nu}(x)$ form a pair of linearly independent solutions to the second-order Bessel equation. However, if ν is an integer, it is well known that the solutions are linearly dependent. In fact, for $\nu = m$, an integer, it can be seen from the series representation that

$$J_{-m}(x) = (-1)^m J_m(x) \quad (3.84)$$

Consequently it is necessary to find another linearly independent solution when m is an integer. It is customary, even if ν is not an integer, to replace the pair $J_{\pm\nu}(x)$ by $J_\nu(x)$ and $N_\nu(x)$, the Neumann function (or Bessel function of the second kind):

$$N_\nu(x) = \frac{J_\nu(x) \cos \nu\pi - J_{-\nu}(x)}{\sin \nu\pi} \quad (3.85)$$

For ν not an integer, $N_\nu(x)$ is clearly linearly independent of $J_\nu(x)$. In the limit $\nu \rightarrow \text{integer}$, it can be shown that $N_\nu(x)$ is still linearly independent of $J_\nu(x)$. As expected, it involves $\log x$. Its series representation is given in the reference books.

The Bessel functions of the third kind, called *Hankel functions*, are defined as linear combinations of $J_\nu(x)$ and $N_\nu(x)$:

$$\begin{aligned} H_\nu^{(1)}(x) &= J_\nu(x) + iN_\nu(x) \\ H_\nu^{(2)}(x) &= J_\nu(x) - iN_\nu(x) \end{aligned} \quad (3.86)$$

The Hankel functions form a fundamental set of solutions to the Bessel equation, just as do $J_\nu(x)$ and $N_\nu(x)$.

The functions J_ν , N_ν , $H_\nu^{(1)}$, $H_\nu^{(2)}$ all satisfy the recursion formulas:

$$\Omega_{\nu-1}(x) + \Omega_{\nu+1}(x) = \frac{2\nu}{x} \Omega_\nu(x) \quad (3.87)$$

$$\Omega_{\nu-1}(x) - \Omega_{\nu+1}(x) = 2 \frac{d\Omega_\nu(x)}{dx} \quad (3.88)$$

where $\Omega_\nu(x)$ is any one of the cylinder functions of order ν . These may be verified directly from the series representation (3.82).

For reference purposes, the limiting forms of the various kinds of Bessel functions will be given for small and large values of their argument. Only the leading terms will be given for simplicity:

$$x \ll 1 \quad J_\nu(x) \rightarrow \frac{1}{\Gamma(\nu+1)} \left(\frac{x}{2}\right)^\nu \quad (3.89)$$

$$N_\nu(x) \rightarrow \begin{cases} \frac{2}{\pi} \left[\ln \left(\frac{x}{2}\right) + 0.5772 \cdots \right], & \nu = 0 \\ -\frac{\Gamma(\nu)}{\pi} \left(\frac{2}{x}\right)^\nu, & \nu \neq 0 \end{cases} \quad (3.90)$$

In these formulas ν is assumed to be real and nonnegative.

$$\begin{aligned} x \gg 1, \nu \quad J_\nu(x) &\rightarrow \sqrt{\frac{2}{\pi x}} \cos \left(x - \frac{\nu\pi}{2} - \frac{\pi}{4} \right) \\ N_\nu(x) &\rightarrow \sqrt{\frac{2}{\pi x}} \sin \left(x - \frac{\nu\pi}{2} - \frac{\pi}{4} \right) \end{aligned} \quad (3.91)$$

The transition from the small x behavior to the large x asymptotic form occurs in the region of $x \sim \nu$.

From the asymptotic forms (3.91) it is clear that each Bessel function has an infinite number of roots. We will be chiefly concerned with the roots of $J_\nu(x)$:

$$J_\nu(x_{\nu n}) = 0, \quad n = 1, 2, 3, \dots \quad (3.92)$$

$x_{\nu n}$ is the n th root of $J_\nu(x)$. For the first few integer values of ν , the first three roots are:

$$\nu = 0, \quad x_{0n} = 2.405, 5.520, 8.654, \dots$$

$$\nu = 1, \quad x_{1n} = 3.832, 7.016, 10.173, \dots$$

$$\nu = 2, \quad x_{2n} = 5.136, 8.417, 11.620, \dots$$

For higher roots, the asymptotic formula

$$x_{\nu n} \approx n\pi + \left(\nu - \frac{1}{2}\right) \frac{\pi}{2}$$

gives adequate accuracy (to at least three figures). Tables of roots are given in *Jahnke, Emde and Lösch*, p. 194 and *Abramowitz and Stegun*, p. 409.

Having found the solution of the radial part of the Laplace equation in terms of Bessel functions, we can now ask in what sense the Bessel functions form an orthogonal, complete set of functions. We will consider only Bessel functions of the first kind, and will show that $\sqrt{\rho} J_\nu(x_{\nu n}\rho/a)$, for fixed $\nu \geq 0$, $n = 1, 2, \dots$, form an orthogonal set on the interval $0 \leq \rho \leq a$. The demonstration starts with the differential equation satisfied by $J_\nu(x_{\nu n}\rho/a)$:

$$\frac{1}{\rho} \frac{d}{d\rho} \left[\rho \frac{dJ_\nu\left(x_{\nu n} \frac{\rho}{a}\right)}{d\rho} \right] + \left(\frac{x_{\nu n}^2}{a^2} - \frac{\nu^2}{\rho^2} \right) J_\nu\left(x_{\nu n} \frac{\rho}{a}\right) = 0 \quad (3.93)$$

If we multiply the equation by $\rho J_\nu(x_{\nu n'}\rho/a)$ and integrate from 0 to a , we obtain

$$\int_0^a J_\nu\left(x_{\nu n'} \frac{\rho}{a}\right) \frac{d}{d\rho} \left[\rho \frac{dJ_\nu\left(x_{\nu n} \frac{\rho}{a}\right)}{d\rho} \right] d\rho + \int_0^a \left(\frac{x_{\nu n}^2}{a^2} - \frac{\nu^2}{\rho^2} \right) \rho J_\nu\left(x_{\nu n'} \frac{\rho}{a}\right) J_\nu\left(x_{\nu n} \frac{\rho}{a}\right) d\rho = 0$$

Integration by parts, combined with the vanishing of $(\rho J_\nu J'_\nu)$ at $\rho = 0$ (for $\nu \geq 0$) and $\rho = a$, leads to the result:

$$-\int_0^a \rho \frac{dJ_\nu\left(x_{\nu n'} \frac{\rho}{a}\right)}{d\rho} \frac{dJ_\nu\left(x_{\nu n} \frac{\rho}{a}\right)}{d\rho} d\rho + \int_0^a \left(\frac{x_{\nu n}^2}{a^2} - \frac{\nu^2}{\rho^2} \right) \rho J_\nu\left(x_{\nu n'} \frac{\rho}{a}\right) J_\nu\left(x_{\nu n} \frac{\rho}{a}\right) d\rho = 0$$

If we now write down the same expression, with n and n' interchanged, and subtract, we obtain the orthogonality condition:

$$(x_{\nu n}^2 - x_{\nu n'}^2) \int_0^a \rho J_\nu\left(x_{\nu n'} \frac{\rho}{a}\right) J_\nu\left(x_{\nu n} \frac{\rho}{a}\right) d\rho = 0 \quad (3.94)$$

By means of the recursion formulas (3.87) and (3.88) and the differential equation, the normalization integral can be found to be:

$$\int_0^a \rho J_\nu\left(x_{\nu n'} \frac{\rho}{a}\right) J_\nu\left(x_{\nu n} \frac{\rho}{a}\right) d\rho = \frac{a^2}{2} [J_{\nu+1}(x_{\nu n})]^2 \delta_{n'n} \quad (3.95)$$

Assuming that the set of Bessel functions is complete, we can expand an arbitrary function of ρ on the interval $0 \leq \rho \leq a$ in a Fourier-Bessel series:

$$f(\rho) = \sum_{n=1}^{\infty} A_{\nu n} J_\nu\left(x_{\nu n} \frac{\rho}{a}\right) \quad (3.96)$$

where

$$A_{\nu n} = \frac{2}{a^2 J_{\nu+1}^2(x_{\nu n})} \int_0^a \rho f(\rho) J_\nu\left(x_{\nu n} \frac{\rho}{a}\right) d\rho \quad (3.97)$$

Our derivation of (3.96) involved the restriction $\nu \geq 0$. Actually it can be proved to hold for all $\nu \geq -1$.

Expansion (3.96) and (3.97) is the conventional Fourier-Bessel series and is particularly appropriate to functions which vanish at $\rho = a$ (e.g., homogeneous Dirichlet boundary conditions on a cylinder; see the following section). But it will be noted that an alternative expansion is possible in a series of functions $\sqrt{\rho} J_\nu(y_{\nu n}\rho/a)$ where $y_{\nu n}$ is the n th root of the equation $[dJ_\nu(x)]/dx = 0$. The reason is that, in proving the orthogonality of the functions, all that is demanded is that the quantity $[\rho J_\nu(\lambda\rho)(d/d\rho)J_\nu(\lambda'\rho)]$ vanish at the end points $\rho = 0$ and $\rho = a$. The requirement is met by either $\lambda = x_{\nu n}/a$ or $\lambda = y_{\nu n}/a$, where $J_\nu(x_{\nu n}) = 0$ and $J'_\nu(y_{\nu n}) = 0$. The expansion in terms of the set $\sqrt{\rho} J_\nu(y_{\nu n}\rho/a)$ is especially useful for functions with vanishing slope at $\rho = a$. (See Problem 3.10.)

A Fourier-Bessel series is only one type of expansion involving Bessel functions. Neumann series $\left[\sum_{n=0}^{\infty} a_n J_{\nu+n}(z) \right]$, Kapteyn series $\left[\sum_{n=0}^{\infty} a_n J_{\nu+n}((\nu+n)z) \right]$, and Schlömilch series $\left[\sum_{n=1}^{\infty} a_n J_\nu(nx) \right]$ are some of the other possibilities. The reader may refer to Watson, Chapters XVI–XIX, for a detailed discussion of the properties of these series. Kapteyn series occur in the discussion of the Kepler motion of planets and of radiation by rapidly moving charges (see Problems 14.7 and 14.8).

Before leaving the properties of Bessel functions it should be noted that if, in the separation of the Laplace equation, the separation constant k^2 in (3.73) had been taken as $-k^2$, then $Z(z)$ would have been $\sin kz$ or $\cos kz$ and the equation for $R(\rho)$ would have been:

$$\frac{d^2 R}{d\rho^2} + \frac{1}{\rho} \frac{dR}{d\rho} - \left(k^2 + \frac{\nu^2}{\rho^2} \right) R = 0 \quad (3.98)$$

With $k\rho = x$, this becomes

$$\frac{d^2 R}{dx^2} + \frac{1}{x} \frac{dR}{dx} - \left(1 + \frac{\nu^2}{x^2} \right) R = 0 \quad (3.99)$$

The solutions of this equation are called *modified Bessel functions*. It is evident that they are just Bessel functions of pure imaginary argument. The usual choices of linearly independent solutions are denoted by $I_\nu(x)$ and $K_\nu(x)$. They are defined by

$$I_\nu(x) = i^{-\nu} J_\nu(ix) \quad (3.100)$$

$$K_\nu(x) = \frac{\pi}{2} i^{\nu+1} H_\nu^{(1)}(ix) \quad (3.101)$$

and are real functions for real x and ν . Their limiting forms for small and large x

are, assuming real $\nu \geq 0$:

$$x \ll 1 \quad I_\nu(x) \rightarrow \frac{1}{\Gamma(\nu+1)} \left(\frac{x}{2}\right)^\nu \quad (3.102)$$

$$K_\nu(x) \rightarrow \begin{cases} -\left[\ln\left(\frac{x}{2}\right) + 0.5772 \dots\right], & \nu = 0 \\ \frac{\Gamma(\nu)}{2} \left(\frac{2}{x}\right)^\nu, & \nu \neq 0 \end{cases} \quad (3.103)$$

$$x \gg 1, \nu \quad \left. \begin{aligned} I_\nu(x) &\rightarrow \frac{1}{\sqrt{2\pi x}} e^x \left[1 + O\left(\frac{1}{x}\right)\right] \\ K_\nu(x) &\rightarrow \sqrt{\frac{\pi}{2x}} e^{-x} \left[1 + O\left(\frac{1}{x}\right)\right] \end{aligned} \right\} \quad (3.104)$$

3.8 Boundary-Value Problems in Cylindrical Coordinates

The solution of the Laplace equation in cylindrical coordinates is $\Phi = R(\rho)Q(\phi)Z(z)$, where the separate factors are given in the previous section. Consider now the specific boundary-value problem shown in Fig. 3.9. The cylinder has a radius a and a height L , the top and bottom surfaces being at $z = L$ and $z = 0$. The potential on the side and the bottom of the cylinder is zero, while the top has a potential $\Phi = V(\rho, \phi)$. We want to find the potential at any point inside the cylinder. In order that Φ be single valued and vanish at $z = 0$,

$$\left. \begin{aligned} Q(\phi) &= A \sin m\phi + B \cos m\phi \\ Z(z) &= \sinh kz \end{aligned} \right\} \quad (3.105)$$

Fig. 3.9

where $\nu = m$ is an integer and k is a constant to be determined. The radial factor is

$$R(\rho) = CJ_m(k\rho) + DN_m(k\rho) \quad (3.106)$$

If the potential is finite at $\rho = 0$, $D = 0$. The requirement that the potential vanish at $\rho = a$ means that k can take on only those special values:

$$k_{mn} = \frac{x_{mn}}{a}, \quad n = 1, 2, 3, \dots \quad (3.107)$$

where x_{mn} are the roots of $J_m(x_{mn}) = 0$.

Combining all these conditions, we find that the general form of the solution is

$$\Phi(\rho, \phi, z) = \sum_{m=0}^{\infty} \sum_{n=1}^{\infty} J_m(k_{mn}\rho) \sinh(k_{mn}z) (A_{mn} \sin m\phi + B_{mn} \cos m\phi) \quad (3.108)$$

At $z = L$, we are given the potential as $V(\rho, \phi)$. Therefore we have

$$V(\rho, \phi) = \sum_{m,n} \sinh(k_{mn}L) J_m(k_{mn}\rho) (A_{mn} \sin m\phi + B_{mn} \cos m\phi)$$

This is a Fourier series in ϕ and a Fourier-Bessel series in ρ . The coefficients are, from (2.37) and (3.97),

$$\left. \begin{aligned} A_{mn} &= \frac{2 \operatorname{cosech}(k_{mn}L)}{\pi a^2 J_{m+1}^2(k_{mn}a)} \int_0^{2\pi} d\phi \int_0^a d\rho \rho V(\rho, \phi) J_m(k_{mn}\rho) \sin m\phi \\ B_{mn} &= \frac{2 \operatorname{cosech}(k_{mn}L)}{\pi a^2 J_{m+1}^2(k_{mn}a)} \int_0^{2\pi} d\phi \int_0^a d\rho \rho V(\rho, \phi) J_m(k_{mn}\rho) \cos m\phi \end{aligned} \right\} \quad (3.109)$$

with the proviso that, for $m=0$, we use $\frac{1}{2}B_{0n}$ in the series.

The particular form of expansion (3.108) is dictated by the requirement that the potential vanish at $z=0$ for arbitrary ρ and at $\rho=a$ for arbitrary z . For different boundary conditions the expansion would take a different form. An example where the potential is zero on the end faces and equal to $V(\phi, z)$ on the side surface is left as Problem 3.8 for the reader.

The Fourier-Bessel series (3.108) is appropriate for a finite interval in ρ , $0 \leq \rho \leq a$. If $a \rightarrow \infty$, the series goes over into an integral in a manner entirely analogous to the transition from a trigonometric Fourier series to a Fourier integral. Thus, for example, if the potential in charge-free space is finite for $z \geq 0$ and vanishes for $z \rightarrow \infty$, the general form of the solution for $z \geq 0$ must be

$$\Phi(\rho, \phi, z) = \sum_{m=0}^{\infty} \int_0^{\infty} dk e^{-kz} J_m(k\rho) [A_m(k) \sin m\phi + B_m(k) \cos m\phi] \quad (3.110)$$

If the potential is specified over the whole plane $z=0$ to be $V(\rho, \phi)$ the coefficients are determined by

$$V(\rho, \phi) = \sum_{m=0}^{\infty} \int_0^{\infty} dk J_m(k\rho) [A_m(k) \sin m\phi + B_m(k) \cos m\phi]$$

The variation in ϕ is just a Fourier series. Consequently the coefficients $A_m(k)$ and $B_m(k)$ are separately specified by the integral relations:

$$\frac{1}{\pi} \int_0^{2\pi} V(\rho, \phi) \begin{Bmatrix} \sin m\phi \\ \cos m\phi \end{Bmatrix} d\phi = \int_0^\infty J_m(k'\rho) \begin{Bmatrix} A_m(k') \\ B_m(k') \end{Bmatrix} dk' \quad (3.111)$$

These radial integral equations of the first kind can be easily solved, since they are *Hankel transforms*. For our purposes, the integral relation,

$$\int_0^\infty x J_m(kx) J_m(k'x) dx = \frac{1}{k} \delta(k' - k) \quad (3.112)$$

can be exploited to invert equations (3.111). Multiplying both sides by $\rho J_m(k\rho)$ and integrating over ρ , we find with the help of (3.112) that the coefficients are determined by integrals over the whole area of the plane $z=0$:

$$\begin{Bmatrix} A_m(k) \\ B_m(k) \end{Bmatrix} = \frac{k}{\pi} \int_0^\infty d\rho \rho \int_0^{2\pi} d\phi V(\rho, \phi) J_m(k\rho) \begin{Bmatrix} \sin m\phi \\ \cos m\phi \end{Bmatrix} \quad (3.113)$$

As usual, for $m=0$, we must use $\frac{1}{2}B_0(k)$ in series (3.110).

3.9 Expansion of Green Functions in Spherical Coordinates

In order to handle problems involving distributions of charge as well as boundary values for the potential (i.e., solutions of the Poisson equation) it is necessary to determine the Green function $G(\mathbf{x}, \mathbf{x}')$ which satisfies the appropriate boundary conditions. Often these boundary conditions are specified on surfaces of some separable coordinate system, e.g., spherical or cylindrical boundaries. Then it is convenient to express the Green function as a series of products of the functions appropriate to the coordinates in question. We first illustrate the type of expansion involved by considering spherical coordinates.

For the case of no boundary surfaces, except at infinity, we already have the expansion of the Green function, namely (3.70):

$$\frac{1}{|\mathbf{x} - \mathbf{x}'|} = 4\pi \sum_{l=0}^{\infty} \sum_{m=-l}^l \frac{1}{2l+1} \frac{r_{<}^l}{r_{>}^{l+1}} Y_{lm}^*(\theta', \phi') Y_{lm}(\theta, \phi)$$

Suppose that we wish to obtain a similar expansion for the Green function appropriate for the “exterior” problem with a spherical boundary at $r=a$. The result is readily found from the image form of the Green function (2.16). Using expansion (3.70) for both terms in (2.16), we obtain:

$$G(\mathbf{x}, \mathbf{x}') = 4\pi \sum_{l,m} \frac{1}{2l+1} \left[\frac{r_{<}^l}{r_{>}^{l+1}} - \frac{1}{a} \left(\frac{a^2}{rr'} \right)^{l+1} \right] Y_{lm}^*(\theta', \phi') Y_{lm}(\theta, \phi) \quad (3.114)$$

To see clearly the structure of (3.114) and to verify that it satisfies the boundary

conditions, we exhibit the radial factors separately for $r < r'$ and for $r > r'$:

$$\left[\begin{array}{l} r < r' \\ r > r' \end{array} \right] - \frac{1}{a} \left(\frac{a^2}{rr'} \right)^{l+1} = \begin{cases} \frac{1}{r^{l+1}} \left[r^l - \frac{a^{2l+1}}{r^{l+1}} \right], & r < r' \\ \left[r^l - \frac{a^{2l+1}}{r^{l+1}} \right] \frac{1}{r^{l+1}}, & r > r' \end{cases} \quad (3.115)$$

First of all, we note that for either r or r' equal to a the radial factor vanishes, as required. Similarly, as r or $r' \rightarrow \infty$, the radial factor vanishes. It is symmetric in r and r' . Viewed as a function of r , for fixed r' , the radial factor is just a linear combination of the solutions r^l and $r^{-(l+1)}$ of the radial part (3.7) of the Laplace equation. It is admittedly a different linear combination for $r < r'$ and for $r > r'$. The reason for this will become apparent below, and is connected with the fact that the Green function is a solution of the Poisson equation with a delta function inhomogeneity.

Now that we have seen the general structure of the expansion of a Green function in separable coordinates we turn to the systematic construction of such expansions from first principles. A Green function for a potential problem satisfies the equation

$$\nabla_x^2 G(\mathbf{x}, \mathbf{x}') = -4\pi \delta(\mathbf{x} - \mathbf{x}') \quad (3.116)$$

subject to the boundary conditions $G(\mathbf{x}, \mathbf{x}') = 0$ for either \mathbf{x} or \mathbf{x}' on the boundary surface S . For spherical boundary surfaces we desire an expansion of the general form (3.114). Accordingly we exploit the fact that the delta function can be written*

$$\delta(\mathbf{x} - \mathbf{x}') = \frac{1}{r^2} \delta(r - r') \delta(\phi - \phi') \delta(\cos \theta - \cos \theta')$$

and that the completeness relation (3.56) can be used to represent the angular delta functions:

$$\delta(\mathbf{x} - \mathbf{x}') = \frac{1}{r^2} \delta(r - r') \sum_{l=0}^{\infty} \sum_{m=-l}^l Y_{lm}^*(\theta', \phi') Y_{lm}(\theta, \phi) \quad (3.117)$$

Then the Green function, considered as a function of \mathbf{x} , can be expanded as

$$G(\mathbf{x}, \mathbf{x}') = \sum_{l=0}^{\infty} \sum_{m=-l}^l A_{lm}(r | r', \theta', \phi') Y_{lm}(\theta, \phi) \quad (3.118)$$

* To express $\delta(\mathbf{x} - \mathbf{x}') = \delta(x_1 - x'_1) \delta(x_2 - x'_2) \delta(x_3 - x'_3)$ in terms of the coordinates (ξ_1, ξ_2, ξ_3) , related to (x_1, x_2, x_3) via the Jacobian $J(x_i, \xi_i)$, we note that the meaningful quantity is $\delta(\mathbf{x} - \mathbf{x}') d^3x$. Hence

$$\delta(\mathbf{x} - \mathbf{x}') = \frac{1}{|J(x_i, \xi_i)|} \delta(\xi_1 - \xi'_1) \delta(\xi_2 - \xi'_2) \delta(\xi_3 - \xi'_3)$$

Substitution of (3.117) and (3.118) into (3.116) leads to the results

$$A_{lm}(r | r', \theta', \phi') = g_l(r, r') Y_{lm}^*(\theta', \phi') \quad (3.119)$$

with

$$\frac{1}{r} \frac{d^2}{dr^2} (r g_l(r, r')) - \frac{l(l+1)}{r^2} g_l(r, r') = -\frac{4\pi}{r^2} \delta(r-r') \quad (3.120)$$

The radial Green function is seen to satisfy the homogeneous radial equation (3.7) for $r \neq r'$. Thus it can be written as:

$$g_l(r, r') = \begin{cases} A r^l + B r^{-(l+1)}, & \text{for } r < r' \\ A' r^l + B' r^{-(l+1)}, & \text{for } r > r' \end{cases}$$

The coefficients A, B, A', B' are functions of r' to be determined by the boundary conditions, the requirement implied by $\delta(r-r')$ in (3.120), and the symmetry of $g_l(r, r')$ in r and r' . Suppose that the boundary surfaces are concentric spheres at $r=a$ and $r=b$. The vanishing of $G(\mathbf{x}, \mathbf{x}')$ for \mathbf{x} on the surface implies the vanishing of $g_l(r, r')$ for $r=a$ and $r=b$. Consequently $g_l(r, r')$ becomes

$$g_l(r, r') = \begin{cases} A \left(r^l - \frac{a^{2l+1}}{r^{l+1}} \right), & r < r' \\ B' \left(\frac{1}{r^{l+1}} - \frac{r^l}{b^{2l+1}} \right), & r > r' \end{cases} \quad (3.121)$$

The symmetry in r and r' requires that the coefficients $A(r')$ and $B'(r')$ be such that $g_l(r, r')$ can be written

$$g_l(r, r') = C \left(r_{<}^l - \frac{a^{2l+1}}{r_{<}^{l+1}} \right) \left(\frac{1}{r_{>}^{l+1}} - \frac{r_{>}^l}{b^{2l+1}} \right) \quad (3.122)$$

where $r_{<}$ ($r_{>}$) is the smaller (larger) of r and r' . To determine the constant C we must consider the effect of the delta function in (3.120). If we multiply both sides of (3.120) by r and integrate over the interval from $r=r'-\epsilon$ to $r=r'+\epsilon$, where ϵ is very small, we obtain

$$\left\{ \frac{d}{dr} [r g_l(r, r')] \right\}_{r'+\epsilon} - \left\{ \frac{d}{dr} [r g_l(r, r')] \right\}_{r'-\epsilon} = -\frac{4\pi}{r'} \quad (3.123)$$

Thus there is a discontinuity in slope at $r=r'$, as indicated in Fig. 3.10.

For $r=r'+\epsilon$, $r_{>}=r$, $r_{<}=r'$. Hence

$$\begin{aligned} \left\{ \frac{d}{dr} [r g_l(r, r')] \right\}_{r'+\epsilon} &= C \left(r'^l - \frac{a^{2l+1}}{r'^{l+1}} \right) \left[\frac{d}{dr} \left(\frac{1}{r^{l+1}} - \frac{r^l}{b^{2l+1}} \right) \right]_{r=r'} \\ &= -\frac{C}{r'} \left[1 - \left(\frac{a}{r'} \right)^{2l+1} \right] \left[l + (l+1) \left(\frac{r'}{b} \right)^{2l+1} \right] \end{aligned}$$

Similarly

$$\left\{ \frac{d}{dr} [r g_l(r, r')] \right\}_{r'-\epsilon} = \frac{C}{r'} \left[l + 1 + l \left(\frac{a}{r'} \right)^{2l+1} \right] \left[1 - \left(\frac{r'}{b} \right)^{2l+1} \right]$$

Fig. 3.10 Discontinuity in slope of the radial Green function.

Substituting these derivatives into (3.123), we find:

$$C = \frac{4\pi}{(2l+1) \left[1 - \left(\frac{a}{b} \right)^{2l+1} \right]} \quad (3.124)$$

Combination of (3.124), (3.122), (3.119), and (3.118) yields the expansion of the Green function for a spherical shell bounded by $r=a$ and $r=b$:

$$G(\mathbf{x}, \mathbf{x}') = 4\pi \sum_{l=0}^{\infty} \sum_{m=-l}^l \frac{Y_{lm}^*(\theta', \phi') Y_{lm}(\theta, \phi)}{(2l+1) \left[1 - \left(\frac{a}{b} \right)^{2l+1} \right]} \left(r_{<}^l - \frac{a^{2l+1}}{r_{<}^{l+1}} \right) \left(\frac{1}{r_{>}^{l+1}} - \frac{r_{>}^l}{b^{2l+1}} \right) \quad (3.125)$$

For the special cases $a \rightarrow 0$, $b \rightarrow \infty$, and $b \rightarrow \infty$, we recover the previous expansions (3.70) and (3.114), respectively. For the “interior” problem with a sphere of radius b we merely let $a \rightarrow 0$. Whereas the expansion for a single sphere is most easily obtained from the image solution, the general result (3.125) for a spherical shell is rather difficult to obtain by the method of images, since it involves an infinite set of images.

3.10 Solution of Potential Problems with the Spherical Green Function Expansion

The general solution to the Poisson equation with specified values of the potential on the boundary surface is (see Section 1.10):

$$\Phi(\mathbf{x}) = \int_V \rho(\mathbf{x}') G(\mathbf{x}, \mathbf{x}') d^3x' - \frac{1}{4\pi} \oint_S \Phi(\mathbf{x}') \frac{\partial G}{\partial n'} da' \quad (3.126)$$

For purposes of illustration let us consider the potential *inside* a sphere of radius b . First we will establish the equivalence of the surface integral in (3.126) to the previous method of Section 3.5, equations (3.61) and (3.58). With $a=0$ in

(3.125), the normal derivative, evaluated at $r' = b$, is:

$$\frac{\partial G}{\partial n'} = \frac{\partial G}{\partial r'} \bigg|_{r'=b} = -\frac{4\pi}{b^2} \sum_{l,m} \left(\frac{r}{b}\right)^l Y_{lm}^*(\theta', \phi') Y_{lm}(\theta, \phi) \quad (3.127)$$

Consequently the solution of the Laplace equation inside $r = b$ with $\Phi = V(\theta', \phi')$ on the surface is, according to (3.126):

$$\Phi(\mathbf{x}) = \sum_{l,m} \left[\int V(\theta', \phi') Y_{lm}^*(\theta', \phi') d\Omega' \right] \left(\frac{r}{b}\right)^l Y_{lm}(\theta, \phi) \quad (3.128)$$

For the case considered, this is the same form of solution as (3.61) with (3.58). There is a *third* form of solution for the sphere, the so-called Poisson integral (2.19). The equivalence of this solution to the Green function expansion solution is implied by the fact that both were derived from the general expression (3.126) and the image Green function. The explicit demonstration of the equivalence of (2.19) and the series solution (3.61) will be left to the problems.

We now turn to the solution of problems with charge distributed in the volume, so that the volume integral in (3.126) is involved. It is sufficient to consider problems in which the potential vanishes on the boundary surfaces. By linear superposition of a solution of the Laplace equation the general situation can be obtained. The first illustration is that of a hollow grounded sphere of radius b with a concentric ring of charge of radius a and total charge Q . The ring of charge is located in the x - y plane, as shown in Fig. 3.11. The charge density of the ring can be written with the help of delta functions in angle and radius as

$$\rho(\mathbf{x}') = \frac{Q}{2\pi a^2} \delta(r' - a) \delta(\cos \theta') \quad (3.129)$$

In the volume integral over the Green function only terms in (3.125) with $m = 0$

Fig. 3.11 Ring of charge of radius a and total charge Q inside a grounded, conducting sphere of radius b .

will survive because of azimuthal symmetry. Then, using (3.57) and remembering that $a \rightarrow 0$ in (3.125), we find

$$\begin{aligned}\Phi(\mathbf{x}) &= \int \rho(\mathbf{x}') G(\mathbf{x}, \mathbf{x}') d^3x' \\ &= Q \sum_{l=0}^{\infty} P_l(0) r_{<}^l \left(\frac{1}{r_{>}^{l+1}} - \frac{r_{>}^l}{b^{2l+1}} \right) P_l(\cos \theta)\end{aligned}\quad (3.130)$$

where now $r_{<}$ ($r_{>}$) is the smaller (larger) of r and a . Using the fact that $P_{2n+1}(0) = 0$ and $P_{2n}(0) = \frac{(-1)^n (2n-1)!!}{2^n n!}$, (3.130) can be written as:

$$\Phi(\mathbf{x}) = Q \sum_{n=0}^{\infty} \frac{(-1)^n (2n-1)!!}{2^n n!} r_{<}^{2n} \left(\frac{1}{r_{>}^{2n+1}} - \frac{r_{>}^{2n}}{b^{4n+1}} \right) P_{2n}(\cos \theta) \quad (3.131)$$

In the limit $b \rightarrow \infty$, it will be seen that (3.130) or (3.131) reduces to the expression at the end of Section 3.3 for a ring of charge in free space. The present result can be obtained alternatively by using that result and the images for a sphere.

A second example of charge densities, illustrated in Fig. 3.12, is that of a hollow grounded sphere with a uniform line charge of total charge Q located on the z axis between the north and south poles of the sphere. Again with the help of delta functions the volume-charge density can be written:

$$\rho(\mathbf{x}') = \frac{Q}{2b} \frac{1}{2\pi r'^2} [\delta(\cos \theta' - 1) + \delta(\cos \theta' + 1)] \quad (3.132)$$

The two delta functions in $\cos \theta$ correspond to the two halves of the line charge, above and below the x - y plane. The factor $2\pi r'^2$ in the denominator assures that the charge density has a constant *linear* density $Q/2b$. With this density in

Fig. 3.12 Uniform line charge of length $2b$ and total charge Q inside a grounded, conducting sphere of radius b .

(3.126) we obtain

$$\Phi(\mathbf{x}) = \frac{Q}{2b} \sum_{l=0}^{\infty} [P_l(1) + P_l(-1)] P_l(\cos \theta) \int_0^b r^l \left(\frac{1}{r^{l+1}} - \frac{r^l}{b^{2l+1}} \right) dr' \quad (3.133)$$

The integral must be broken up into the intervals $0 \leq r' < r$ and $r \leq r' \leq b$. Then we find

$$\begin{aligned} \int_0^b &= \left(\frac{1}{r^{l+1}} - \frac{r^l}{b^{2l+1}} \right) \int_0^r r'^l dr' + r^l \int_r^b \left(\frac{1}{r'^{l+1}} - \frac{r^l}{b^{2l+1}} \right) dr' \\ &= \frac{(2l+1)}{l(l+1)} \left[1 - \left(\frac{r}{b} \right)^l \right] \end{aligned} \quad (3.134)$$

For $l=0$ this result is indeterminate. Applying L'Hospital's rule, we have, for $l=0$ only,

$$\int_0^b = \lim_{l \rightarrow 0} \frac{\frac{d}{dl} \left[1 - \left(\frac{r}{b} \right)^l \right]}{\frac{d}{dl} (l)} = \lim_{l \rightarrow 0} \left[-\frac{d}{dl} e^{l \ln(r/b)} \right] = \ln \left(\frac{b}{r} \right) \quad (3.135)$$

This can be verified by direct integration in (3.133) for $l=0$. Using the fact that $P_l(-1) = (-1)^l$, the potential (3.133) can be put in the form:

$$\Phi(\mathbf{x}) = \frac{Q}{b} \left\{ \ln \left(\frac{b}{r} \right) + \sum_{j=1}^{\infty} \frac{(4j+1)}{2j(2j+1)} \left[1 - \left(\frac{r}{b} \right)^{2j} \right] P_{2j}(\cos \theta) \right\} \quad (3.136)$$

The presence of the logarithm for $l=0$ reminds us that the potential diverges along the z axis. This is borne out by the series in (3.136), which diverges for $\cos \theta = \pm 1$, except at $r=b$ exactly.

The surface-charge density on the grounded sphere is readily obtained from (3.136) by differentiation:

$$\sigma(\theta) = \frac{1}{4\pi} \frac{\partial \Phi}{\partial r} \Big|_{r=b} = -\frac{Q}{4\pi b^2} \left[1 + \sum_{j=1}^{\infty} \frac{(4j+1)}{(2j+1)} P_{2j}(\cos \theta) \right] \quad (3.137)$$

The leading term shows that the total charge induced on the sphere is $-Q$, the other terms integrating to zero over the surface of the sphere.

3.11 Expansion of Green Functions in Cylindrical Coordinates

The expansion of the potential of a unit point charge in cylindrical coordinates affords another useful example of Green function expansions. We will present the initial steps in general enough fashion that the procedure can be readily adapted to finding Green functions for potential problems with cylindrical boundary surfaces. The starting point is the equation for the Green function:

$$\nabla_x^2 G(\mathbf{x}, \mathbf{x}') = -\frac{4\pi}{\rho} \delta(\rho - \rho') \delta(\phi - \phi') \delta(z - z') \quad (3.138)$$

Where the delta function has been expressed in cylindrical coordinates. The ϕ and z delta functions can be written in terms of orthonormal functions:

$$\left. \begin{aligned} \delta(z-z') &= \frac{1}{2\pi} \int_{-\infty}^{\infty} dk e^{ik(z-z')} = \frac{1}{\pi} \int_0^{\infty} dk \cos[k(z-z')] \\ \delta(\phi-\phi') &= \frac{1}{2\pi} \sum_{m=-\infty}^{\infty} e^{im(\phi-\phi')} \end{aligned} \right\} \quad (3.139)$$

We expand the Green function in similar fashion:

$$G(\mathbf{x}, \mathbf{x}') = \frac{1}{2\pi^2} \sum_{m=-\infty}^{\infty} \int_0^{\infty} dk e^{im(\phi-\phi')} \cos[k(z-z')] g_m(k, \rho, \rho') \quad (3.140)$$

Then substitution into (3.138) leads to an equation for the radial Green function $g_m(k, \rho, \rho')$:

$$\frac{1}{\rho} \frac{d}{d\rho} \left(\rho \frac{dg_m}{d\rho} \right) - \left(k^2 + \frac{m^2}{\rho^2} \right) g_m = -\frac{4\pi}{\rho} \delta(\rho - \rho') \quad (3.141)$$

For $\rho \neq \rho'$ this is just equation (3.98) for the modified Bessel functions, $I_m(k\rho)$ and $K_m(k\rho)$. Suppose that $\psi_1(k\rho)$ is some linear combination of I_m and K_m which satisfies the correct boundary conditions for $\rho < \rho'$, and that $\psi_2(k\rho)$ is a linearly independent combination which satisfies the proper boundary conditions for $\rho > \rho'$. Then the symmetry of the Green function in ρ and ρ' requires that

$$g_m(k, \rho, \rho') = \psi_1(k\rho_{<}) \psi_2(k\rho_{>}) \quad (3.142)$$

The normalization of the product $\psi_1 \psi_2$ is determined by the discontinuity in slope implied by the delta function in (3.141):

$$\left. \frac{dg_m}{d\rho} \right|_+ - \left. \frac{dg_m}{d\rho} \right|_- = -\frac{4\pi}{\rho'} \quad (3.143)$$

where $|_{\pm}$ means evaluated at $\rho = \rho' \pm \epsilon$. From (3.142) it is evident that

$$\left[\left. \frac{dg_m}{d\rho} \right|_+ - \left. \frac{dg_m}{d\rho} \right|_- \right] = k(\psi_1 \psi_2' - \psi_2 \psi_1') = kW[\psi_1, \psi_2] \quad (3.144)$$

where primes mean differentiation with respect to the argument, and $W[\psi_1, \psi_2]$ is the Wronskian of ψ_1 and ψ_2 . Equation (3.141) is of the Sturm-Liouville type

$$\frac{d}{dx} \left[p(x) \frac{dy}{dx} \right] + g(x)y = 0 \quad (3.145)$$

and it is well known that the Wronskian of two linearly independent solutions of such an equation is proportional to $[1/p(x)]$. Hence the possibility of satisfying (3.143) for all values of ρ' is assured. Clearly we must demand that the normalization of the product $\psi_1 \psi_2$ is such that the Wronskian has the value:

$$W[\psi_1(x), \psi_2(x)] = -\frac{4\pi}{x} \quad (3.146)$$

If there are no boundary surfaces, the requirement is that $g_m(k, \rho, \rho')$ be finite at $\rho=0$ and vanish at $\rho \rightarrow \infty$. Consequently $\psi_1(k\rho) = A I_m(k\rho)$ and $\psi_2(k\rho) = K_m(k\rho)$. The constant A is to be determined from the Wronskian condition (3.146). Since the Wronskian is proportional to $(1/x)$ for all values of x , it does not matter where we evaluate it. Using the limiting forms (3.102) and (3.103) for small x [or (3.104) for large x], we find

$$W[I_m(x), K_m(x)] = -\frac{1}{x} \quad (3.147)$$

so that $A = 4\pi$. The expansion of $1/|\mathbf{x} - \mathbf{x}'|$ therefore becomes:

$$\frac{1}{|\mathbf{x} - \mathbf{x}'|} = \frac{2}{\pi} \sum_{m=-\infty}^{\infty} \int_0^{\infty} dk e^{im(\phi - \phi')} \cos[k(z - z')] I_m(k\rho_{<}) K_m(k\rho_{>}) \quad (3.148)$$

This can also be written entirely in terms of real functions as:

$$\begin{aligned} \frac{1}{|\mathbf{x} - \mathbf{x}'|} &= \frac{4}{\pi} \int_0^{\infty} dk \cos[k(z - z')] \\ &\times \left\{ \frac{1}{2} I_0(k\rho_{<}) K_0(k\rho_{>}) + \sum_{m=1}^{\infty} \cos[m(\phi - \phi')] I_m(k\rho_{<}) K_m(k\rho_{>}) \right\} \quad (3.149) \end{aligned}$$

A number of useful mathematical results can be obtained from this expansion. If we let $\mathbf{x}' \rightarrow 0$, only the $m=0$ term survives, and we obtain the integral representation:

$$\frac{1}{\sqrt{\rho^2 + z^2}} = \frac{2}{\pi} \int_0^{\infty} \cos kz K_0(k\rho) dk \quad (3.150)$$

If we replace ρ^2 in (3.150) by $R^2 = \rho^2 + \rho'^2 - 2\rho\rho' \cos(\phi - \phi')$, then we have on the left-hand side the inverse distance $|\mathbf{x} - \mathbf{x}'|^{-1}$ with $z' = 0$, i.e., just (3.149) with $z' = 0$. Then comparison of the right-hand sides of (3.149) and (3.150) (which must hold for *all* values of z) leads to the identification:

$$\begin{aligned} K_0(k\sqrt{\rho^2 + \rho'^2 - 2\rho\rho' \cos(\phi - \phi')}) \\ = I_0(k\rho_{<}) K_0(k\rho_{>}) + 2 \sum_{m=1}^{\infty} \cos[m(\phi - \phi')] I_m(k\rho_{<}) K_m(k\rho_{>}) \quad (3.151) \end{aligned}$$

In this last result we can take the limit $k \rightarrow 0$ and obtain an expansion for the Green function for (two-dimensional) polar coordinates:

$$\ln \left(\frac{1}{\sqrt{\rho^2 + \rho'^2 - 2\rho\rho' \cos(\phi - \phi')}} \right) = \ln \left(\frac{1}{\rho_{>}} \right) + \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{\rho_{<}}{\rho_{>}} \right)^m \cos[m(\phi - \phi')] \quad (3.152)$$

This representation can be verified by a systematic construction of the two-dimensional Green function for the Poisson equation along the lines leading to (3.148).

3.12 Eigenfunction Expansions for Green Functions

Another technique for obtaining expansions of Green functions is the use of eigenfunctions for some related problem. This approach is intimately connected with the methods of Sections 3.9 and 3.11.

To specify what we mean by eigenfunctions, we consider an elliptic differential equation of the form:

$$\nabla^2 \psi(\mathbf{x}) + [f(\mathbf{x}) + \lambda] \psi(\mathbf{x}) = 0 \quad (3.153)$$

If the solutions $\psi(\mathbf{x})$ are required to satisfy homogeneous boundary conditions on the surface S of the volume of interest V , then (3.153) will not in general have well-behaved (e.g., finite and continuous) solutions, except for certain values of λ . These values of λ , denoted by λ_n , are called *eigenvalues* (or *characteristic values*) and the solutions $\psi_n(\mathbf{x})$ are called *eigenfunctions*.* The eigenvalue differential equation is written:

$$\nabla^2 \psi_n(\mathbf{x}) + [f(\mathbf{x}) + \lambda_n] \psi_n(\mathbf{x}) = 0 \quad (3.154)$$

By methods similar to those used to prove the orthogonality of the Legendre or Bessel functions it can be shown that the eigenfunctions are orthogonal:

$$\int_V \psi_m^*(\mathbf{x}) \psi_n(\mathbf{x}) d^3x = \delta_{mn} \quad (3.155)$$

where the eigenfunctions are assumed normalized. The spectrum of eigenvalues λ_n may be a discrete set, or a continuum, or both. It will be assumed that the totality of eigenfunctions forms a complete set.

Suppose now that we wish to find the Green function for the equation:

$$\nabla_x^2 G(\mathbf{x}, \mathbf{x}') + [f(\mathbf{x}) + \lambda] G(\mathbf{x}, \mathbf{x}') = -4\pi \delta(\mathbf{x} - \mathbf{x}') \quad (3.156)$$

where λ is *not* equal to one of the eigenvalues λ_n of (3.154). Furthermore, suppose that the Green function is to have the same boundary conditions as the eigenfunctions of (3.154). Then the Green function can be expanded in a series of the eigenfunctions of the form:

$$G(\mathbf{x}, \mathbf{x}') = \sum_n a_n(\mathbf{x}') \psi_n(\mathbf{x}) \quad (3.157)$$

Substitution into the differential equation for the Green function leads to the result:

$$\sum_m a_m(\mathbf{x}') (\lambda - \lambda_m) \psi_m(\mathbf{x}) = -4\pi \delta(\mathbf{x} - \mathbf{x}') \quad (3.158)$$

* The reader familiar with wave mechanics will recognize (3.153) as equivalent to the Schrödinger equation for a particle in a potential.

If we multiply both sides by $\psi_n^*(\mathbf{x})$ and integrate over the volume V , the orthogonality condition (3.155) reduces the left-hand side to one term, and we find:

$$a_n(\mathbf{x}') = 4\pi \frac{\psi_n^*(\mathbf{x}')}{\lambda_n - \lambda} \quad (3.159)$$

Consequently the eigenfunction expansion of the Green function is:

$$G(\mathbf{x}, \mathbf{x}') = 4\pi \sum_n \frac{\psi_n^*(\mathbf{x}')\psi_n(\mathbf{x})}{\lambda_n - \lambda} \quad (3.160)$$

For a continuous spectrum the sum is replaced by an integral.

Specializing the above considerations to the Poisson equation, we place $f(\mathbf{x})=0$ and $\lambda=0$ in (3.156). As a first, essentially trivial, illustration we let (3.154) be the wave equation over all space:

$$(\nabla^2 + k^2)\psi_{\mathbf{k}}(\mathbf{x}) = 0 \quad (3.161)$$

with the continuum of eigenvalues, k^2 , and the eigenfunctions:

$$\psi_{\mathbf{k}}(\mathbf{x}) = \frac{1}{(2\pi)^{3/2}} e^{i\mathbf{k}\cdot\mathbf{x}} \quad (3.162)$$

These eigenfunctions have delta function normalization:

$$\int \psi_{\mathbf{k}}^*(\mathbf{x})\psi_{\mathbf{k}'}(\mathbf{x}) d^3x = \delta(\mathbf{k}-\mathbf{k}') \quad (3.163)$$

Then, according to (3.160), the infinite space Green function has the expansion:

$$\frac{1}{|\mathbf{x}-\mathbf{x}'|} = \frac{1}{2\pi^2} \int d^3k \frac{e^{i\mathbf{k}\cdot(\mathbf{x}-\mathbf{x}')}}{k^2} \quad (3.164)$$

This is just the three-dimensional Fourier integral representation of $1/|\mathbf{x}-\mathbf{x}'|$.

As a second example, consider the Green function for a Dirichlet problem inside a rectangular box defined by the six planes, $x=0$, $y=0$, $z=0$, $x=a$, $y=b$, $z=c$. The expansion is to be made in terms of eigenfunctions of the wave equation:

$$(\nabla^2 + k_{lmn}^2)\psi_{lmn}(x, y, z) = 0 \quad (3.165)$$

where the eigenfunctions which vanish on all the boundary surfaces are

$$\left. \begin{aligned} \psi_{lmn}(x, y, z) &= \sqrt{\frac{8}{abc}} \sin\left(\frac{l\pi x}{a}\right) \sin\left(\frac{m\pi y}{b}\right) \sin\left(\frac{n\pi z}{c}\right) \\ \text{and} \quad k_{lmn}^2 &= \pi^2 \left(\frac{l^2}{a^2} + \frac{m^2}{b^2} + \frac{n^2}{c^2} \right) \end{aligned} \right\} \quad (3.166)$$

The expansion of the Green function is therefore:

$$G(\mathbf{x}, \mathbf{x}') = \frac{32}{\pi abc} \times \sum_{l,m,n=1}^{\infty} \frac{\sin\left(\frac{l\pi x}{a}\right) \sin\left(\frac{l\pi x'}{a}\right) \sin\left(\frac{m\pi y}{b}\right) \sin\left(\frac{m\pi y'}{b}\right) \sin\left(\frac{n\pi z}{c}\right) \sin\left(\frac{n\pi z'}{c}\right)}{\left(\frac{l^2}{a^2} + \frac{m^2}{b^2} + \frac{n^2}{c^2}\right)} \quad (3.167)$$

To relate expansion (3.167) to the type of expansions obtained in Sections 3.9 and 3.11, namely, (3.125) for spherical coordinates and (3.148) for cylindrical coordinates, we write down the analogous expansion for the rectangular box. If the x and y coordinates are treated in the manner of (θ, ϕ) or (ϕ, z) in those cases, while the z coordinate is singled out for special treatment, we obtain the Green function:

$$G(\mathbf{x}, \mathbf{x}') = \frac{16\pi}{ab} \sum_{l,m=1}^{\infty} \sin\left(\frac{l\pi x}{a}\right) \sin\left(\frac{l\pi x'}{a}\right) \sin\left(\frac{m\pi y}{b}\right) \sin\left(\frac{m\pi y'}{b}\right) \times \left[\frac{\sinh(K_{lm}z) \sinh(K_{lm}(c-z))}{K_{lm} \sinh(K_{lm}c)} \right] \quad (3.168)$$

where $K_{lm} = \pi \left(\frac{l^2}{a^2} + \frac{m^2}{b^2} \right)^{1/2}$. If (3.167) and (3.168) are to be equal, it must be that the sum over n in (3.167) is just the Fourier series representation on the interval $(0, c)$ of the one-dimensional Green function in z in (3.168):

$$\frac{\sinh(K_{lm}z) \sinh(K_{lm}(c-z))}{K_{lm} \sinh(K_{lm}c)} = \frac{2}{c} \sum_{n=1}^{\infty} \frac{\sin\left(\frac{n\pi z'}{c}\right)}{K_{lm}^2 + \left(\frac{n\pi}{c}\right)^2} \sin\left(\frac{n\pi z}{c}\right) \quad (3.169)$$

The verification that (3.169) is the correct Fourier representation is left as an exercise for the reader.

Further illustrations of this technique will be found in the problems at the end of the chapter.

3.13 Mixed Boundary Conditions, Conducting Plane with a Circular Hole

The potential problems discussed so far in this chapter have been of the orthodox kind in which the boundary conditions are of one type (usually Dirichlet) over the whole boundary surface. In the uniqueness proof for solutions of the Laplace or Poisson equation (Section 1.9) it was pointed out, however, that mixed boundary conditions, where the potential is specified over part of the boundary and its normal derivative is specified over the remainder,

Fig. 3.13

also lead to well-defined, unique, boundary-value problems. There is a tendency in existing textbooks to mention the possibility of mixed boundary conditions when making the uniqueness proof and to ignore such problems in subsequent discussion. The reason, as we shall see, is that mixed boundary conditions are much more difficult to handle than the normal type.

To illustrate the difficulties encountered with mixed boundary conditions, we consider the problem of an infinitely thin, grounded, conducting plane with a circular hole of radius a cut in it, and with the electric field far from the hole being normal to the plane, constant in magnitude, and having different values on either side of the plane. The geometry is sketched in Fig. 3.13. The plane is at $z=0$; the hole is centered on the origin of coordinates; the nonvanishing asymptotic electric field components are $E_z = -E_0$ for $z > 0$ and $E_z = -E_1$ for $z < 0$. The problem may seem contrived, but with $E_0=0$ or $E_1=0$ it has application for radiation from small holes in the walls of wave guides, where “small” is defined as small compared to a wavelength so that electrostatic considerations can apply (see Section 9.5).

Since the electric field is specified far from the hole, we write the potential as

$$\Phi = \begin{cases} E_0 z + \Phi^{(1)} & (z > 0) \\ E_1 z + \Phi^{(1)} & (z < 0) \end{cases} \quad (3.170)$$

If the hole were not there, $\Phi^{(1)}$ would be zero. The top surface of the sheet would

have a uniform surface charge density $-E_0/4\pi$ and the bottom surface a charge density $E_1/4\pi$. The potential $\Phi^{(1)}$ can thus be thought of as resulting from a rearrangement of surface charge in the neighborhood of the hole. Since this charge density is located on the plane $z=0$, the potential $\Phi^{(1)}$ can be represented as

$$\Phi^{(1)}(x, y, z) = \int \frac{\sigma^{(1)}(x', y') dx' dy'}{\sqrt{(x-x')^2 + (y-y')^2 + z^2}}$$

This shows that $\Phi^{(1)}$ is *even* in z , so that $E_x^{(1)}$ and $E_y^{(1)}$ are even in z , but $E_z^{(1)}$ is *odd*. We note that $E_x^{(1)}$ and $E_y^{(1)}$ are the x and y components of the total electric field, but that, because of (3.170), $E_z^{(1)}$ is not the total z component. Thus, even though it is odd in z , it does not vanish at $z=0$. Rather, it is discontinuous there. Since the *total z component* of electric field must be continuous across $z=0$ in the hole, we must have

$$-E_0 + E_z^{(1)}|_{z=0^+} = -E_1 + E_z^{(1)}|_{z=0^-}$$

Because $E_z^{(1)}$ is odd in z , this relation determines the normal component of the electric field to be

$$E_z^{(1)}|_{z=0^+} = -E_z^{(1)}|_{z=0^-} = \frac{1}{2}(E_0 - E_1)$$

provided (x, y) lie inside the opening ($0 \leq \rho < a$). For points on the conducting surface ($a \leq \rho < \infty$), the electric field is not known, but the potential is zero by hypothesis. From (3.170) this means that $\Phi^{(1)} = 0$ there. Note that in the opening we do not know the potential. We therefore have an electrostatic boundary-value problem with the following *mixed boundary conditions*:

$$\text{and} \quad \left. \begin{aligned} \frac{\partial \Phi^{(1)}}{\partial z} \Big|_{z=0^+} &= -\frac{1}{2}(E_0 - E_1) & \text{for } 0 \leq \rho < a \\ \Phi^{(1)}|_{z=0} &= 0 & \text{for } a \leq \rho < \infty \end{aligned} \right\} \quad (3.171)$$

Because of the azimuthal symmetry of the geometry, the potential $\Phi^{(1)}$ can be written in terms of cylindrical coordinates [from (3.110)] as

$$\Phi^{(1)}(\rho, z) = \int_0^\infty dk A(k) e^{-k|z|} J_0(k\rho) \quad (3.172)$$

Before proceeding to see how $A(k)$ is determined by the boundary conditions, we relate $A(k)$ and its derivatives at $k=0$ to the asymptotic behavior of the potential. For large ρ or $|z|$ the rapid oscillations of $J_0(k\rho)$ or the rapid decrease of $e^{-k|z|}$ imply that the integral in (3.172) receives its important contributions from the region around $k=0$. The asymptotic behavior of $\Phi^{(1)}$ is therefore related to the behavior of $A(k)$ at small k . We assume that $A(k)$ can be expanded in a Taylor series around $k=0$:

$$A(k) = \sum_{l=0}^{\infty} \frac{k^l}{l!} \frac{d^l A}{dk^l}(0)$$

With this series inserted into (3.172), the potential $\Phi^{(1)}$ becomes

$$\Phi^{(1)}(\rho, z) = \sum_{l=0}^{\infty} \frac{d^l A}{dk^l}(0) B_l(\rho, z) \quad (3.173)$$

where

$$B_l(\rho, z) = \frac{1}{l!} \int_0^{\infty} dk k^l e^{-k|z|} J_0(k\rho) \quad (3.174)$$

The integral (3.174) can evidently be written

$$B_l = \frac{1}{l!} \left(-\frac{d}{d|z|} \right)^l \int_0^{\infty} dk e^{-k|z|} J_0(k\rho)$$

Using a result from Problem 3.14(c), we find that B_l is

$$B_l = \frac{1}{l!} \left(-\frac{d}{d|z|} \right)^l \left(\frac{1}{\sqrt{\rho^2 + z^2}} \right) \quad (3.175)$$

The reader should not be surprised to find that explicit calculation yields

$$B_l = \frac{P_l(|\cos \theta|)}{r^{l+1}} \quad (3.176)$$

where $\cos \theta = z/r$ and $r = \sqrt{\rho^2 + z^2}$. The asymptotic expansion (3.173) is thus an expansion of the spherical harmonic form (3.33):

$$\Phi^{(1)} = \sum_{l=0}^{\infty} \frac{d^l A}{dk^l}(0) \cdot \frac{P_l(|\cos \theta|)}{r^{l+1}} \quad (3.177)$$

As is discussed in the next chapter, this expansion in powers of r^{-1} is called a multipole expansion. The $l=0$ coefficient, $A(0)$, is the *total charge*. The $l=1$ coefficient, $dA(0)/dk$, is the *dipole moment* in the z -direction, and so on. Once the function $A(k)$ is known these quantities that describe the asymptotic behavior of the potential can be evaluated without explicit construction of the potential itself.

We are now ready to discuss the mixed boundary value problem. With the assumed form (3.172) for $\Phi^{(1)}$ the boundary conditions (3.171) become a pair of integral equations of the first kind for $A(k)$:

$$\left. \begin{aligned} \int_0^{\infty} dk k A(k) J_0(k\rho) &= \frac{1}{2}(E_0 - E_1) & \text{for } 0 \leq \rho < a \\ \int_0^{\infty} dk A(k) J_0(k\rho) &= 0 & \text{for } a \leq \rho < \infty \end{aligned} \right\} \quad (3.178)$$

Such pairs of integral equations, with one of the pair holding over one part of the range of the independent variable and the other over the other part of the range, are known as *dual integral equations*. The general theory of such integral

equations is complicated and not highly developed.* Just over a hundred years ago H. Weber solved the closely related problem of the potential of a charged circular disc by means of certain discontinuous integrals involving Bessel functions. We shall appeal to a generalization of Weber's formulas. Consider the dual integral equations,

$$\begin{aligned} \int_0^\infty dy \, yg(y)J_n(yx) &= x^n & \text{for } 0 \leq x < 1 \\ \int_0^\infty dy \, g(y)J_n(yx) &= 0 & \text{for } 1 \leq x < \infty \end{aligned} \quad (3.179)$$

Examination of the formula of Sonine and Schafheitlin for the integral of $J_\mu(at)J_\nu(bt)t^{-\lambda}$ [see Watson pp. 398 ff, or Magnus and Oberhettinger, p. 35, Eqs. (S₁) and (S₃)] shows that the solution for $g(y)$ is

$$g(y) = \frac{\Gamma(n+1)}{\sqrt{\pi} \Gamma(n+\frac{3}{2})} j_{n+1}(y) = \frac{\Gamma(n+1)}{\Gamma(n+\frac{3}{2})} \frac{J_{n+\frac{3}{2}}(y)}{(2y)^{1/2}} \quad (3.180)$$

In this relation $j_n(y)$ is the spherical Bessel function of order n (see Section 16.1).

For our pair of equations (3.178) we have $n=0$, $x=\rho/a$, $y=ka$. Therefore $A(k)$ is

$$A(k) = \frac{(E_0 - E_1)a^2}{\pi} j_1(ka) = \frac{(E_0 - E_1)}{\pi} \left[\frac{\sin ka}{k^2} - \frac{a \cos ka}{k} \right] \quad (3.181)$$

The expansion of $A(k)$ for small k takes the form,

$$A(k) \approx \frac{(E_0 - E_1)a^2}{3\pi} \left[ka - \frac{(ka)^3}{10} + \dots \right]$$

This means that total charge associated with $\Phi^{(1)}$ is zero and the leading term in the asymptotic potential (3.177) is the $l=1$ contribution,

$$\Phi^{(1)} \rightarrow \frac{(E_0 - E_1)a^3}{3\pi} \cdot \frac{|z|}{r^3} \quad (3.182)$$

falling off with distance as r^{-2} and having an effective electric dipole moment,

$$\mathbf{p} = \mp \frac{(\mathbf{E}_0 - \mathbf{E}_1)a^3}{3\pi} \quad (z \gtrless 0) \quad (3.183)$$

The reversal of the effective dipole moment depending on whether the observation point is above or below the plane is a consequence of the fact that a true dipole potential is odd in z , whereas (3.182) is even. The idea that a small hole in a plane conducting sheet is equivalent far from the opening to a dipole normal to

* One recent monograph, I. N. Sneddon, *Mixed Boundary Value Problems in Potential Theory*, North-Holland, Amsterdam and Wiley-Interscience, New York (1966), is devoted to our subject. See also Tranter, p. 50 and Chapter VIII.

the surface is important in discussing the consequences of such openings in the walls of wave guides and cavities. Figure 9.4 shows in pictorial form the origin of the dipole-like field as a consequence of the penetration of the field lines through the hole to terminate on the side with the smaller constant field. The picture is given quantitative meaning through (3.182) and (3.183).

The added potential $\Phi^{(1)}$ in the neighborhood of the opening must be calculated from the exact expression,

$$\Phi^{(1)}(\rho, z) = \frac{(E_0 - E_1)}{\pi} a^2 \int_0^\infty dk j_1(ka) e^{-k|z|} J_0(k\rho) \quad (3.184)$$

We content ourselves with some special cases. The added potential on the axis ($\rho=0$) is*

$$\Phi^{(1)}(0, z) = \frac{(E_0 - E_1)a}{\pi} \left[1 - \frac{|z|}{a} \tan^{-1} \left(\frac{a}{|z|} \right) \right]$$

For $|z| \gg a$ this reduces to (3.182) with $r=|z|$, while for $|z| \rightarrow 0$ it is approximated by the first term. In the plane of the opening ($z=0$) the potential $\Phi^{(1)}$ is

$$\Phi^{(1)}(\rho, 0) = \frac{(E_0 - E_1)}{\pi} \sqrt{a^2 - \rho^2}$$

for $0 \leq \rho < a$ (and zero, of course, for $\rho \geq a$). The *tangential electric field in the opening* is a radial field,

$$\mathbf{E}_{\text{tan}}(\rho, 0) = \frac{(E_0 - E_1)}{\pi} \frac{\boldsymbol{\rho}}{\sqrt{a^2 - \rho^2}} \quad (3.185)$$

The *normal component* of electric field in the opening is, from the first equation in (3.171), just the average of the uniform fields above and below the plane, that is,

$$E_z(\rho, 0) = -\frac{1}{2}(E_0 + E_1) \quad (3.186)$$

We note that the magnitude of the electric field has a square root singularity at the edge of the opening, in agreement with the considerations of Section 2.11. The surface charge densities on the upper and lower sides of the conducting plane in the neighborhood of the hole can be evaluated in a straightforward manner. The explicit calculation is left to the problems.

Equipotential contours near the circular hole for the full potential (3.170) are shown in Fig. 3.14 for the situation where $E_1=0$. At distances more than two or three times the radius away from the hole its presence is hardly discernible.

The classic problem of a charged conducting disc is discussed in detail by Sneddon (*op. cit.*). The mixed boundary conditions for the disc or hole can be

* For integrals of the kind encountered here, see Watson, Chapter 13, Gradshteyn and Ryzhik, Magnus, Oberhettinger, and Soni, or the Bateman Manuscript Project.

Fig. 3.14 Equipotential contours near a circular hole in a conducting plane with a normal electric field E_0 far from the hole on one side and no field asymptotically on the other ($E_1=0$). The numbers are the values of the potential Φ in units of aE_0 . The distribution is rotationally symmetric about the vertical dashed line through the center of the hole.

avoided by separating the Laplace equation in elliptic coordinates. The disc (or hole) is then taken to be the limiting form of an oblate spheroidal surface. For this approach, see, for example, *Smythe*, pp. 124, 171, or *Jeans*, p. 244.

REFERENCES AND SUGGESTED READING

The subjects of the special functions of mathematical physics, the solution of ordinary differential equations, hypergeometric functions, and Sturm-Liouville theory are covered in many books. For the reader who does not already have his favorite, some of the possibilities are

PROBLEMS

- 3.1** Two concentric spheres have radii a , b ($b > a$) and are each divided into two hemispheres by the same horizontal plane. The upper hemisphere of the inner sphere and the lower hemisphere of the outer sphere are maintained at potential V . The other hemispheres are at zero potential

Determine the potential in the region $a \leq r \leq b$ as a series in Legendre polynomials. Include terms at least up to $l=4$. Check your solution against known results in the limiting cases $b \rightarrow \infty$, and $a \rightarrow 0$.

- 3.2** A spherical surface of radius R has charge uniformly distributed over its surface with a density $Q/4\pi R^2$, except for a spherical cap at the north pole, defined by the cone $\theta = \alpha$.

(a) Show that the potential inside the spherical surface can be expressed as

$$\Phi = \frac{Q}{2} \sum_{l=0}^{\infty} \frac{1}{2l+1} [P_{l+1}(\cos \alpha) - P_{l-1}(\cos \alpha)] \frac{r^l}{R^{l+1}} P_l(\cos \theta)$$

where, for $l=0$, $P_{-1}(\cos \alpha) = -1$. What is the potential outside?

(b) Find the magnitude and the direction of the electric field at the origin.

(c) Discuss the limiting forms of the potential (a) and electric field (b) as the spherical cap becomes (1) very small, and (2) so large that the area with charge on it becomes a very small cap at the south pole.

- 3.3** A thin, flat, conducting, circular disc of radius R is located in the x - y plane with its center at the origin, and is maintained at a fixed potential V . With the information that the charge density on a disc at fixed potential is proportional to $(R^2 - \rho^2)^{-1/2}$, where ρ is the distance out from the center of the disc,

(a) show that for $r > R$ the potential is

$$\Phi(r, \theta, \phi) = \frac{2VR}{\pi} \sum_{l=0}^{\infty} \frac{(-1)^l}{2l+1} \left(\frac{R}{r}\right)^{2l} P_{2l}(\cos \theta)$$

(b) find the potential for $r < R$.

(c) What is the capacitance of the disc?

- 3.4** The surface of a hollow conducting sphere of inner radius a is divided into an *even number* of equal segments by a set of planes whose common line of intersection is the z axis and which are distributed uniformly in the angle ϕ . (The segments are like the skin

on wedges of an apple, or the earth's surface between successive meridians of longitude.) The segments are kept at fixed potentials $\pm V$, alternately.

(a) Set up a series representation for the potential inside the sphere for the general case of $2n$ segments, and carry the calculation of the coefficients in the series far enough to determine exactly which coefficients are different from zero. For the nonvanishing terms, exhibit the coefficients as an integral over $\cos \theta$.

(b) For the special case of $n=1$ (two hemispheres) determine explicitly the potential up to and including all terms with $l=3$. By a coordinate transformation verify that this reduces to result (3.36) of Section 3.3.

- 3.5 A hollow sphere of inner radius a has the potential specified on its surface to be $\Phi = V(\theta, \phi)$. Prove the equivalence of the two forms of solution for the potential inside the sphere:

$$(a) \quad \Phi(\mathbf{x}) = \frac{a(a^2 - r^2)}{4\pi} \int \frac{V(\theta', \phi')}{(r^2 + a^2 - 2ar \cos \gamma)^{3/2}} d\Omega'$$

where $\cos \gamma = \cos \theta \cos \theta' + \sin \theta \sin \theta' \cos(\phi - \phi')$.

$$(b) \quad \Phi(\mathbf{x}) = \sum_{l=0}^{\infty} \sum_{m=-l}^l A_{lm} \left(\frac{r}{a}\right)^l Y_{lm}(\theta, \phi)$$

where $A_{lm} = \int d\Omega' Y_{lm}^*(\theta', \phi') V(\theta', \phi')$.

- 3.6 Two point charges q and $-q$ are located on the z axis at $z=+a$ and $z=-a$, respectively.

(a) Find the electrostatic potential as an expansion in spherical harmonics and powers of r for both $r > a$ and $r < a$.

(b) Keeping the product $qa \equiv p/2$ constant, take the limit of $a \rightarrow 0$ and find the potential for $r \neq 0$. This is by definition a dipole along the z axis and its potential.

(c) Suppose now that the dipole of part (b) is surrounded by a grounded spherical shell of radius b concentric with the origin. By linear superposition find the potential everywhere inside the shell.

- 3.7 Three point charges ($q, -2q, q$) are located in a straight line with separation a and with the middle charge ($-2q$) at the origin of a grounded conducting spherical shell of radius b , as indicated in the sketch.

Problem 3.7

(a) Write down the potential of the three charges in the absence of the grounded sphere. Find the limiting form of the potential as $a \rightarrow 0$, but the product $qa^2 = Q$ remains finite. Write this latter answer in spherical coordinates.

(b) The presence of the grounded sphere of radius b alters the potential for $r < b$. The added potential can be viewed as caused by the surface charge density induced on the inner surface at $r = b$ or by image charges located at $r > b$. Use linear superposition to satisfy the boundary conditions and find the potential everywhere inside the sphere for $r < a$ and $r > a$. Show that in the limit $a \rightarrow 0$,

$$\Phi(r, \theta, \phi) \rightarrow \frac{2Q}{r^3} \left(1 - \frac{r^5}{b^5}\right) P_2(\cos \theta)$$

3.8 A hollow right circular cylinder of radius b has its axis coincident with the z axis and its ends at $z = 0$ and $z = L$. The potential on the end faces is zero, while the potential on the cylindrical surface is given as $V(\phi, z)$. Using the appropriate separation of variables in cylindrical coordinates, find a series solution for the potential anywhere inside the cylinder.

3.9 For the cylinder in Problem 3.8 the cylindrical surface is made of two equal half-cylinders, one at potential V and the other at potential $-V$, so that

$$V(\phi, z) = \begin{cases} V & \text{for } -\frac{\pi}{2} < \phi < \frac{\pi}{2} \\ -V & \text{for } \frac{\pi}{2} < \phi < \frac{3\pi}{2} \end{cases}$$

(a) Find the potential inside the cylinder.

(b) Assuming $L \gg b$, consider the potential at $z = L/2$ as a function of ρ and ϕ and compare it with two-dimensional Problem 2.9.

3.10 Show that an arbitrary function $f(x)$ can be expanded on the interval $0 \leq x \leq a$ in a modified Fourier-Bessel series

$$f(x) = \sum_{n=1}^{\infty} A_n J_{\nu} \left(y_n \frac{x}{a} \right)$$

where y_n is the n th root $\frac{dJ_{\nu}(x)}{dx} = 0$, and the coefficients A_n are given by

$$A_n = \frac{2}{a^2 \left(1 - \frac{\nu^2}{y_n^2}\right) J_{\nu}^2(y_n)} \int_0^a f(x) x J_{\nu} \left(y_n \frac{x}{a} \right) dx$$

3.11 An infinite, thin, plane sheet of conducting material has a circular hole of radius a cut in it. A thin, flat disc of the same material and slightly smaller radius lies in the plane, filling the hole, but separated from the sheet by a very narrow insulating ring. The disc is maintained at a fixed potential V , while the infinite sheet is kept at zero potential.

(a) Using appropriate cylindrical coordinates, find an integral expression involving Bessel functions for the potential at any point above the plane.

(b) Show that the potential a perpendicular distance z above the center of the disc is

$$\Phi_0(z) = V \left(1 - \frac{z}{\sqrt{a^2 + z^2}} \right)$$

(c) Show that the potential a perpendicular distance z above the *edge* of the disc is

$$\Phi_a(z) = \frac{V}{2} \left[1 - \frac{kz}{\pi a} K(k) \right]$$

where $k = 2a/(z^2 + 4a^2)^{1/2}$, and $K(k)$ is the complete elliptic integral of the first kind.

3.12 Solve for the potential in Problem 3.1, using the appropriate Green function obtained in the text, and verify that the answer obtained in this way agrees with the direct solution from the differential equation.

3.13 A line charge of length $2d$ with a total charge Q has a linear charge density varying as $(d^2 - z^2)$, where z is the distance from the midpoint. A grounded, conducting, spherical shell of inner radius $b > d$ is centered at the midpoint of the line charge.

(a) Find the potential everywhere inside the spherical shell as an expansion in Legendre polynomials.

(b) Calculate the surface-charge density induced on the shell.

(c) Discuss your answers to (a) and (b) in the limit that $d \ll b$.

3.14 (a) Starting from the Bessel differential equation, verify Eq. (3.112) or equivalently that

$$\frac{1}{\rho} \delta(\rho - \rho') = \int_0^\infty k J_m(k\rho) J_m(k\rho') dk$$

(b) Obtain the following expansion:

$$\frac{1}{|\mathbf{x} - \mathbf{x}'|} = \sum_{m=-\infty}^{\infty} \int_0^\infty dk e^{im(\phi - \phi')} J_m(k\rho) J_m(k\rho') e^{-k(z_> - z_<)}$$

(c) By appropriate limiting procedures prove the following expansions:

$$\frac{1}{\sqrt{\rho^2 + z^2}} = \int_0^\infty e^{-k|z|} J_0(k\rho) dk$$

$$J_0(k\sqrt{\rho^2 + \rho'^2 - 2\rho\rho' \cos \phi}) = \sum_{m=-\infty}^{\infty} e^{im\phi} J_m(k\rho) J_m(k\rho')$$

$$e^{ik\rho \cos \phi} = \sum_{m=-\infty}^{\infty} i^m e^{im\phi} J_m(k\rho)$$

(d) From the last result obtain an integral representation of the Bessel function:

$$J_m(x) = \frac{1}{2\pi i^m} \int_0^{2\pi} e^{ix \cos \phi - im\phi} d\phi$$

Compare the standard integral representations.

3.15 The Dirichlet Green function for the unbounded space between the planes at $z = 0$ and $z = L$ allows discussion of a point charge or a distribution of charge between parallel conducting planes held at zero potential.

(a) Using cylindrical coordinates show that one form of the Green function is

$$G(\mathbf{x}, \mathbf{x}') = \frac{4}{L} \sum_{n=1}^{\infty} \sum_{m=-\infty}^{\infty} e^{im(\phi - \phi')} \sin\left(\frac{n\pi z}{L}\right) \sin\left(\frac{n\pi z'}{L}\right) I_m\left(\frac{n\pi}{L} \rho_<\right) K_m\left(\frac{n\pi}{L} \rho_>\right)$$

(b) Show that an alternative form of the Green function is

$$G(\mathbf{x}, \mathbf{x}') = 2 \sum_{m=-\infty}^{\infty} \int_0^{\infty} dk e^{im(\phi-\phi')} J_m(k\rho) J_m(k\rho') \frac{\sinh(kz_<) \sinh[k(L-z_>)]}{\sinh(kL)}$$

3.16 The configuration of Problem 3.11 is modified by placing a conducting plane held at zero potential parallel to and a distance L away from the plane with the disc insert in it. For definiteness put the grounded plane at $z=0$ and the other plane with the center of the disc on the z -axis at $z=L$.

(a) Show that the potential between the planes can be written in cylindrical coordinates (z, ρ, ϕ) as

$$\Phi(z, \rho) = V \int_0^{\infty} d\lambda J_1(\lambda) J_0(\lambda\rho/a) \frac{\sinh(\lambda z/a)}{\sinh(\lambda L/a)}$$

(b) Show that in the limit $a \rightarrow \infty$ with z, ρ, L fixed the solution of part (a) reduces to the expected result. Viewing your result as the lowest order answer in an expansion in powers of a^{-1} , consider the question of corrections to the lowest order expression if a is large compared to ρ and L , but not infinite. Are there difficulties? Can you obtain an explicit estimate of the corrections?

(c) Consider the limit of $L \rightarrow \infty$ with $(L-z)$, a and ρ fixed and show that the results of Problem 3.11 are recovered. What about corrections for $L \gg a$, but not $L \rightarrow \infty$?

3.17 Consider a point charge q between two infinite parallel conducting planes held at zero potential. Let the planes be located at $z=0$ and $z=L$ in a cylindrical coordinate system, with the charge on the z axis at $z=z_0$, $0 < z_0 < L$. Use Green's reciprocity theorem of Problem 1.12 with Problem 3.16 as the comparison problem.

(a) Show that the amount of induced charge on the plate at $z=L$ inside a circle of radius a whose center is on the z axis is given by

$$Q_L(a) = -\frac{q}{V} \Phi(z_0, 0)$$

where $\Phi(z_0, 0)$ is the potential of Problem 3.16 evaluated at $z=z_0$, $\rho=0$. Find the total charge induced on the upper plate. Compare with the solution (in method and answer) of Problem 1.13.

(b) Show that the induced charge density on the upper plate can be written as

$$\sigma(\rho) = -\frac{q}{2\pi} \int_0^{\infty} dk \frac{\sinh(kz_0)}{\sinh(kL)} k J_0(k\rho)$$

This integral can be expressed (see, for example, *Gradshteyn and Ryzhik*, p. 728, formula 6.666) as an infinite series involving the modified Bessel functions $K_0(n\pi\rho/L)$, showing that at large radial distances the induced charge density falls off as $(\rho)^{-1/2} e^{-\pi\rho/L}$.

3.18 (a) From the results of Problem 3.15 or from first principles show that the potential of a point charge q between two infinite parallel conducting planes held at zero potential can be written as

$$\Phi(z, \rho) = \frac{4q}{L} \sum_{n=1}^{\infty} \sin\left(\frac{n\pi z_0}{L}\right) \sin\left(\frac{n\pi z}{L}\right) K_0\left(\frac{n\pi\rho}{L}\right)$$

where the planes are at $z=0$ and $z=L$ and the charge is on the z axis at the point $z=z_0$.

(b) Calculate the induced surface charge densities $\sigma_0(\rho)$ and $\sigma_L(\rho)$ on the lower and upper plates. The result for $\sigma_L(\rho)$ is

$$\sigma_L(\rho) = \frac{q}{L^2} \sum_{n=1}^{\infty} (-1)^n n \sin\left(\frac{n\pi z_0}{L}\right) K_0\left(\frac{n\pi\rho}{L}\right)$$

Discuss the connection of this expression with that of Problem 3.17(b).

(c) From the answer in (b) calculate the total charge Q_L on the plate at $z=L$. By summing the Fourier series or by other means of comparison, check your answer against the known expression of Problem 1.13. [C. Y. Fong and C. Kittel, *Am. J. Phys.* **35**, 1091 (1967).]

3.19 (a) By using the Green function of Problem 3.15(b) in the limit $L \rightarrow \infty$, show that the capacitance of a flat, thin, circular, conducting disc of radius R located parallel to, and a distance d above, a grounded conducting plane is given by

$$C^{-1} = \int_0^{\infty} dk (1 - e^{-2kd}) \frac{\left[\int_0^R \rho J_0(k\rho) \sigma(\rho) d\rho \right]^2}{\left[\int_0^R \rho \sigma(\rho) d\rho \right]^2}$$

where $\sigma(\rho)$ is the charge density on the disc.

(b) Use the expression in part (a) as a variational or stationary principle for C^{-1} with the approximation that $\sigma(\rho)$ is constant. Show explicitly that you obtain the correct limiting value for C^{-1} as $d \ll R$. Determine an approximate value of C^{-1} for an isolated disc ($d \gg R$) and evaluate the ratio of it to the exact result, $C^{-1} = (\pi/2)R^{-1}$.

(c) As a better trial form for $\sigma(\rho)$ consider a linear combination of a constant and $(R^2 - \rho^2)^{-1/2}$, the latter being the correct form for an isolated disc.

For part (b) the following integrals may be of use:

$$\int_0^{\infty} dt [J_1(t)/t]^2 = \frac{4}{3\pi}, \quad \int_0^{\infty} dt J_1^2(t)/t = \frac{1}{2}$$

3.20 The geometry of a two-dimensional potential problem is defined in polar coordinates by the surfaces $\phi=0$, $\phi=\beta$, and $\rho=a$, as indicated in the sketch.

Problem 3.20

Using separation of variables in polar coordinates, show that the Green function can be written as

$$G(\rho, \phi; \rho', \phi') = \sum_{m=1}^{\infty} \frac{4}{m} \rho_{<}^{m\pi/\beta} \left(\frac{1}{\rho_{>}^{m\pi/\beta}} - \frac{\rho_{>}^{m\pi/\beta}}{a^{2m\pi/\beta}} \right) \sin \left(\frac{m\pi\phi}{\beta} \right) \sin \left(\frac{m\pi\phi'}{\beta} \right)$$

- 3.21 A unit point charge is located at the point (ρ', ϕ', z') inside a grounded cylindrical box defined by the surfaces $z=0$, $z=L$, $\rho=a$. Show that the potential inside the box can be expressed in the following alternative forms:

$$\begin{aligned} \Phi(\mathbf{x}, \mathbf{x}') &= \frac{4}{a} \sum_{m=-\infty}^{\infty} \sum_{n=1}^{\infty} \frac{e^{im(\phi-\phi')} J_m \left(\frac{x_{mn}\rho}{a} \right) J_m \left(\frac{x_{mn}\rho'}{a} \right)}{x_{mn} J_{m+1}^2(x_{mn}) \sinh \left(\frac{x_{mn}L}{a} \right)} \\ &\quad \times \sinh \left[\frac{x_{mn}}{a} z_{<} \right] \sinh \left[\frac{x_{mn}}{a} (L - z_{>}) \right] \\ \Phi(\mathbf{x}, \mathbf{x}') &= \frac{4}{L} \sum_{m=-\infty}^{\infty} \sum_{n=1}^{\infty} e^{im(\phi-\phi')} \sin \left(\frac{n\pi z}{L} \right) \sin \left(\frac{n\pi z'}{L} \right) \frac{I_m \left(\frac{n\pi\rho_{<}}{L} \right)}{I_m \left(\frac{n\pi a}{L} \right)} \\ &\quad \times \left[I_m \left(\frac{n\pi a}{L} \right) K_m \left(\frac{n\pi\rho_{>}}{L} \right) - K_m \left(\frac{n\pi a}{L} \right) I_m \left(\frac{n\pi\rho_{>}}{L} \right) \right] \\ \Phi(\mathbf{x}, \mathbf{x}') &= \frac{8}{La^2} \sum_{m=-\infty}^{\infty} \sum_{k=1}^{\infty} \sum_{n=1}^{\infty} \frac{e^{im(\phi-\phi')} \sin \left(\frac{k\pi z}{L} \right) \sin \left(\frac{k\pi z'}{L} \right) J_m \left(\frac{x_{mn}\rho}{a} \right) J_m \left(\frac{x_{mn}\rho'}{a} \right)}{\left[\left(\frac{x_{mn}}{a} \right)^2 + \left(\frac{k\pi}{L} \right)^2 \right] J_{m+1}^2(x_{mn})} \end{aligned}$$

Discuss the relation of the last expansion (with its extra summation) to the other two.

- 3.22 The walls of the conducting cylindrical box of Problem 3.21 are all at zero potential, except for a disc in the upper end, defined by $\rho=b < a$, at potential V .
 (a) Using the various forms of the Green function obtained in Problem 3.21, find three expansions for the potential inside the cylinder.
 (b) For each series, calculate numerically the ratio of the potential at $\rho=0$, $z=L/2$ to the potential of the disc, assuming $b=L/4=a/2$. Try to obtain at least two-significant-figure accuracy. Is one series less rapidly convergent than the others? Why?
 (Jahnke, Emde and Lösch have tables of J_0 and J_1 , I_0 and I_1 , $(2/\pi)K_0$ and $(2/\pi)K_1$. Watson also has numerous tables.)

- 3.23 Consider the surface charge densities for the problem of Section 3.13 of the conducting plane with a circular hole of radius a .
 (a) Show that the surface charge densities on the top and bottom of the plane for $\rho \geq a$ are

$$\sigma_+(\rho) = -\frac{E_0}{4\pi} + \Delta\sigma(\rho)$$

$$\sigma_-(\rho) = \frac{E_1}{4\pi} + \Delta\sigma(\rho)$$

where

$$\Delta\sigma(\rho) = -\frac{(E_0 - E_1)}{4\pi^2} \left[\frac{a}{\sqrt{\rho^2 - a^2}} - \sin^{-1} \left(\frac{a}{\rho} \right) \right]$$

How does $\Delta\sigma(\rho)$ behave for large ρ ? Is $\Delta\sigma(\rho)$, defined in terms of $\Phi^{(1)}$, zero for $\rho < a$? Explain.

(b) Show by direct integration that

$$\lim_{R \rightarrow \infty} \left[2\pi \int_a^R d\rho \rho (\sigma_+ + \sigma_-) + 2\pi \int_0^R d\rho \rho \left(\frac{E_0 - E_1}{4\pi} \right) \right] = 0$$

Interpret.

Multipoles, Electrostatics of Macroscopic Media, Dielectrics

This chapter is first concerned with the potential due to localized charge distributions and its expansion in multipoles. The development is made in terms of spherical harmonics, but contact is established with the rectangular components for the first few multipoles. The energy of a multipole in an external field is then discussed. An elementary derivation of the macroscopic equations of electrostatics is sketched, but a careful treatment is deferred to Chapter 6. Dielectrics and the appropriate boundary conditions are then described, and some typical boundary-value problems with dielectrics are solved. Simple classical models are used to illustrate the main features of atomic polarizability and susceptibility. Finally the question of electrostatic energy and forces in the presence of dielectrics is discussed.

4.1 Multipole Expansion

A localized distribution of charge is described by the charge density $\rho(\mathbf{x}')$, which is nonvanishing only inside a sphere of radius R^* around some origin. The potential outside the sphere can be written as an expansion in spherical harmonics:

$$\Phi(\mathbf{x}) = \sum_{l=0}^{\infty} \sum_{m=-l}^l \frac{4\pi}{2l+1} q_{lm} \frac{Y_{lm}(\theta, \phi)}{r^{l+1}} \quad (4.1)$$

where the particular choice of constant coefficients is made for later convenience. Equation (4.1) is called a multipole expansion; the $l=0$ term is called the monopole term, $l=1$ are the dipole terms, etc. The reason for these names

* The sphere of radius R is an arbitrary conceptual device employed merely to divide space into regions with and without charge. If the charge density falls off with distance faster than any power, the expansion in multipoles is valid at large enough distances.

becomes clear below. The problem to be solved is the determination of the constants q_{lm} in terms of the properties of the charge density $\rho(\mathbf{x}')$. The solution is very easily obtained from the integral (1.17) for the potential:

$$\Phi(\mathbf{x}) = \int \frac{\rho(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3x'$$

with expansion (3.70) for $1/|\mathbf{x} - \mathbf{x}'|$. Since we are interested at the moment in the potential outside the charge distribution, $r_< = r'$ and $r_> = r$. Then we find:

$$\Phi(\mathbf{x}) = 4\pi \sum_{l,m} \frac{1}{2l+1} \left[\int Y_{lm}^*(\theta', \phi') r'^l \rho(\mathbf{x}') d^3x' \right] \frac{Y_{lm}(\theta, \phi)}{r^{l+1}} \quad (4.2)$$

Consequently the coefficients in (4.1) are:

$$q_{lm} = \int Y_{lm}^*(\theta', \phi') r'^l \rho(\mathbf{x}') d^3x' \quad (4.3)$$

These coefficients are called *multipole moments*. To see the physical interpretation of them we exhibit the first few explicitly in terms of cartesian coordinates:

$$q_{00} = \frac{1}{\sqrt{4\pi}} \int \rho(\mathbf{x}') d^3x' = \frac{1}{\sqrt{4\pi}} q \quad (4.4)$$

$$\left. \begin{aligned} q_{11} &= -\sqrt{\frac{3}{8\pi}} \int (x' - iy') \rho(\mathbf{x}') d^3x' = -\sqrt{\frac{3}{8\pi}} (p_x - ip_y) \\ q_{10} &= \sqrt{\frac{3}{4\pi}} \int z' \rho(\mathbf{x}') d^3x' = \sqrt{\frac{3}{4\pi}} p_z \end{aligned} \right\} \quad (4.5)$$

$$\left. \begin{aligned} q_{22} &= \frac{1}{4} \sqrt{\frac{15}{2\pi}} \int (x' - iy')^2 \rho(\mathbf{x}') d^3x' = \frac{1}{12} \sqrt{\frac{15}{2\pi}} (Q_{11} - 2iQ_{12} - Q_{22}) \\ q_{21} &= -\sqrt{\frac{15}{8\pi}} \int z'(x' - iy') \rho(\mathbf{x}') d^3x' = -\frac{1}{3} \sqrt{\frac{15}{8\pi}} (Q_{13} - iQ_{23}) \\ q_{20} &= \frac{1}{2} \sqrt{\frac{5}{4\pi}} \int (3z'^2 - r'^2) \rho(\mathbf{x}') d^3x' = \frac{1}{2} \sqrt{\frac{5}{4\pi}} Q_{33} \end{aligned} \right\} \quad (4.6)$$

Only the moments with $m \geq 0$ have been given, since (3.54) shows that for a real charge density the moments with $m < 0$ are related through

$$q_{l,-m} = (-1)^m q_{lm}^* \quad (4.7)$$

In equations (4.4)–(4.6), q is the total charge, or monopole moment, \mathbf{p} is the electric dipole moment:

$$\mathbf{p} = \int \mathbf{x}' \rho(\mathbf{x}') d^3x' \quad (4.8)$$

and Q_{ij} is the traceless quadrupole moment tensor:

$$Q_{ij} = \int (3x'_i x'_j - r'^2 \delta_{ij}) \rho(\mathbf{x}') d^3 x' \quad (4.9)$$

We see that the l th multipole coefficients $[(2l+1)$ in number] are linear combinations of the corresponding multipoles expressed in rectangular coordinates. The expansion of $\Phi(\mathbf{x})$ in rectangular coordinates:

$$\Phi(\mathbf{x}) = \frac{q}{r} + \frac{\mathbf{p} \cdot \mathbf{x}}{r^3} + \frac{1}{2} \sum_{i,j} Q_{ij} \frac{x_i x_j}{r^5} + \dots \quad (4.10)$$

by direct Taylor series expansion of $1/|\mathbf{x}-\mathbf{x}'|$ will be left as an exercise for the reader. It becomes increasingly cumbersome to continue the expansion in (4.10) beyond the quadrupole terms.

The electric field components for a given multipole can be expressed most easily in terms of spherical coordinates. The negative gradient of a term in (4.1) with definite l, m has spherical components:

$$\left. \begin{aligned} E_r &= \frac{4\pi(l+1)}{2l+1} q_{lm} \frac{Y_{lm}(\theta, \phi)}{r^{l+2}} \\ E_\theta &= -\frac{4\pi}{2l+1} q_{lm} \frac{1}{r^{l+2}} \frac{\partial}{\partial \theta} Y_{lm}(\theta, \phi) \\ E_\phi &= -\frac{4\pi}{2l+1} q_{lm} \frac{1}{r^{l+2}} \frac{im}{\sin \theta} Y_{lm}(\theta, \phi) \end{aligned} \right\} \quad (4.11)$$

$\partial Y_{lm}/\partial \theta$ and $Y_{lm}/\sin \theta$ can be expressed as linear combinations of other Y_{lm} 's, but the expressions are not particularly illuminating and so will be omitted. The proper way to describe a vector multipole field is by *vector* spherical harmonics, discussed in Chapter 16.

For a dipole \mathbf{p} along the z axis, the fields in (4.11) reduce to the familiar form:

$$\left. \begin{aligned} E_r &= \frac{2p \cos \theta}{r^3} \\ E_\theta &= \frac{p \sin \theta}{r^3} \\ E_\phi &= 0 \end{aligned} \right\} \quad (4.12)$$

These dipole fields can be written in vector form by recombining (4.12) or by directly operating with the gradient on the dipole term in (4.10). The result for the field at a point \mathbf{x} due to a dipole \mathbf{p} at the point \mathbf{x}_0 is:

$$\mathbf{E}(\mathbf{x}) = \frac{3\mathbf{n}(\mathbf{p} \cdot \mathbf{n}) - \mathbf{p}}{|\mathbf{x} - \mathbf{x}_0|^3} \quad (4.13)$$

where \mathbf{n} is a unit vector directed from \mathbf{x}_0 to \mathbf{x} .

There are two important remarks to be made. The first concerns the relationship of the Cartesian multipole moments like (4.8) to the spherical multipole moments (4.3). The former are $(l+1)(l+2)/2$ in number and for $l > 1$ are more numerous than the $(2l+1)$ spherical components. There is no contradiction here. The root of the differences lies in the different rotational transformation properties of the two types of multipole moments—see Problem 4.3. Note that for $l=2$ we have recognized the difference by defining a *traceless* Cartesian quadrupole moment (4.9).

The second remark is that in general the multipole moment coefficients in the expansion (4.1) depend upon the choice of origin. As a blatant example, consider a *point charge* e located at $\mathbf{x}_0 = (r_0, \theta_0, \phi_0)$. It has a multipole expansion of the form (4.1) with multipole moments,

$$q_{lm} = e r_0^l Y_{lm}^*(\theta_0, \phi_0)$$

These are nonvanishing for all l, m in general. Only the $l=0$ multipole $q_{00} = e/\sqrt{4\pi}$ is independent of the location of the point charge. For two point charges $+e$ and $-e$ at \mathbf{x}_0 and \mathbf{x}_1 , respectively, the multipole moments are

$$q_{lm} = e[r_0^l Y_{lm}^*(\theta_0, \phi_0) - r_1^l Y_{lm}^*(\theta_1, \phi_1)]$$

Now the $l=0$ multipole moment of the system vanishes, and the $l=1$ moments are

$$q_{10} = \sqrt{\frac{3}{4\pi}} e(z_0 - z_1)$$

$$q_{11} = -\sqrt{\frac{3}{8\pi}} e[(x_0 - x_1) - i(y_0 - y_1)]$$

These moments are independent of the location of the origin, depending only on the relative position of the two charges, but all higher moments depend on the location of the origin as well. These simple examples are special cases of general theorem (see Problem 4.4). The values of q_{lm} for the *lowest nonvanishing multipole moment* of any charge distribution are *independent of the choice of origin* of the coordinates, but all higher multipole moments do in general depend on the location of the origin.

Before leaving the general formulation of multipoles, we consider a result that is useful in elucidating the basic difference between electric and magnetic dipoles (see Section 5.6) as well as in other contexts. Consider a localized charge distribution $\rho(\mathbf{x})$ that gives rise to an electric field $\mathbf{E}(\mathbf{x})$ throughout space. We wish to calculate the integral of \mathbf{E} over the volume of a sphere of radius R . We begin by examining the problem in general, but then specialize to the two extremes shown in Fig. 4.1, one in which the sphere contains all of the charge and the other in which the charge lies external to the sphere. Choosing the origin of coordinates at the center of the sphere, we have the volume integral of the

Fig. 4.1 Two configurations of charge density and the spheres within which the volume integral of electric field is to be calculated.

electric field,

$$\int_{r < R} \mathbf{E}(\mathbf{x}) d^3x = - \int_{r < R} \nabla \Phi d^3x \quad (4.14)$$

This can be converted to an integral over the surface of the sphere:

$$\int_{r < R} \mathbf{E}(\mathbf{x}) d^3x = - \int_{r=R} R^2 d\Omega \Phi(\mathbf{x}) \mathbf{n} \quad (4.15)$$

where \mathbf{n} is the outwardly directed normal ($\mathbf{n} = \mathbf{x}/R$). Substitution of (1.17) for the potential leads to

$$\int_{r < R} \mathbf{E}(\mathbf{x}) d^3x = -R^2 \int d^3x' \rho(\mathbf{x}') \int_{r=R} d\Omega \frac{\mathbf{n}}{|\mathbf{x} - \mathbf{x}'|} \quad (4.16)$$

To perform the angular integration we first observe that \mathbf{n} can be written in terms of the spherical angles (θ, ϕ) as

$$\mathbf{n} = \mathbf{i} \sin \theta \cos \phi + \mathbf{j} \sin \theta \sin \phi + \mathbf{k} \cos \theta$$

Evidently the different components of \mathbf{n} are linear combinations of Y_{lm} for $l=1$ only. When (3.38) or (3.70) is inserted into (4.16), orthogonality of the Y_{lm} will eliminate all but the $l=1$ term in the series. Thus we have

$$\int_{r=R} d\Omega \frac{\mathbf{n}}{|\mathbf{x} - \mathbf{x}'|} = \frac{r_{<}}{r_{>}^2} \int d\Omega \mathbf{n} \cos \gamma \quad (4.16')$$

where $\cos \gamma = \cos \theta \cos \theta' + \sin \theta \sin \theta' \cos(\phi - \phi')$. The angular integral is equal

to $4\pi\mathbf{n}'/3$, where $\mathbf{n}' = \mathbf{r}'/r'$. Thus the integral (4.16) is

$$\int_{r < R} \mathbf{E}(\mathbf{x}) d^3x = -\frac{4\pi R^2}{3} \int d^3x' \frac{r_{<}}{r_{>}^2} \mathbf{n}' \rho(\mathbf{x}') \quad (4.17)$$

where $(r_{<}, r_{>}) = (r', R)$ or (R, r') depending on which of r' and R is larger.

If the sphere of radius R completely encloses the charge density, as indicated in Fig. 4.1a, then $r_{<} = r'$ and $r_{>} = R$ in (4.17). The volume integral of the electric field over the sphere then becomes

$$\int_{r < R} \mathbf{E}(\mathbf{x}) d^3x = -\frac{4\pi}{3} \mathbf{p} \quad (4.18)$$

where \mathbf{p} is the electric dipole moment (4.8) of the charge distribution with respect to the center of the sphere. Note that this volume integral is independent of the size of the *spherical* region of integration provided all the charge is inside.

If, on the other hand, the situation is as depicted in Fig. 4.1b, with the charge all exterior to the sphere of interest, $r_{<} = R$ and $r_{>} = r'$ in (4.17). Then we have

$$\int_{r < R} \mathbf{E}(\mathbf{x}) d^3x = -\frac{4\pi R^3}{3} \int d^3x' \frac{\mathbf{n}'}{r'^2} \rho(\mathbf{x}')$$

From Coulomb's law (1.5) the integral can be recognized to be the negative of the electric field at the center of the sphere. Thus the volume integral of \mathbf{E} is

$$\int_{r < R} \mathbf{E}(\mathbf{x}) d^3x = \frac{4\pi}{3} R^3 \mathbf{E}(0) \quad (4.19)$$

In other words, the average value of the electric field over a spherical volume containing no charge is the value of the field at the center of the sphere.

The result (4.18) implies modification of (4.13) for the electric field of a dipole. In order to be consistent with (4.18) the dipole field must be written as

$$\mathbf{E}(\mathbf{x}) = \frac{3\mathbf{n}(\mathbf{p} \cdot \mathbf{n}) - \mathbf{p}}{|\mathbf{x} - \mathbf{x}_0|^3} - \frac{4\pi}{3} \mathbf{p} \delta(\mathbf{x} - \mathbf{x}_0) \quad (4.20)$$

The added delta function does not contribute to the field away from the site of the dipole. Its purpose is to yield the required volume integral (4.18), with the *convention* that the volume integral of the first term is zero (from angular integration), the singularity at $\mathbf{x} = \mathbf{x}_0$ causing an otherwise ambiguous result. Equation (4.20) and its magnetic dipole counterpart (5.64), when handled carefully, can be employed as if the dipoles were idealized point dipoles, the delta function terms carrying the essential information about the actually finite distributions of charge and current.

4.2 Multipole Expansion of the Energy of a Charge Distribution in an External Field

If a localized charge distribution described by $\rho(\mathbf{x})$ is placed in an *external* potential $\Phi(\mathbf{x})$, the electrostatic energy of the system is:

$$W = \int \rho(\mathbf{x}) \Phi(\mathbf{x}) d^3x \quad (4.21)$$

If the potential Φ is slowly varying over the region where $\rho(\mathbf{x})$ is nonnegligible, then it can be expanded in a Taylor series around a suitably chosen origin:

$$\Phi(\mathbf{x}) = \Phi(0) + \mathbf{x} \cdot \nabla \Phi(0) + \frac{1}{2} \sum_i \sum_j x_i x_j \frac{\partial^2 \Phi}{\partial x_i \partial x_j}(0) + \dots \quad (4.22)$$

Utilizing the definition of the electric field $\mathbf{E} = -\nabla \Phi$, the last two terms can be rewritten. Then (4.22) becomes:

$$\Phi(\mathbf{x}) = \Phi(0) - \mathbf{x} \cdot \mathbf{E}(0) - \frac{1}{2} \sum_i \sum_j x_i x_j \frac{\partial E_j}{\partial x_i}(0) + \dots$$

Since $\nabla \cdot \mathbf{E} = 0$ for the external field, we can subtract

$$\frac{1}{6} r^2 \nabla \cdot \mathbf{E}(0)$$

from the last term to obtain finally the expansion:

$$\Phi(\mathbf{x}) = \Phi(0) - \mathbf{x} \cdot \mathbf{E}(0) - \frac{1}{6} \sum_i \sum_j (3x_i x_j - r^2 \delta_{ij}) \frac{\partial E_j}{\partial x_i}(0) + \dots \quad (4.23)$$

When this is inserted into (4.21) and the definitions of total charge, dipole moment (4.8) and quadrupole moment (4.9), are employed, the energy takes the form:

$$W = q\Phi(0) - \mathbf{p} \cdot \mathbf{E}(0) - \frac{1}{6} \sum_i \sum_j Q_{ij} \frac{\partial E_j}{\partial x_i}(0) + \dots \quad (4.24)$$

This expansion shows the characteristic way in which the various multipoles interact with an external field—the charge with the potential, the dipole with the electric field, the quadrupole with the field gradient, and so on.

In nuclear physics the quadrupole interaction is of particular interest. Atomic nuclei can possess electric quadrupole moments, and their magnitudes and signs reflect the nature of the forces between neutrons and protons, as well as the shapes of the nuclei themselves. The energy levels or states of a nucleus are described by the quantum numbers of total angular momentum J and its projection M along the z axis, as well as others which we will denote by a general index α . A given nuclear state has associated with it a quantum-mechanical charge density* $\rho_{JM\alpha}(\mathbf{x})$, which depends on the quantum numbers (J, M, α), but

* See Blatt and Weisskopf, pp. 23 ff., for an elementary discussion of the quantum aspects of the problem.

which is cylindrically symmetric about the z axis. Thus the only nonvanishing quadrupole moment is q_{20} in (4.6), or Q_{33} in (4.9).^{*} The quadrupole moment of a nuclear state is defined as the value of $(1/e) Q_{33}$ with the charge density $\rho_{JM\alpha}(\mathbf{x})$, where e is the protonic charge:

$$Q_{JM\alpha} = \frac{1}{e} \int (3z^2 - r^2) \rho_{JM\alpha}(\mathbf{x}) d^3x \quad (4.25)$$

The dimensions of $Q_{JM\alpha}$ are consequently (length)². Unless the circumstances are exceptional (e.g., nuclei in atoms with completely closed electronic shells), nuclei are subjected to electric fields which possess field gradients in the neighborhood of the nuclei. Consequently, according to (4.24), the energy of the nuclei will have a contribution from the quadrupole interaction. The states of different M value for the same J will have different quadrupole moments $Q_{JM\alpha}$, and so a degeneracy in M value which may have existed will be removed by the quadrupole coupling to the "external" (crystal lattice, or molecular) electric field. Detection of these small energy differences by radiofrequency techniques allows the determination of the quadrupole moment of the nucleus.[†]

The interaction energy between two dipoles \mathbf{p}_1 and \mathbf{p}_2 can be obtained directly from (4.24) by using the dipole field (4.20). Thus, the mutual potential energy is

$$W_{12} = \frac{\mathbf{p}_1 \cdot \mathbf{p}_2 - 3(\mathbf{n} \cdot \mathbf{p}_1)(\mathbf{n} \cdot \mathbf{p}_2)}{|\mathbf{x}_1 - \mathbf{x}_2|^3} \quad (4.26)$$

where \mathbf{n} is a unit vector in the direction $(\mathbf{x}_1 - \mathbf{x}_2)$ and it is assumed that $\mathbf{x}_1 \neq \mathbf{x}_2$. The dipole-dipole interaction is attractive or repulsive, depending on the orientation of the dipoles. For fixed orientation and separation of the dipoles, the value of the interaction, averaged over the relative positions of the dipoles, is zero. If the moments are generally parallel, attraction (repulsion) occurs when the moments are oriented more or less parallel (perpendicular) to the line joining their centers. For antiparallel moments the reverse is true. The extreme values of the potential energy are equal in magnitude.

4.3 Elementary Treatment of Electrostatics with Ponderable Media

In Chapters 1, 2, and 3 we considered electrostatic potentials and fields in the presence of charges and conductors, but no other ponderable media. We therefore made no distinction between microscopic fields and macroscopic fields, although our treatment of conductors in an idealized fashion with *surface* charge densities implied a macroscopic description. Air is sufficiently tenuous that the

^{*} Actually Q_{11} and Q_{22} are different from zero, but are not independent of Q_{33} , being given by $Q_{11} = Q_{22} = -\frac{1}{2}Q_{33}$.

[†] "The quadrupole moment of a nucleus," denoted by Q , is defined as the value of $Q_{JM\alpha}$ in the state $M=J$. See Blatt and Weisskopf, *loc. cit.*

neglect of its dielectric properties causes no great error; our results so far are applicable there. But much of electrostatics concerns itself with charges and fields in ponderable media whose electric response must be taken into account. In the Introduction we indicated the need for averaging over macroscopically small, but microscopically large, regions in order to obtain the Maxwell equations appropriate for macroscopic phenomena. This is done in a careful fashion in Chapter 6, after the Maxwell equations with time variation have been discussed. For the present we merely remind the reader of the outlines of the elementary discussion of polarization in a fashion that glosses over difficult and sometimes subtle aspects of the averaging procedure and the introduction of the macroscopic quantities.

The first observation is that when an averaging is made of the homogeneous equation, $\nabla \times \mathbf{E}_{\text{micro}} = 0$, the same equation, namely,

$$\nabla \times \mathbf{E} = 0 \quad (4.27)$$

holds for the averaged, that is, the macroscopic, electric field \mathbf{E} . This means that the electric field is still derivable from a potential $\Phi(\mathbf{x})$ in electrostatics.

If an electric field is applied to a medium made up of a large number of atoms or molecules, the charges bound in each molecule will respond to the applied field and will execute perturbed motions. The molecular charge density will be distorted. The multipole moments of each molecule will be different from what they were in the absence of the field. In simple substances, when there is no applied field the multipole moments are all zero, at least when averaged over many molecules. The dominant molecular multipole with the applied field is the dipole. There is thus produced in the medium an *electric polarization* \mathbf{P} (dipole moment per unit volume) given by

$$\mathbf{P}(\mathbf{x}) = \sum_i N_i \langle \mathbf{p}_i \rangle \quad (4.28)$$

where \mathbf{p}_i is the dipole moment of the i th type of molecule in the medium, the average is taken over a small volume centered at \mathbf{x} and N_i is the average number per unit volume of the i th type of molecule at the point \mathbf{x} . If the molecules have a net charge e_i and, in addition, there is macroscopic excess or free charge, the charge density at the macroscopic level will be

$$\rho(\mathbf{x}) = \sum_i N_i \langle e_i \rangle + \rho_{\text{excess}} \quad (4.29)$$

Usually the average molecular charge is zero. Then the charge density is the excess or free charge (suitably averaged).

If we now look at the medium from a macroscopic point of view, we can build up the potential or field by linear superposition of the contributions from each macroscopically small volume element ΔV at the variable point \mathbf{x}' . Thus the charge of ΔV is $\rho(\mathbf{x}') \Delta V$ and the dipole moment of ΔV is $\mathbf{P}(\mathbf{x}') \Delta V$. If there are no higher macroscopic multipole moment densities, the potential $\Delta\Phi(\mathbf{x}, \mathbf{x}')$

caused by the configuration of moments in ΔV can be seen from (4.10) to be given without approximation by

$$\Delta\Phi(\mathbf{x}, \mathbf{x}') = \frac{\rho(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} \Delta V + \frac{\mathbf{P}(\mathbf{x}') \cdot (\mathbf{x} - \mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|^3} \Delta V \quad (4.30)$$

provided \mathbf{x} is outside ΔV . We now treat ΔV as (macroscopically) infinitesimal, put it equal to d^3x' , and integrate over all space to obtain the potential

$$\Phi(\mathbf{x}) = \int d^3x' \left[\frac{\rho(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} + \mathbf{P}(\mathbf{x}') \cdot \nabla' \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) \right] \quad (4.31)$$

The second term is analogous to the dipole layer potential (1.25), but is for a volume distribution of dipoles. An integration by parts transforms the potential into

$$\Phi(\mathbf{x}) = \int d^3x' \frac{1}{|\mathbf{x} - \mathbf{x}'|} [\rho(\mathbf{x}') - \nabla' \cdot \mathbf{P}(\mathbf{x}')] \quad (4.32)$$

This is just the customary expression for the potential caused by a charge distribution $(\rho - \nabla \cdot \mathbf{P})$. With $\mathbf{E} = -\nabla\Phi$, the first Maxwell equation therefore reads

$$\nabla \cdot \mathbf{E} = 4\pi[\rho - \nabla \cdot \mathbf{P}] \quad (4.33)$$

The presence of the divergence of \mathbf{P} in the effective charge density can be understood qualitatively. If the polarization is nonuniform there can be a net increase or decrease of charge within any small volume, as indicated schematically in Fig. 4.2.

With the definition of the *electric displacement* \mathbf{D} ,

$$\mathbf{D} = \mathbf{E} + 4\pi\mathbf{P} \quad (4.34)$$

(4.33) becomes the familiar

$$\nabla \cdot \mathbf{D} = 4\pi\rho \quad (4.35)$$

Equations (4.27) and (4.35) are the macroscopic counterparts of (1.13) and (1.14) of Chapter 1.

Fig. 4.2 Origin of polarization-charge density. Because of spatial variation of polarization more molecular charge may leave a given small volume than enters it. Only molecules near the boundary are shown.

As discussed in the Introduction, a *constitutive relation* connecting \mathbf{D} and \mathbf{E} is necessary before a solution for the electrostatic potential or fields can be obtained. In the subsequent sections of this chapter we assume that the response of the system to an applied field is linear. This excludes ferroelectricity from discussion, but otherwise is no real restriction provided the field strengths do not become extremely large. As a further simplification we suppose that the *medium is isotropic*. Then the induced polarization \mathbf{P} is parallel to \mathbf{E} with a coefficient of proportionality that is independent of direction:

$$\mathbf{P} = \chi_e \mathbf{E} \quad (4.36)$$

The constant χ_e is called the *electric susceptibility* of the medium. The displacement \mathbf{D} is therefore proportional to \mathbf{E} ,

$$\mathbf{D} = \epsilon \mathbf{E} \quad (4.37)$$

where

$$\epsilon = 1 + 4\pi\chi_e \quad (4.38)$$

is called the *dielectric constant* or relative electric permittivity.

If the dielectric is not only isotropic, but also uniform, then ϵ is independent of position. The divergence equations (4.35) can then be written

$$\nabla \cdot \mathbf{E} = 4\pi \left(\frac{\rho}{\epsilon} \right) \quad (4.39)$$

All problems *in that medium* are reduced to those of previous chapters, except that the electric fields produced by given charges are reduced by a factor $1/\epsilon$. The reduction can be understood in terms of a polarization of the atoms that produce fields in opposition to that of the given charge. One immediate consequence is that the capacitance of a capacitor is increased by a factor of ϵ if the empty space between the electrodes is filled with a dielectric with dielectric constant ϵ (true only to the extent that fringing fields can be neglected).

If the uniform medium does not fill all of the space where there are electric fields or, more generally, if there are different media juxtaposed, not necessarily linear in their responses, we must consider the question of boundary conditions on \mathbf{D} and \mathbf{E} at the interfaces between media. These boundary conditions are derived from the full set of Maxwell equations in Section I.5. The results are that the normal components of \mathbf{D} and the tangential components of \mathbf{E} on either side of an interface satisfy the *boundary conditions*, valid for time-varying as well as static fields,

$$\left. \begin{aligned} (\mathbf{D}_2 - \mathbf{D}_1) \cdot \mathbf{n}_{21} &= 4\pi\sigma \\ (\mathbf{E}_2 - \mathbf{E}_1) \times \mathbf{n}_{21} &= 0 \end{aligned} \right\} \quad (4.40)$$

where \mathbf{n}_{21} is a unit normal to the surface, directed from region 1 to region 2, and σ is the macroscopic surface charge density on the boundary surface (*not* including the polarization charge).

4.4 Boundary-Value Problems with Dielectrics

The methods of previous chapters for the solution of electrostatic boundary-value problems can readily be extended to handle the presence of dielectrics. In this section we treat a few examples of the various techniques applied to dielectric media.

To illustrate the method of images for dielectrics we consider a point charge q embedded in a semi-infinite dielectric ϵ_1 a distance d away from a plane interface which separates the first medium from another semi-infinite dielectric ϵ_2 . The surface may be taken as the plane $z=0$, as shown in Fig. 4.3. We must find the appropriate solution to the equations:

$$\left. \begin{aligned} \epsilon_1 \nabla \cdot \mathbf{E} &= 4\pi\rho, & z > 0 \\ \epsilon_2 \nabla \cdot \mathbf{E} &= 0, & z < 0 \\ \nabla \times \mathbf{E} &= 0, & \text{everywhere} \end{aligned} \right\} \quad (4.41)$$

and

subject to the boundary conditions at $z=0$:

$$\lim_{z \rightarrow 0^+} \begin{Bmatrix} \epsilon_1 E_z \\ E_x \\ E_y \end{Bmatrix} = \lim_{z \rightarrow 0^-} \begin{Bmatrix} \epsilon_2 E_z \\ E_x \\ E_y \end{Bmatrix} \quad (4.42)$$

Since $\nabla \times \mathbf{E} = 0$ everywhere, \mathbf{E} is derivable in the usual way from a potential Φ . In attempting to use the image method it is natural to locate an image charge q' at the symmetrical position A' shown in Fig. 4.4. Then for $z > 0$ the potential at a point P described by cylindrical coordinates (ρ, ϕ, z) will be

$$\Phi = \frac{1}{\epsilon_1} \left(\frac{q}{R_1} + \frac{q'}{R_2} \right), \quad z > 0 \quad (4.43)$$

where $R_1 = \sqrt{\rho^2 + (d-z)^2}$, $R_2 = \sqrt{\rho^2 + (d+z)^2}$. So far the procedure is completely analogous to the problem with a conducting material in place of the dielectric ϵ_2 for $z < 0$. But we now must specify the potential for $z < 0$. Since there are no charges in the region $z < 0$, it must be a solution of the Laplace equation without singularities in that region. Clearly the simplest assumption is that for $z < 0$ the

Fig. 4.3

Fig. 4.4

potential is equivalent to that of a charge q'' at the position A of the actual charge q :

$$\Phi = \frac{1}{\epsilon_2} \frac{q''}{R_1}, \quad z < 0 \quad (4.44)$$

Since

$$\left. \frac{\partial}{\partial z} \left(\frac{1}{R_1} \right) \right|_{z=0} = - \left. \frac{\partial}{\partial z} \left(\frac{1}{R_2} \right) \right|_{z=0} = \frac{d}{(\rho^2 + d^2)^{3/2}}$$

while

$$\left. \frac{\partial}{\partial \rho} \left(\frac{1}{R_1} \right) \right|_{z=0} = \left. \frac{\partial}{\partial \rho} \left(\frac{1}{R_2} \right) \right|_{z=0} = \frac{-\rho}{(\rho^2 + d^2)^{3/2}}$$

the boundary conditions (4.42) lead to the requirements:

$$\begin{aligned} q - q' &= q'' \\ \frac{1}{\epsilon_1} (q + q') &= \frac{1}{\epsilon_2} q'' \end{aligned}$$

These can be solved to yield the image charges q' and q'' :

$$\left. \begin{aligned} q' &= - \left(\frac{\epsilon_2 - \epsilon_1}{\epsilon_2 + \epsilon_1} \right) q \\ q'' &= \left(\frac{2\epsilon_2}{\epsilon_2 + \epsilon_1} \right) q \end{aligned} \right\} \quad (4.45)$$

For the two cases $\epsilon_2 > \epsilon_1$ and $\epsilon_2 < \epsilon_1$ the lines of force (actually lines of \mathbf{D}) are shown qualitatively in Fig. 4.5.

The polarization-charge density is given by $-\nabla \cdot \mathbf{P}$. Inside either dielectric, $\mathbf{P} = \chi_e \mathbf{E}$, so that $-\nabla \cdot \mathbf{P} = -\chi_e \nabla \cdot \mathbf{E} = 0$, except at the point charge q . At the surface, however, χ_e takes a discontinuous jump, $\Delta \chi_e = (1/4\pi)(\epsilon_1 - \epsilon_2)$ as z passes through $z=0$. This implies that there is a polarization surface-charge density on the plane $z=0$:

$$\sigma_{\text{pol}} = -(\mathbf{P}_2 - \mathbf{P}_1) \cdot \mathbf{n}_{21} \quad (4.46)$$

where \mathbf{n}_{21} is the unit normal from dielectric 1 to dielectric 2, and \mathbf{P}_i is the

Fig. 4.5 Lines of electric displacement for a point charge embedded in a dielectric ϵ_1 near a semi-infinite slab of dielectric ϵ_2 .

polarization in the dielectric i at $z=0$. Since

$$\mathbf{P}_i = \left(\frac{\epsilon_i - 1}{4\pi} \right) \mathbf{E} = - \left(\frac{\epsilon_i - 1}{4\pi} \right) \nabla \Phi$$

it is a simple matter to show that the polarization-charge density is

$$\sigma_{\text{pol}} = - \frac{q}{2\pi} \frac{(\epsilon_2 - \epsilon_1)}{\epsilon_1(\epsilon_2 + \epsilon_1)} \frac{d}{(\rho^2 + d^2)^{3/2}} \quad (4.47)$$

In the limit $\epsilon_2 \gg \epsilon_1$ the dielectric ϵ_2 behaves much like a conductor in that the electric field inside it becomes very small and the surface-charge density (4.47) approaches the value appropriate to a conducting surface.

The second illustration of electrostatic problems involving dielectrics is that of a dielectric sphere of radius a with dielectric constant ϵ placed in an initially uniform electric field which at large distances from the sphere is directed along the z axis and has magnitude E_0 , as indicated in Fig. 4.6. Both inside and outside the sphere there are no free charges. Consequently the problem is one of solving

Fig. 4.6

the Laplace equation with the proper boundary conditions at $r=a$. From the axial symmetry of the geometry we can take the solution to be of the form:

$$\text{INSIDE:} \quad \Phi_{\text{in}} = \sum_{l=0}^{\infty} A_l r^l P_l(\cos \theta) \quad (4.48)$$

$$\text{OUTSIDE:} \quad \Phi_{\text{out}} = \sum_{l=0}^{\infty} [B_l r^l + C_l r^{-(l+1)}] P_l(\cos \theta) \quad (4.49)$$

From the boundary condition at infinity ($\Phi \rightarrow -E_0 z = -E_0 r \cos \theta$) we find that the only nonvanishing B_l is $B_1 = -E_0$. The other coefficients are determined from the boundary conditions at $r=a$:

$$\left. \begin{array}{l} \text{TANGENTIAL } E: \quad -\frac{1}{a} \frac{\partial \Phi_{\text{in}}}{\partial \theta} \Big|_{r=a} = -\frac{1}{a} \frac{\partial \Phi_{\text{out}}}{\partial \theta} \Big|_{r=a} \\ \text{NORMAL } D: \quad -\epsilon \frac{\partial \Phi_{\text{in}}}{\partial r} \Big|_{r=a} = -\frac{\partial \Phi_{\text{out}}}{\partial r} \Big|_{r=a} \end{array} \right\} \quad (4.50)$$

When the series (4.48) and (4.49) are substituted, there result two series of Legendre polynomials equal to zero. Since these must vanish for all θ , the coefficient of each Legendre polynomial must vanish separately. For the first boundary condition this leads to the relations:

$$\left. \begin{array}{l} A_1 = -E_0 + \frac{C_1}{a^3} \\ A_l = \frac{C_l}{a^{2l+1}}, \quad \text{for } l \neq 1 \end{array} \right\} \quad (4.51)$$

while the second gives:

$$\left. \begin{array}{l} \epsilon A_1 = -E_0 - 2 \frac{C_1}{a^3} \\ \epsilon l A_l = -(l+1) \frac{C_l}{a^{2l+1}}, \quad \text{for } l \neq 1 \end{array} \right\} \quad (4.52)$$

The second equations in (4.51) and (4.52) can be satisfied simultaneously only with $A_l = C_l = 0$ for all $l \neq 1$. The remaining coefficients are given in terms of the applied electric field E_0 :

$$\left. \begin{array}{l} A_1 = -\left(\frac{3}{2+\epsilon}\right) E_0 \\ C_1 = \left(\frac{\epsilon-1}{\epsilon+2}\right) a^3 E_0 \end{array} \right\} \quad (4.53)$$

The potential is therefore

$$\left. \begin{array}{l} \Phi_{\text{in}} = -\left(\frac{3}{\epsilon+2}\right) E_0 r \cos \theta \\ \Phi_{\text{out}} = -E_0 r \cos \theta + \left(\frac{\epsilon-1}{\epsilon+2}\right) E_0 \frac{a^3}{r^2} \cos \theta \end{array} \right\} \quad (4.54)$$

Fig. 4.7 Dielectric sphere in a uniform field E_0 , showing the polarization on the left and the polarization charge with its associated, opposing, electric field on the right.

The potential inside the sphere describes a constant electric field parallel to the applied field with magnitude

$$E_{\text{in}} = \frac{3}{\epsilon + 2} E_0 < E_0 \text{ if } \epsilon > 1 \quad (4.55)$$

Outside the sphere the potential is equivalent to the applied field E_0 plus the field of an electric dipole at the origin with dipole moment:

$$p = \left(\frac{\epsilon - 1}{\epsilon + 2} \right) a^3 E_0 \quad (4.56)$$

oriented in the direction of the applied field. The dipole moment can be interpreted as the volume integral of the polarization \mathbf{P} . The polarization is

$$\mathbf{P} = \left(\frac{\epsilon - 1}{4\pi} \right) \mathbf{E} = \frac{3}{4\pi} \left(\frac{\epsilon - 1}{\epsilon + 2} \right) \mathbf{E}_0 \quad (4.57)$$

It is constant throughout the volume of the sphere and has a volume integral given by (4.56). The polarization surface-charge density is, according to (4.46), $\sigma_{\text{pol}} = (\mathbf{P} \cdot \mathbf{r})/r$:

$$\sigma_{\text{pol}} = \frac{3}{4\pi} \left(\frac{\epsilon - 1}{\epsilon + 2} \right) E_0 \cos \theta \quad (4.58)$$

This can be thought of as producing an internal field directed oppositely to the applied field, so reducing the field inside the sphere to its value (4.55), as sketched in Fig. 4.7.

The problem of a spherical cavity of radius a in a dielectric medium with dielectric constant ϵ and with an applied electric field E_0 parallel to the z axis, as shown in Fig. 4.8, can be handled in exactly the same way as the dielectric

Fig. 4.8 Spherical cavity in a dielectric with a uniform field applied.

sphere. In fact, inspection of boundary conditions (4.50) shows that the results for the cavity can be obtained from those of the sphere by the replacement $\epsilon \rightarrow (1/\epsilon)$. Thus, for example, the field inside the cavity is uniform, parallel to \mathbf{E}_0 , and of magnitude:

$$E_{\text{in}} = \frac{3\epsilon}{2\epsilon + 1} E_0 > E_0 \text{ if } \epsilon > 1 \quad (4.59)$$

Similarly, the field outside is the applied field plus that of a dipole at the origin *oriented oppositely* to the applied field and with dipole moment:

$$p = \left(\frac{\epsilon - 1}{2\epsilon + 1} \right) a^3 E_0 \quad (4.60)$$

4.5 Molecular Polarizability and Electric Susceptibility

In this section and the next we consider the relation between molecular properties and the macroscopically defined parameter, the electric susceptibility χ_e . Our discussion is in terms of simple classical models of the molecular properties, although a proper treatment necessarily would involve quantum-mechanical considerations. Fortunately, the simpler properties of dielectrics are amenable to classical analysis.

Before examining how the detailed properties of the molecules are related to the susceptibility we must make a distinction between the fields acting on the molecules in the medium and the applied field. The susceptibility is defined through the relation $\mathbf{P} = \chi_e \mathbf{E}$, where \mathbf{E} is the macroscopic electric field. In rarefied media where molecular separations are large there is little difference between the macroscopic field and that acting on any molecule or group of molecules. But in dense media with closely packed molecules the polarization of neighboring molecules gives rise to an internal field \mathbf{E}_i at any given molecule in addition to the average macroscopic field \mathbf{E} , so that the total field at the molecule is $\mathbf{E} + \mathbf{E}_i$. The internal field \mathbf{E}_i can be written as the difference of two terms,

$$\mathbf{E}_i = \mathbf{E}_{\text{near}} - \mathbf{E}_P \quad (4.61)$$

where \mathbf{E}_{near} is the actual contribution of the molecules close to the given molecule and \mathbf{E}_P is the contribution from those molecules treated in an average continuum approximation described by the polarization \mathbf{P} . What we are doing here is saying that close to the molecule in question we must take care to recognize the specific atomic configuration and locations of the nearby molecules. Inside some macroscopically small, but microscopically large, volume V we therefore subtract out the smoothed macroscopic equivalent of the nearby molecular contributions (\mathbf{E}_P) and replace it with the correctly evaluated contribution (\mathbf{E}_{near}). This difference is the extra internal field \mathbf{E}_i .

The result (4.18) for the integral of the electric field inside a spherical volume

of radius R containing a charge distribution can be used to calculate \mathbf{E}_P . If the volume V is chosen to be a sphere of radius R containing many molecules, the total dipole moment inside is

$$\mathbf{P} = \frac{4\pi R^3}{3} \mathbf{P}$$

provided V is small enough that \mathbf{P} is essentially constant throughout the volume. Then (4.18) shows that the average electric field inside the sphere (just what is desired for \mathbf{E}_P) is

$$\mathbf{E}_P = \frac{3}{4\pi R^3} \int_{r < R} \mathbf{E} d^3x = -\frac{4\pi}{3} \mathbf{P} \quad (4.62)$$

The internal field can therefore be written

$$\mathbf{E}_i = \frac{4\pi}{3} \mathbf{P} + \mathbf{E}_{\text{near}} \quad (4.63)$$

The field due to the molecules near by is more difficult to determine. *Lorentz* (p. 138) showed that for atoms in a simple cubic lattice \mathbf{E}_{near} vanishes at any lattice site. The argument depends on the symmetry of the problem, as can be seen as follows. Suppose that inside the sphere we have a cubic array of dipoles such as are shown in Fig. 4.9, with all their moments constant in magnitude and oriented along the same direction (remember that the sphere is macroscopically small even though it contains very many molecules). The positions of the dipoles are given by the coordinates \mathbf{x}_{ijk} with the components along the coordinate axes (ia, ja, ka), where a is the lattice spacing, and i, j, k each take on positive and negative integer values. The field at the origin due to all the dipoles is, according to (4.13),

$$\mathbf{E} = \sum_{i,j,k} \frac{3(\mathbf{p} \cdot \mathbf{x}_{ijk})\mathbf{x}_{ijk} - x_{ijk}^2 \mathbf{p}}{x_{ijk}^5} \quad (4.64)$$

Fig. 4.9 Calculation of the internal field—contribution from nearby molecules in a simple cubic lattice.

The x component of the field can be written in the form:

$$E_1 = \sum_{ijk} \frac{3(i^2 p_1 + i j p_2 + i k p_3) - (i^2 + j^2 + k^2) p_1}{a^3 (i^2 + j^2 + k^2)^{5/2}} \quad (4.65)$$

Since the indices run equally over positive and negative values, the cross terms involving $(i j p_2 + i k p_3)$ vanish. By symmetry the sums:

$$\sum_{ijk} \frac{i^2}{(i^2 + j^2 + k^2)^{5/2}} = \sum_{ijk} \frac{j^2}{(i^2 + j^2 + k^2)^{5/2}} = \sum_{ijk} \frac{k^2}{(i^2 + j^2 + k^2)^{5/2}}$$

are all equal. Consequently

$$E_1 = \sum_{ijk} \frac{[3i^2 - (i^2 + j^2 + k^2)] p_1}{a^3 (i^2 + j^2 + k^2)^{5/2}} = 0 \quad (4.66)$$

Similar arguments show that the y and z components vanish also. Hence $\mathbf{E}_{\text{near}} = 0$ for a simple cubic lattice.

If $\mathbf{E}_{\text{near}} = 0$ for a highly symmetric situation, it seems plausible that $\mathbf{E}_{\text{near}} = 0$ also for completely random situations. Hence we expect amorphous substances to have no internal field due to nearby molecules. For lattices other than simple cubic, the components of \mathbf{E}_{near} are related to the components of \mathbf{P} through a traceless tensor $s_{\alpha\beta}$ that has the symmetry properties of the lattice. Nevertheless, it is a good working assumption that $\mathbf{E}_{\text{near}} \approx 0$ for most materials.

The polarization vector \mathbf{P} was defined in (4.28) as

$$\mathbf{P} = N \langle \mathbf{p}_{\text{mol}} \rangle$$

where $\langle \mathbf{p}_{\text{mol}} \rangle$ is the average dipole moment of the molecules. This dipole moment is approximately proportional to the electric field acting on the molecule. To exhibit this dependence on electric field we define the *molecular polarizability* γ_{mol} as the ratio of the average molecular dipole moment to the applied field at the molecule. Taking account of the internal field (4.63), this gives:

$$\langle \mathbf{p}_{\text{mol}} \rangle = \gamma_{\text{mol}} (\mathbf{E} + \mathbf{E}_i) \quad (4.67)$$

γ_{mol} is, in principle, a function of the electric field, but for a wide range of field strengths is a constant which characterizes the response of the molecules to an applied field. Equation (4.67) can be combined with (4.28) and (4.63) to yield:

$$\mathbf{P} = N \gamma_{\text{mol}} \left(\mathbf{E} + \frac{4\pi}{3} \mathbf{P} \right) \quad (4.68)$$

where we have assumed $\mathbf{E}_{\text{near}} = 0$. Solving for \mathbf{P} in terms of \mathbf{E} and using the fact that $\mathbf{P} = \chi_e \mathbf{E}$ defines the electric susceptibility of a substance, we find

$$\chi_e = \frac{N \gamma_{\text{mol}}}{1 - \frac{4\pi}{3} N \gamma_{\text{mol}}} \quad (4.69)$$

as the relation between susceptibility (the macroscopic parameter) and molecular polarizability (the microscopic parameter). Since the dielectric constant is $\epsilon = 1 + 4\pi\chi_e$, it can be expressed in terms of γ_{mol} , or alternatively the molecular polarizability can be expressed in terms of the dielectric constant:

$$\gamma_{\text{mol}} = \frac{3}{4\pi N} \left(\frac{\epsilon - 1}{\epsilon + 2} \right) \quad (4.70)$$

This is called the *Clausius-Mossotti equation*, since Mossotti (in 1850) and Clausius independently (in 1879) established that for any given substance $(\epsilon - 1)/(\epsilon + 2)$ should be proportional to the density of the substance.* The relation holds best for dilute substances such as gases. For liquids and solids, (4.70) is only approximately valid, especially if the dielectric constant is large. The interested reader can refer to the books by Böttcher, Debye, and Fröhlich for further details.

4.6 Models for the Molecular Polarizability

The polarization of a collection of atoms or molecules can arise in two ways:

- (a) the applied field distorts the charge distributions and so produces an induced dipole moment in each molecule;
- (b) the applied field tends to line up the initially randomly oriented permanent dipole moments of the molecules.

To estimate the induced moments we consider a simple model of harmonically bound charges (electrons and ions). Each charge e is bound under the action of a restoring force

$$\mathbf{F} = -m\omega_0^2 \mathbf{x} \quad (4.71)$$

where m is the mass of the charge, and ω_0 the frequency of oscillation about equilibrium. Under the action of an electric field \mathbf{E} the charge is displaced from its equilibrium by an amount \mathbf{x} given by

$$m\omega_0^2 \mathbf{x} = e\mathbf{E}$$

Consequently the induced dipole moment is

$$\mathbf{p}_{\text{mol}} = e\mathbf{x} = \frac{e^2}{m\omega_0^2} \mathbf{E} \quad (4.72)$$

This means that the polarizability is $\gamma = e^2/m\omega_0^2$. If there are a set of charges e_i with masses m_i and oscillation frequencies ω_i in each molecule then the

* At optical frequencies, $\epsilon = n^2$, where n is the index of refraction. With n^2 replacing ϵ in (4.70), the equation is sometimes called the *Lorentz-Lorenz equation* (1880).

molecular polarizability is

$$\gamma_{\text{mol}} = \sum_i \frac{e_i^2}{m_i \omega_i^2} \quad (4.73)$$

To get a feeling for the order of magnitude of γ we can make two different estimates. Since γ has the dimensions of a volume, its magnitude must be of the order of molecular dimensions or less, namely $\gamma_{\text{el}} \leq 10^{-23} \text{ cm}^3$. Alternatively, we note that the binding frequencies of electrons in atoms must be of the order of light frequencies. Taking a typical wavelength of light as 3000 angstroms, we find $\omega \approx 6 \times 10^{15} \text{ sec}^{-1}$. Then the electronic contribution to γ is $\gamma_{\text{el}} \sim (e^2/m\omega^2) \sim 6 \times 10^{-24} \text{ cm}^3$, consistent with the molecular volume estimate. For gases at NTP the number of molecules per cubic centimeter is $N = 2.7 \times 10^{19}$, so that their susceptibilities should be of the order of $\chi_e \leq 10^{-4}$. This means dielectric constants differing from unity by a few parts in 10^3 , or less. Experimentally, typical values of dielectric constant are 1.00054 for air, 1.0072 for ammonia vapor, 1.0057 for methyl alcohol, 1.000068 for helium. For solid or liquid dielectrics, $N \sim 10^{22} - 10^{23} \text{ molecules/cm}^3$. Consequently, the susceptibility can be of the order of unity (to within a factor $10^{\pm 1}$) as is observed.*

The possibility that thermal agitation of the molecules could modify the result (4.73) for the induced dipole polarizability needs consideration. In statistical mechanics the probability distribution of particles in phase space (\mathbf{p} , \mathbf{q} space) is some function $f(H)$ of the Hamiltonian. For classical systems,

$$f(H) = e^{-H/kT} \quad (4.74)$$

is the Boltzmann factor. For the simple problem of the harmonically bound charge with an applied field in the z direction, the Hamiltonian is

$$H = \frac{1}{2m} \mathbf{p}^2 + \frac{m}{2} \omega_0^2 \mathbf{x}^2 - eEz \quad (4.75)$$

where here \mathbf{p} is the momentum of the charged particle. The average value of the dipole moment in the z direction is

$$\langle p_{\text{mol}} \rangle = \frac{\int d^3p \int d^3x (ez) f(H)}{\int d^3p \int d^3x f(H)} \quad (4.76)$$

If we introduce a displaced coordinate $\mathbf{x}' = \mathbf{x} - eE\mathbf{k}/m\omega_0^2$ then

$$H = \frac{1}{2m} \mathbf{p}^2 + \frac{m\omega_0^2}{2} (\mathbf{x}')^2 - \frac{e^2 E^2}{2m\omega_0^2} \quad (4.77)$$

* See *Handbook of Chemistry and Physics*, Chemical Rubber Publishing Co., or *American Institute of Physics Handbook*, ed. D. E. Gray, 3rd edition, McGraw-Hill, New York, (1972), for tables of dielectric constants of various substances.

and

$$\langle p_{\text{mol}} \rangle = \frac{\int d^3p \int d^3x' \left(ez' + \frac{e^2 E}{m\omega_0^2} \right) f(H)}{\int d^3p \int d^3x' f(H)} \quad (4.78)$$

Since H is even in z' the first integral vanishes. Thus, independent of the form of $f(H)$, we obtain

$$\langle p_{\text{mol}} \rangle = \frac{e^2}{m\omega_0^2} E$$

just as was found in (4.72), ignoring thermal motion.

The second type of polarizability is that caused by the partial orientation of otherwise random permanent dipole moments. This orientation polarization is important in “polar” substances such as HCl and H₂O and was first discussed by Debye (1912). All molecules are assumed to possess a permanent dipole moment \mathbf{p}_0 which can be oriented in any direction in space. In the absence of a field thermal agitation keeps the molecules randomly oriented so that there is no net dipole moment. With an applied field there is a tendency to line up along the field in the configuration of lowest energy. Consequently there will be an average dipole moment. To calculate this we note that the Hamiltonian of the molecule is given by

$$H = H_0 - \mathbf{p}_0 \cdot \mathbf{E} \quad (4.79)$$

where H_0 is a function of only the “internal” coordinates of the molecule. Using the Boltzmann factor (4.74), we can write the average dipole moment as:

$$\langle p_{\text{mol}} \rangle = \frac{\int d\Omega p_0 \cos \theta \exp \left(\frac{p_0 E \cos \theta}{kT} \right)}{\int d\Omega \exp \left(\frac{p_0 E \cos \theta}{kT} \right)} \quad (4.80)$$

where we have chosen \mathbf{E} along the z axis, integrated out all the irrelevant variables, and noted that only the component of $\langle \mathbf{p}_0 \rangle$ parallel to the field is different from zero. In general, $(p_0 E/kT)$ is very small compared to unity, except at low temperatures. Hence we can expand the exponentials and obtain the result:

$$\langle p_{\text{mol}} \rangle \approx \frac{1}{3} \frac{p_0^2}{kT} E \quad (4.81)$$

The orientation polarization depends inversely on the temperature, as might be expected of an effect in which the applied field must overcome the opposition of thermal agitation.

In general both types of polarization, induced (electronic and ionic) and

Fig. 4.10 Variation of molecular polarizability γ_{mol} with temperature for polar and nonpolar substances. γ_{mol} is plotted versus T^{-1} .

orientation, are present, and the general form of the molecular polarization is

$$\gamma_{\text{mol}} \approx \gamma_i + \frac{1}{3} \frac{p_0^2}{kT} \quad (4.82)$$

This shows a temperature dependence of the form $(a + b/T)$ so that the two types of polarization can be separated experimentally, as indicated in Fig. 4.10. For “polar” molecules, such as HCl and H₂O, the observed permanent dipole moments are of the order of an electronic charge times 10^{-8} cm, in accordance with molecular dimensions.

4.7 Electrostatic Energy in Dielectric Media

In Section 1.11 we discussed the energy of a system of charges in free space. The result obtained there,

$$W = \frac{1}{2} \int \rho(\mathbf{x}) \Phi(\mathbf{x}) d^3x \quad (4.83)$$

for the energy due to a charge density $\rho(\mathbf{x})$ and a potential $\Phi(\mathbf{x})$ cannot in general be taken over as it stands in our macroscopic description of dielectric media. The reason becomes clear when we recall how (4.83) was obtained. We thought of the final configuration of charge as being created by assembling bit by bit the elemental charges, bringing each one in from infinitely far away against the action of the then existing electric field. The total work done was given by (4.83). With dielectric media work is done not only to bring real (macroscopic) charge into position, but also to produce a certain state of polarization in the medium. If ρ and Φ in (4.83) represent macroscopic variables, it is certainly not evident that (4.83) represents the total work, including that done on the dielectric.

In order to be general in our description of dielectrics we will not initially

make any assumptions about linearity, uniformity, etc., of the response of a dielectric to an applied field. Rather, let us consider a small change in the energy δW due to some sort of change $\delta\rho$ in the macroscopic charge density ρ existing in all space. The work done to accomplish this change is

$$\delta W = \int \delta\rho(\mathbf{x})\Phi(\mathbf{x}) d^3x \quad (4.84)$$

where $\Phi(\mathbf{x})$ is the potential due to the charge density $\rho(\mathbf{x})$ already present. Since $\nabla \cdot \mathbf{D} = 4\pi\rho$, we can relate the change $\delta\rho$ to a change in the displacement of $\delta\mathbf{D}$:

$$\delta\rho = \frac{1}{4\pi} \nabla \cdot (\delta\mathbf{D}) \quad (4.85)$$

Then the energy change δW can be cast into the form:

$$\delta W = \frac{1}{4\pi} \int \mathbf{E} \cdot \delta\mathbf{D} d^3x \quad (4.86)$$

where we have used $\mathbf{E} = -\nabla\Phi$ and have assumed that $\rho(\mathbf{x})$ was a localized charge distribution. The total electrostatic energy can now be written down formally, at least, by allowing \mathbf{D} to be brought from an initial value $\mathbf{D} = 0$ to its final value \mathbf{D} :

$$W = \frac{1}{4\pi} \int d^3x \int_0^{\mathbf{D}} \mathbf{E} \cdot \delta\mathbf{D} \quad (4.87)$$

If the medium is *linear*, then

$$\mathbf{E} \cdot \delta\mathbf{D} = \frac{1}{2}\delta(\mathbf{E} \cdot \mathbf{D}) \quad (4.88)$$

and the total electrostatic energy is

$$W = \frac{1}{8\pi} \int \mathbf{E} \cdot \mathbf{D} d^3x \quad (4.89)$$

This last result can be transformed into (4.83) by using $\mathbf{E} = -\nabla\Phi$ and $\nabla \cdot \mathbf{D} = 4\pi\rho$, or by going back to (4.84) and assuming that ρ and Φ are connected linearly. Thus we see that (4.83) is *valid macroscopically only if the behavior is linear*. Otherwise the energy of a final configuration must be calculated from (4.87) and might conceivably depend on the past history of the system (hysteresis effects).

A problem of considerable interest is the change in energy when a dielectric object with a linear response is placed in an electric field whose sources are fixed. Suppose that initially the electric field \mathbf{E}_0 due to a certain distribution of charges $\rho_0(\mathbf{x})$ exists in a medium of dielectric constant ϵ_0 which may be a function of position. The initial electrostatic energy is

$$W_0 = \frac{1}{8\pi} \int \mathbf{E}_0 \cdot \mathbf{D}_0 d^3x$$

where $\mathbf{D}_0 = \epsilon_0 \mathbf{E}_0$. Then with the sources fixed in position a dielectric object of volume V_1 is introduced into the field, changing the field from \mathbf{E}_0 to \mathbf{E} . The presence of the object can be described by a dielectric constant $\epsilon(\mathbf{x})$, which has the value ϵ_1 inside V_1 and ϵ_0 outside V_1 . To avoid mathematical difficulties we can imagine $\epsilon(\mathbf{x})$ to be a smoothly varying function of position which falls rapidly but continuously from ϵ_1 to ϵ_0 at the edge of the volume V_1 . The energy now has the value

$$W_1 = \frac{1}{8\pi} \int \mathbf{E} \cdot \mathbf{D} \, d^3x$$

where $\mathbf{D} = \epsilon \mathbf{E}$. The difference in the energy can be written:

$$\begin{aligned} W &= \frac{1}{8\pi} \int (\mathbf{E} \cdot \mathbf{D} - \mathbf{E}_0 \cdot \mathbf{D}_0) \, d^3x \\ &= \frac{1}{8\pi} \int (\mathbf{E} \cdot \mathbf{D}_0 - \mathbf{D} \cdot \mathbf{E}_0) \, d^3x + \frac{1}{8\pi} \int (\mathbf{E} + \mathbf{E}_0) \cdot (\mathbf{D} - \mathbf{D}_0) \, d^3x \end{aligned} \quad (4.90)$$

The second integral can be shown to vanish by the following argument. Since $\nabla \times (\mathbf{E} + \mathbf{E}_0) = 0$, we can write

$$\mathbf{E} + \mathbf{E}_0 = -\nabla \Phi$$

Then the second integral becomes:

$$I = -\frac{1}{8\pi} \int \nabla \Phi \cdot (\mathbf{D} - \mathbf{D}_0) \, d^3x$$

Integration by parts transforms this into

$$I = \frac{1}{8\pi} \int \Phi \nabla \cdot (\mathbf{D} - \mathbf{D}_0) \, d^3x = 0$$

since $\nabla \cdot (\mathbf{D} - \mathbf{D}_0) = 0$ because the source charge density $\rho_0(\mathbf{x})$ is assumed unaltered by the insertion of the dielectric object. Consequently the energy change is

$$W = \frac{1}{8\pi} \int (\mathbf{E} \cdot \mathbf{D}_0 - \mathbf{D} \cdot \mathbf{E}_0) \, d^3x \quad (4.91)$$

The integration appears to be over all space, but is actually only over the volume V_1 of the object, since, outside V_1 , $\mathbf{D} = \epsilon_0 \mathbf{E}$. Therefore we can write

$$W = -\frac{1}{8\pi} \int_{V_1} (\epsilon_1 - \epsilon_0) \mathbf{E} \cdot \mathbf{E}_0 \, d^3x \quad (4.92)$$

If the medium surrounding the dielectric body is free space, then $\epsilon_0 = 1$. Using the definition of polarization \mathbf{P} , (4.92) can then be expressed in the form:

$$W = -\frac{1}{2} \int_{V_1} \mathbf{P} \cdot \mathbf{E}_0 \, d^3x \quad (4.93)$$

where \mathbf{P} is the polarization of the dielectric. This shows that the energy density of a dielectric placed in a field \mathbf{E}_0 whose sources are fixed is given by

$$w = -\frac{1}{2} \mathbf{P} \cdot \mathbf{E}_0 \quad (4.94)$$

This result is analogous to the dipole term in the energy (4.24) of a charge distribution in an external field. The factor $\frac{1}{2}$ is due to the fact that (4.94) represents the energy density of a polarizable dielectric in an external field, rather than a permanent dipole. It is the same factor $\frac{1}{2}$ which appears in (4.88).

Equations (4.92) and (4.93) show that a dielectric body will tend to move towards regions of increasing field \mathbf{E}_0 provided $\epsilon_1 > \epsilon_0$. To calculate the force acting we can imagine a small generalized displacement of the body $\delta\xi$. Then there will be a change in the energy δW . Since the charges are held fixed, there is no external source of energy and the change in field energy can be interpreted as a change in the potential energy of the body. This means that there is a force acting on the body:

$$F_\xi = - \left(\frac{\partial W}{\partial \xi} \right)_Q \quad (4.95)$$

where the subscript Q has been placed on the partial derivative to indicate that *the sources of the field are kept fixed*.

In practical situations involving the motion of dielectrics the electric fields are often produced by a configuration of electrodes held at *fixed potentials* by connection to an external source such as a battery. As the distribution of dielectric varies, charge will flow to or from the battery to the electrodes in order to maintain the potentials constant. This means that energy is being supplied from the external source, and it is of interest to compare the energy supplied in that way with the energy change found above *for fixed sources* of the field. We will treat only linear media so that (4.83) is valid. It is sufficient to consider small changes in an already existing configuration. From (4.83) it is evident that the change in energy accompanying the changes $\delta\rho(\mathbf{x})$ and $\delta\Phi(\mathbf{x})$ in charge density and potential is

$$\delta W = \frac{1}{2} \int (\rho \delta\Phi + \Phi \delta\rho) d^3x \quad (4.96)$$

Comparison with (4.84) shows that, if the dielectric properties are not changed, the two terms in (4.96) are equal. If, however, the dielectric properties are altered,

$$\epsilon(\mathbf{x}) \rightarrow \epsilon(\mathbf{x}) + \delta\epsilon(\mathbf{x}) \quad (4.97)$$

the contributions in (4.96) are not necessarily the same. In fact, we have just calculated the change in energy brought about by introducing a dielectric body into an electric field whose sources were fixed ($\delta\rho = 0$). Equal contributions in (4.96) would imply $\delta W = 0$, but (4.91) or (4.92) are not zero in general. The

reason for this difference is the existence of the polarization charge. The change in dielectric properties implied by (4.97) can be thought of as a change in the polarization-charge density. If then (4.96) is interpreted as an integral over both free and polarization-charge densities (i.e., a microscopic equation), the two contributions are always equal. However, it is often convenient to deal with macroscopic quantities. Then the equality holds only if the dielectric properties are unchanged.

The process of altering the dielectric properties in some way (by moving the dielectric bodies, by changing their susceptibilities, etc.) in the presence of electrodes at fixed potentials can be viewed as taking place in two steps. In the first step the electrodes are disconnected from the batteries and the charges on them held fixed ($\delta\rho=0$). With the change (4.97) in dielectric properties, the energy change is

$$\delta W_1 = \frac{1}{2} \int \rho \delta\Phi_1 d^3x \quad (4.98)$$

where $\delta\Phi_1$ is the change in potential produced. This can be shown to yield the result (4.92). In the second step the batteries are connected again to the electrodes to restore their potentials to the original values. There will be a flow of charge $\delta\rho_2$ from the batteries accompanying the change in potential* $\delta\Phi_2 = -\delta\Phi_1$. Therefore the energy change in the second step is

$$\delta W_2 = \frac{1}{2} \int (\rho \delta\Phi_2 + \Phi \delta\rho_2) d^3x = -2 \delta W_1 \quad (4.99)$$

since the two contributions are equal. In the second step we find the external sources changing the energy in the opposite sense and by twice the amount of the initial step. Consequently the net change is

$$\delta W = -\frac{1}{2} \int \rho \delta\Phi_1 d^3x \quad (4.100)$$

Symbolically

$$\delta W_v = -\delta W_o \quad (4.101)$$

where the subscript denotes the quantity held fixed. If a dielectric with $\epsilon > 1$ moves into a region of greater field strength, the energy increases instead of decreases. For a generalized displacement $d\xi$ the mechanical force acting is now

$$F_\xi = + \left(\frac{\partial W}{\partial \xi} \right)_v \quad (4.102)$$

* Note that it is necessary merely to know that $\delta\Phi_2 = -\delta\Phi_1$ on the electrodes, since that is the only place where free charge resides.

PROBLEMS

4.1 Calculate the multipole moments q_{lm} of the charge distributions shown below. Try to obtain results for the nonvanishing moments valid for all l , but in each case find the first two sets of nonvanishing moments at the very least.

Problem 4.1

(c) For the charge distribution (b) write down the multipole expansion for the potential. Keeping only the lowest-order term in the expansion, plot the potential in the x - y plane as a function of distance from the origin for distances greater than a .

(d) Calculate directly from Coulomb's law the exact potential for (b) in the x - y plane. Plot it as a function of distance and compare with the result found in (c).

Divide out the asymptotic form in parts (c) and (d) in order to see the behavior at large distances more clearly.

- 4.2 A point dipole with dipole moment \mathbf{p} is located at the point \mathbf{x}_0 . From the properties of the derivative of a Dirac delta function show that for calculation of the potential Φ or the energy of a dipole in an external field, the dipole can be described by an effective charge density

$$\rho_{\text{eff}}(\mathbf{x}) = -\mathbf{p} \cdot \nabla \delta(\mathbf{x} - \mathbf{x}_0)$$

- 4.3 The l th term in the multipole expansion (4.1) of the potential is specified by the $(2l+1)$ multipole moments q_{lm} . On the other hand, the Cartesian multipole moments,

$$Q_{\alpha\beta\gamma}^{(l)} = \int \rho(\mathbf{x}) x^\alpha y^\beta z^\gamma d^3x$$

with α, β, γ nonnegative integers subject to the constraint, $\alpha + \beta + \gamma = l$, are $(l+1)(l+2)/2$ in number. Thus, for $l > 1$ there are more Cartesian multipole moments than seem necessary to describe the term in the potential whose radial dependence is r^{l-1} .

Show that, while the q_{lm} transform under rotations as spherical tensors of rank l , the Cartesian multipole moments correspond to spherical tensors of ranks $l, l-2, l-4, \dots, l_{\min}$, where $l_{\min} = 0$ or 1 for l even or odd, respectively. Check that the number of different tensorial components adds up to the total number of Cartesian tensors. Why are only the q_{lm} needed in the expansion (4.1)?

- 4.4 (a) Prove the following theorem:

For an arbitrary charge distribution $\rho(\mathbf{x})$ the values of the $(2l+1)$ moments of the first nonvanishing multipole are independent of the origin of the coordinate axes, but the values of all higher multipole moments do in general depend on the choice of origin. (The different moments q_{lm} for fixed l depend, of course, on the orientation of the axes.)

(b) A charge distribution has multipole moments $q, \mathbf{p}, Q_{ij}, \dots$ with respect to one set of coordinate axes, and moments $q', \mathbf{p}', Q'_{ij}, \dots$ with respect to another set whose axes are parallel to the first, but whose origin is located at the point $\mathbf{R} = (X, Y, Z)$ relative to the first. Determine explicitly the connections between the monopole, dipole, and quadrupole moments in the two coordinate frames.

(c) If $q \neq 0$, can \mathbf{R} be found so that $\mathbf{p}' = 0$? If $q \neq 0, \mathbf{p} \neq 0$, or at least $\mathbf{p} \neq 0$, can \mathbf{R} be found so that $Q'_{ij} = 0$?

- 4.5 A localized charge density $\rho(x, y, z)$ is placed in an external electrostatic field described by a potential $\Phi^{(0)}(x, y, z)$. The external potential varies slowly in space over the region where the charge density is different from zero.

(a) From first principles calculate the total *force* acting on the charge distribution as an expansion in multipole moments times derivatives of the electric field, up to and including the quadrupole moments. Show that the force is

$$\mathbf{F} = q\mathbf{E}^{(0)}(0) + \{\nabla[\mathbf{p} \cdot \mathbf{E}^{(0)}(\mathbf{x})]\}_0 + \left\{ \nabla \left[\frac{1}{6} \sum_{j,k} Q_{jk} \frac{\partial E_j^{(0)}}{\partial x_k}(\mathbf{x}) \right] \right\}_0 + \dots$$

Compare this to the expansion (4.24) of the energy W . Note that (4.24) is a number—it is not a function of \mathbf{x} that can be differentiated! What is its connection to \mathbf{F} ?

(b) Repeat the calculation of (a) for the total *torque*. For simplicity, evaluate only one Cartesian component of the torque, say N_1 . Show that this component is

$$N_1 = [\mathbf{p} \times \mathbf{E}^{(0)}(0)]_1 + \frac{1}{3} \left[\frac{\partial}{\partial x_3} \left(\sum_j Q_{2j} E_j^{(0)} \right) - \frac{\partial}{\partial x_2} \left(\sum_j Q_{3j} E_j^{(0)} \right) \right]_0 + \dots$$

- 4.6 A nucleus with quadrupole moment Q finds itself in a cylindrically symmetric electric field with a gradient $(\partial E_z/\partial z)_0$ along the z axis at the position of the nucleus.

(a) Show that the energy of quadrupole interaction is

$$W = -\frac{e}{4} Q \left(\frac{\partial E_z}{\partial z} \right)_0$$

(b) If it is known that $Q = 2 \times 10^{-24} \text{ cm}^2$ and that W/h is 10 MHz, where h is Planck's constant, calculate $(\partial E_z/\partial z)_0$ in units of e/a_0^3 , where $a_0 = \hbar^2/me^2 = 0.529 \times 10^{-8} \text{ cm}$ is the Bohr radius in hydrogen.

(c) Nuclear charge distributions can be approximated by a constant charge density throughout a spheroidal volume of semimajor axis a and semiminor axis b . Calculate the quadrupole moment of such a nucleus, assuming that the total charge is Ze . Given that Eu^{153} ($Z = 63$) has a quadrupole moment $Q = 2.5 \times 10^{-24} \text{ cm}^2$ and a mean radius

$$R = (a+b)/2 = 7 \times 10^{-13} \text{ cm}$$

determine the fractional difference in radius $(a-b)/R$.

- 4.7 A localized distribution of charge has a charge density

$$\rho(\mathbf{r}) = \frac{1}{64\pi} r^2 e^{-r} \sin^2 \theta$$

(a) Make a multipole expansion of the potential due to this charge density and determine all the nonvanishing multipole moments. Write down the potential at large distances as a finite expansion in Legendre polynomials.

(b) Determine the potential explicitly at any point in space, and show that near the origin, correct to r^2 inclusive,

$$\Phi(\mathbf{r}) \approx \frac{1}{4} - \frac{r^2}{120} P_2(\cos \theta)$$

(c) If there exists at the origin a nucleus with a quadrupole moment $Q = 10^{-24} \text{ cm}^2$, determine the magnitude of the interaction energy, assuming that the unit of charge in $\rho(\mathbf{r})$ above is the electronic charge and the unit of length is the hydrogen Bohr radius $a_0 = \hbar^2/me^2 = 0.529 \times 10^{-8} \text{ cm}$. Express your answer as a frequency by dividing by Planck's constant h .

The charge density in this problem is that for the $m = \pm 1$ states of the $2p$ level in hydrogen, while the quadrupole interaction is of the same order as found in molecules.

- 4.8 A very long, right circular, cylindrical shell of dielectric constant ϵ and inner and outer radii a and b , respectively, is placed in a previously uniform electric field E_0 with its axis perpendicular to the field. The medium inside and outside the cylinder has a dielectric constant of unity.

(a) Determine the potential and electric field in the three regions, neglecting end effects.

(b) Sketch the lines of force for a typical case of $b \approx 2a$.

(c) Discuss the limiting forms of your solution appropriate for a solid dielectric cylinder in a uniform field, and a cylindrical cavity in a uniform dielectric.

- 4.9 A point charge q is located in free space a distance d from the center of a dielectric sphere of radius a ($a < d$) and dielectric constant ϵ .

(a) Find the potential at all points in space as an expansion in spherical harmonics.

(b) Calculate the rectangular components of the electric field *near* the center of the sphere.

(c) Verify that, in the limit $\epsilon \rightarrow \infty$, your result is the same as that for the conducting sphere.

- 4.10 Two concentric conducting spheres of inner and outer radii a and b , respectively, carry charges $\pm Q$. The empty space between the spheres is half-filled by a hemispherical shell of dielectric (of dielectric constant ϵ), as shown in the figure.

Problem 4.10

- (a) Find the electric field everywhere between the spheres.
 (b) Calculate the surface-charge distribution on the inner sphere.
 (c) Calculate the polarization-charge density induced on the surface of the dielectric at $r = a$.

- 4.11 The following data on the variation of dielectric constant with pressure are taken from the *Smithsonian Physical Tables*, 9th ed., p. 424:

Air at 292°K

Pressure (atm)	ϵ	
20	1.0108	Relative density of air as a function of pressure is given in <i>AIP Handbook</i> , 3rd ed., 1972, p. 4-165.
40	1.0218	
60	1.0333	
80	1.0439	
100	1.0548	

Pentane (C_5H_{12}) at 303°K

Pressure (atm)	Density (gm/cm ³)	ϵ
1	0.613	1.82
10^3	0.701	1.96
4×10^3	0.796	2.12
8×10^3	0.865	2.24
12×10^3	0.907	2.33

Test the Clausius-Mossotti relation between dielectric constant and density for air and pentane in the ranges tabulated. Does it hold exactly? Approximately? If approximately, discuss fractional variations in density and $(\epsilon - 1)$. For pentane, compare the Clausius-Mossotti relation to the cruder relation, $(\epsilon - 1) \propto \text{density}$.

- 4.12 Water vapor is a polar gas whose dielectric constant exhibits an appreciable temperature dependence. The following table gives experimental data on this effect. Assuming that water vapor obeys the ideal gas law, calculate the molecular polarizability as a function of inverse temperature and plot it. From the slope of the curve,

deduce a value for the permanent dipole moment of the H_2O molecule (express the dipole moment in esu—stat-coulomb-centimeters).

T (°K)	Pressure (cm Hg)	$(\epsilon - 1) \times 10^5$
393	56.49	400.2
423	60.93	371.7
453	65.34	348.8
483	69.75	328.7

- 4.13 Two long, coaxial, cylindrical conducting surfaces of radii a and b are lowered vertically into a liquid dielectric. If the liquid rises a distance h between the electrodes when a potential difference V is established between them, show that the susceptibility of the liquid is

$$\chi_e = \frac{(b^2 - a^2) \rho g h \ln(b/a)}{V^2}$$

where ρ is the density of the liquid, g is the acceleration due to gravity, and the susceptibility of air is neglected.

5

Magnetostatics

5.1 Introduction and Definitions

In the preceding chapters various aspects of electrostatics (i.e., the fields and interactions of stationary charges and boundaries) have been studied. We now turn to steady-state magnetic phenomena. From an historical point of view, magnetic phenomena have been known and studied for at least as long as electric phenomena. Lodestones were known in ancient times; the mariner's compass is a very old invention; Gilbert's researches on the earth as a giant magnet date from before 1600. In contrast to electrostatics, the basic laws of magnetic fields did not follow straightforwardly from man's earliest contact with magnetic materials. The reasons are several, but they all stem from the radical difference between magnetostatics and electrostatics: *there are no free magnetic charges*. This means that magnetic phenomena are quite different from electric phenomena and that for a long time no connection was established between them. The basic entity in magnetic studies was what we now know as a magnetic dipole. In the presence of magnetic materials the dipole tends to align itself in a certain direction. That direction is by definition the direction of the magnetic-flux density, denoted by \mathbf{B} , provided the dipole is sufficiently small and weak that it does not perturb the existing field. The magnitude of the flux density can be defined by the mechanical torque \mathbf{N} exerted on the magnetic dipole:

$$\mathbf{N} = \boldsymbol{\mu} \times \mathbf{B} \quad (5.1)$$

where $\boldsymbol{\mu}$ is the magnetic moment of the dipole, defined in some suitable set of units.

Already, in the definition of the magnetic-flux density \mathbf{B} (sometimes called the *magnetic induction*), we have a more complicated situation than for the electric field. Further quantitative elucidation of magnetic phenomena did not occur until the connection between currents and magnetic fields was established. A

current corresponds to charges in motion and is described by a current density \mathbf{J} , measured in units of positive charge crossing unit area per unit time, the direction of motion of the charges defining the direction of \mathbf{J} . In electrostatic units, current density is measured in statcoulombs per square centimeter-second, and is sometimes called statamperes per square centimeter, while in MKSA units it is measured in coulombs per square meter-second or amperes per square meter. If the current density is confined to wires of small cross section, we usually integrate over the cross-sectional area and speak of a current of so many statamperes or amperes flowing along the wire.

Conservation of charge demands that the charge density at any point in space be related to the current density in that neighborhood by a continuity equation:

$$\frac{\partial \rho}{\partial t} + \nabla \cdot \mathbf{J} = 0 \quad (5.2)$$

This expresses the physical fact that a decrease in charge inside a small volume with time must correspond to a flow of charge out through the surface of the small volume, since the total amount of charge must be conserved. Steady-state magnetic phenomena are characterized by no change in the net charge density anywhere in space. Consequently in magnetostatics

$$\nabla \cdot \mathbf{J} = 0 \quad (5.3)$$

We now proceed to discuss the experimental connection between current and magnetic-flux density and to establish the basic laws of magnetostatics.

5.2 Biot and Savart Law

In 1819 Oersted observed that wires carrying electric currents produced deflections of permanent magnetic dipoles placed in their neighborhood. Thus the currents were sources of magnetic-flux density. Biot and Savart (1820), first, and Ampère (1820–1825), in much more elaborate and thorough experiments, established the basic experimental laws relating the magnetic induction \mathbf{B} to the currents and established the law of force between one current and another. Although not in the form in which Ampère deduced it, the basic relation is the following. If $d\mathbf{l}$ is an element of length (pointing in the direction of current flow) of a filamentary wire which carries a current I and \mathbf{x} is the coordinate vector from the element of length to an observation point P , as shown in Fig. 5.1, then the elemental flux density $d\mathbf{B}$ at the point P is given in magnitude and direction by

$$d\mathbf{B} = kI \frac{(d\mathbf{l} \times \mathbf{x})}{|\mathbf{x}|^3} \quad (5.4)$$

It should be noted that (5.4) is an inverse square law, just as is Coulomb's law of electrostatics. However, the vector character is very different.

Fig. 5.1 Elemental magnetic induction $d\mathbf{B}$ due to current element $I d\mathbf{l}$.

A word of caution about (5.4). There is a temptation to think of (5.4) as the magnetic equivalent of the electric field (1.3) of a point charge and to identify $I d\mathbf{l}$ as the analog of q . Strictly speaking this is incorrect. Equation (5.4) has meaning only as one element of a sum over a continuous set, the sum representing the magnetic induction of a current loop or circuit. Obviously the continuity equation (5.3) is not satisfied for the current element $I d\mathbf{l}$ standing alone—the current comes from nowhere and disappears after traversing the length $d\mathbf{l}$! One apparent way out of this difficulty is to realize that current is actually charge in motion and to replace $I d\mathbf{l}$ by $q\mathbf{v}$ where q is the charge and \mathbf{v} its velocity. The flux density for such a charge in motion would be

$$\mathbf{B} = kq \frac{\mathbf{v} \times \mathbf{x}}{|\mathbf{x}|^3} \quad (5.5)$$

in close correspondence with (5.4). But this expression is time-dependent and furthermore is valid only for charges whose velocities are small compared to that of light and whose accelerations can be neglected. Since we are considering steady-state magnetic fields in this chapter we stick with (5.4) and integrate over circuits to obtain physical results.*

In (5.4) and (5.5) the constant k depends on the system of units used, as discussed in detail in the Appendix. If current is measured in esu, but the flux density is measured in emu, the constant is $k = 1/c$, where c is found experimentally to be equal to the velocity of light in *vacuo* ($c = 2.998 \times 10^{10}$ cm/sec). This system of units is called the Gaussian system. To insert the velocity of light into our equations at this stage seems a little artificial, but not if we consider electromagnetism from the point of view of special relativity. As is discussed in

* There is an apparent inconsistency here. Currents are, after all, charges in motion. How can (5.4), integrated, yield exact results yet (5.5) be only approximate? The answer is that (5.5) applies to only one charge. If a system of many charges moves in such a way that as the unit of charge goes to zero and the number of charges goes to infinity it produces a steady current flow, then the sum of the exact relativistic fields, *including acceleration effects*, gives a magnetostatic field equal to the field obtained by integrating (5.4) over the current. This rather subtle result is discussed for some special situations in Problems 14.12 and 14.13.

detail in Chapter 11, \mathbf{E} and \mathbf{B} must be considered as different elements of the field-strength tensor $F_{\alpha\beta}$. A charge at rest in one frame has only an electrostatic field in that frame, but in a moving frame it is associated with a magnetic flux density (5.5), with $k = 1/c$ in the customary usage. The ratio v/c appears naturally in relativistic considerations. The choice of $k = 1/c$ also has the related advantage of measuring charge and current in a consistent set of units so that the continuity equation (5.2) retains its simple form, without factors of c . We will adopt the Gaussian system here.

We can linearly superpose the basic magnetic flux elements (5.4) by integration to determine the magnetic-flux density due to various configurations of current-carrying wires. For example, the magnetic induction \mathbf{B} of the long straight wire shown in Fig. 5.2 carrying a current I can be seen to be directed along the normal to the plane containing the wire and the observation point, so that the lines of magnetic induction are concentric circles around the wire. The magnitude of \mathbf{B} is given by

$$|\mathbf{B}| = \frac{IR}{c} \int_{-\infty}^{\infty} \frac{dl}{(R^2 + l^2)^{3/2}} = \frac{2I}{cR} \quad (5.6)$$

where R is the distance from the observation point to the wire. This is the experimental result first found by Biot and Savart and is known as the Biot-Savart law. Note that the magnitude of the induction \mathbf{B} varies with R in the same way as the electric field due to a long line charge of uniform linear-charge density. This analogy shows that in some circumstances there may be a correspondence between electrostatic and magnetostatic problems, even though the vector character of the fields is different. We shall see more of that in later sections.

Ampère's experiments did not deal directly with the determination of the relation between currents and magnetic induction, but were concerned rather with the force that one current-carrying wire experiences in the presence of another. Since we have already introduced the idea that a current element

Fig. 5.2

produces a magnetic induction, we phrase the force law as the force experienced by a current element $I_1 d\mathbf{l}_1$ in the presence of a magnetic induction \mathbf{B} . The elemental force is

$$d\mathbf{F} = \frac{I_1}{c} (d\mathbf{l}_1 \times \mathbf{B}) \quad (5.7)$$

I_1 is the current in the element (measured in esu), \mathbf{B} is the flux density (in emu), and c is the velocity of light. If the external field \mathbf{B} is due to a closed current loop #2 with current I_2 , then the total force which a closed current loop #1 with current I_1 experiences is [from (5.4) and (5.7)]:

$$\mathbf{F}_{12} = \frac{I_1 I_2}{c^2} \oint \oint \frac{d\mathbf{l}_1 \times (d\mathbf{l}_2 \times \mathbf{x}_{12})}{|\mathbf{x}_{12}|^3} \quad (5.8)$$

The line integrals are taken around the two loops; \mathbf{x}_{12} is the vector distance from line element $d\mathbf{l}_2$ to $d\mathbf{l}_1$, as shown in Fig. 5.3. This is the mathematical statement of Ampère's observations about forces between current-carrying loops. By manipulating the integrand it can be put in a form which is symmetric in $d\mathbf{l}_1$ and $d\mathbf{l}_2$ and which explicitly satisfies Newton's third law. Thus

$$\frac{d\mathbf{l}_1 \times (d\mathbf{l}_2 \times \mathbf{x}_{12})}{|\mathbf{x}_{12}|^3} = -(d\mathbf{l}_1 \cdot d\mathbf{l}_2) \frac{\mathbf{x}_{12}}{|\mathbf{x}_{12}|^3} + d\mathbf{l}_2 \left(\frac{d\mathbf{l}_1 \cdot \mathbf{x}_{12}}{|\mathbf{x}_{12}|^3} \right) \quad (5.9)$$

The second term involves a perfect differential in the integral over $d\mathbf{l}_1$. Consequently it gives no contribution to the integral (5.8), provided the paths are closed or extend to infinity. Then Ampère's law of force between current loops becomes

$$\mathbf{F}_{12} = -\frac{I_1 I_2}{c^2} \oint \oint \frac{(d\mathbf{l}_1 \cdot d\mathbf{l}_2) \mathbf{x}_{12}}{|\mathbf{x}_{12}|^3} \quad (5.10)$$

showing symmetry in the integration, apart from the necessary vectorial dependence on \mathbf{x}_{12} .

Each of two long, parallel, straight wires a distance d apart, carrying currents I_1 and I_2 , experiences a force per unit length directed perpendicularly towards

Fig. 5.3 Two Ampèrian current loops.

the other wire and of magnitude,

$$\frac{dF}{dl} = \frac{2I_1 I_2}{c^2 d} \quad (5.11)$$

The force is attractive (repulsive) if the currents flow in the same (opposite) directions. The forces which exist between current-carrying wires can be used to define magnetic-flux density in a way that is independent of permanent magnetic dipoles.* We will see later that the torque expression (5.1) and the force result (5.7) are intimately related.

If a current density $\mathbf{J}(\mathbf{x})$ is in an external magnetic-flux density $\mathbf{B}(\mathbf{x})$, the elementary force law implies that the total force on the current distribution is

$$\mathbf{F} = \frac{1}{c} \int \mathbf{J}(\mathbf{x}) \times \mathbf{B}(\mathbf{x}) d^3x \quad (5.12)$$

Similarly the total torque is

$$\mathbf{N} = \frac{1}{c} \int \mathbf{x} \times (\mathbf{J} \times \mathbf{B}) d^3x \quad (5.13)$$

These general results will be applied to localized current distributions in Section 5.7.

5.3 The Differential Equations of Magnetostatics and Ampère's Law

The basic law (5.4) for the magnetic induction can be written down in general form for a current density $\mathbf{J}(\mathbf{x})$:

$$\mathbf{B}(\mathbf{x}) = \frac{1}{c} \int \mathbf{J}(\mathbf{x}') \times \frac{(\mathbf{x} - \mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|^3} d^3x' \quad (5.14)$$

This expression for $\mathbf{B}(\mathbf{x})$ is the magnetic analog of electric field in terms of the charge density:

$$\mathbf{E}(\mathbf{x}) = \int \rho(\mathbf{x}') \frac{(\mathbf{x} - \mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|^3} d^3x' \quad (5.15)$$

Just as this result for \mathbf{E} was not as convenient in some situations as differential equations, so (5.14) is not the most useful form for magnetostatics, even though it contains in principle a description of all the phenomena.

In order to obtain the differential equations equivalent to (5.14) we use the

* In fact, (5.11) is the basis of the internationally accepted standard of current (actually I/c here). See the Appendix.

relation just above (1.15) to transform (5.14) into the form:

$$\mathbf{B}(\mathbf{x}) = \frac{1}{c} \nabla \times \int \frac{\mathbf{J}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3x' \quad (5.16)$$

From (5.16) it follows immediately that the divergence of \mathbf{B} vanishes:

$$\nabla \cdot \mathbf{B} = 0 \quad (5.17)$$

This is the first equation of magnetostatics and corresponds to $\nabla \times \mathbf{E} = 0$ in electrostatics. By analogy with electrostatics we now calculate the curl of \mathbf{B} :

$$\nabla \times \mathbf{B} = \frac{1}{c} \nabla \times \nabla \times \int \frac{\mathbf{J}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3x' \quad (5.18)$$

With the identity $\nabla \times (\nabla \times \mathbf{A}) = \nabla(\nabla \cdot \mathbf{A}) - \nabla^2 \mathbf{A}$ for an arbitrary vector field \mathbf{A} , expression (5.18) can be transformed into

$$\nabla \times \mathbf{B} = \frac{1}{c} \nabla \int \mathbf{J}(\mathbf{x}') \cdot \nabla \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) d^3x' - \frac{1}{c} \int \mathbf{J}(\mathbf{x}') \nabla^2 \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) d^3x' \quad (5.19)$$

Using the fact that

$$\nabla \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) = -\nabla' \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right)$$

and

$$\nabla^2 \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) = -4\pi \delta(\mathbf{x} - \mathbf{x}')$$

the integrals in (5.19) can be written:

$$\nabla \times \mathbf{B} = -\frac{1}{c} \nabla \int \mathbf{J}(\mathbf{x}') \cdot \nabla' \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) d^3x' + \frac{4\pi}{c} \mathbf{J}(\mathbf{x}) \quad (5.20)$$

Integration by parts yields

$$\nabla \times \mathbf{B} = \frac{4\pi}{c} \mathbf{J} + \frac{1}{c} \nabla \int \frac{\nabla' \cdot \mathbf{J}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3x' \quad (5.21)$$

But for steady-state magnetic phenomena $\nabla \cdot \mathbf{J} = 0$, so that we obtain

$$\nabla \times \mathbf{B} = \frac{4\pi}{c} \mathbf{J} \quad (5.22)$$

This is the second equation of magnetostatics, corresponding to $\nabla \cdot \mathbf{E} = 4\pi\rho$ in electrostatics.

In electrostatics Gauss's law (1.11) is the integral form of the equation $\nabla \cdot \mathbf{E} = 4\pi\rho$. The integral equivalent of (5.22) is called *Ampère's law*. It is obtained by applying Stokes's theorem to the integral of the normal component of (5.22) over an open surface S bounded by a closed curve C , as shown in Fig.

Fig. 5.4

5.4. Thus

$$\int_S \nabla \times \mathbf{B} \cdot \mathbf{n} \, da = \frac{4\pi}{c} \int_S \mathbf{J} \cdot \mathbf{n} \, da \quad (5.23)$$

is transformed into

$$\oint_C \mathbf{B} \cdot d\mathbf{l} = \frac{4\pi}{c} \int_S \mathbf{J} \cdot \mathbf{n} \, da \quad (5.24)$$

Since the surface integral of the current density is the total current I passing through the closed curve C , Ampère's law can be written in the form:

$$\oint_C \mathbf{B} \cdot d\mathbf{l} = \frac{4\pi}{c} I \quad (5.25)$$

Just as Gauss's law can be used for calculation of the electric field in highly symmetric situations, so Ampère's law can be employed in analogous circumstances.

5.4 Vector Potential

The basic differential laws of magnetostatics are

$$\left. \begin{aligned} \nabla \times \mathbf{B} &= \frac{4\pi}{c} \mathbf{J} \\ \nabla \cdot \mathbf{B} &= 0 \end{aligned} \right\} \quad (5.26)$$

The problem is how to solve them. If the current density is zero in the region of interest, $\nabla \times \mathbf{B} = 0$ permits the expression of the vector magnetic induction \mathbf{B} as the gradient of a *magnetic scalar potential*, $\mathbf{B} = -\nabla \Phi_M$. Then (5.26) reduces to the Laplace equation for Φ_M , and all our techniques for handling electrostatic problems can be brought to bear. There are a large number of problems which fall into this class, but we will defer discussion of them until later in the chapter. The reason is that the boundary conditions are different from those encountered

in electrostatics, and the problems usually involve macroscopic media with magnetic properties different from free space with charges and currents.

A general method of attack is to exploit the second equation in (5.26). If $\nabla \cdot \mathbf{B} = 0$ everywhere, \mathbf{B} must be the curl of some vector field $\mathbf{A}(\mathbf{x})$, called the *vector potential*,

$$\mathbf{B}(\mathbf{x}) = \nabla \times \mathbf{A}(\mathbf{x}) \quad (5.27)$$

We have, in fact, already written \mathbf{B} in this form (5.16). Evidently, from (5.16), the general form of \mathbf{A} is

$$\mathbf{A}(\mathbf{x}) = \frac{1}{c} \int \frac{\mathbf{J}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3x' + \nabla \Psi(\mathbf{x}) \quad (5.28)$$

The added gradient of an arbitrary scalar function Ψ shows that, for a given magnetic induction \mathbf{B} , the vector potential can be freely transformed according to

$$\mathbf{A} \rightarrow \mathbf{A} + \nabla \Psi \quad (5.29)$$

This transformation is called a *gauge transformation*. Such transformations on \mathbf{A} are possible because (5.27) specifies only the curl of \mathbf{A} . The freedom of gauge transformations allows us to make $\nabla \cdot \mathbf{A}$ have any convenient functional form we wish.

If (5.27) is substituted into the first equation in (5.26), we find

$$\left. \begin{aligned} \nabla \times (\nabla \times \mathbf{A}) &= \frac{4\pi}{c} \mathbf{J} \\ \nabla (\nabla \cdot \mathbf{A}) - \nabla^2 \mathbf{A} &= \frac{4\pi}{c} \mathbf{J} \end{aligned} \right\} \quad (5.30)$$

or

If we now exploit the freedom implied by (5.29), we can make the convenient choice of gauge,* $\nabla \cdot \mathbf{A} = 0$. Then each rectangular component of the vector potential satisfies the Poisson equation,

$$\nabla^2 \mathbf{A} = -\frac{4\pi}{c} \mathbf{J} \quad (5.31)$$

From our discussions of electrostatics it is clear that the solution for \mathbf{A} in unbounded space is (5.28) with $\Psi = \text{constant}$:

$$\mathbf{A}(\mathbf{x}) = \frac{1}{c} \int \frac{\mathbf{J}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3x' \quad (5.32)$$

The condition $\Psi = \text{constant}$ can be understood as follows. Our choice of gauge, $\nabla \cdot \mathbf{A} = 0$, reduces to $\nabla^2 \Psi = 0$, since the first term in (5.28) has zero divergence

*The choice is called the *Coulomb gauge*, for a reason which will become apparent only in Section 6.5.

because of $\nabla' \cdot \mathbf{J} = 0$. If $\nabla^2 \Psi = 0$ holds in all space, Ψ must be at most a constant provided there are no sources at infinity.

5.5 Vector Potential and Magnetic Induction for a Circular Current Loop

As an illustration of the calculation of magnetic fields from given current distributions we consider the problem of a circular loop of radius a , lying in the x - y plane, centered at the origin, and carrying a current I , as shown in Fig. 5.5. The current density \mathbf{J} has only a component in the ϕ direction,

$$J_\phi = I \sin \theta' \delta(\cos \theta') \frac{\delta(r' - a)}{a} \quad (5.33)$$

The delta functions restrict current flow to a ring of radius a . The vectorial current density \mathbf{J} can be written

$$\mathbf{J} = -J_\phi \sin \phi' \mathbf{i} + J_\phi \cos \phi' \mathbf{j} \quad (5.34)$$

Since the geometry is cylindrically symmetric, we may choose the observation point in the x - z plane ($\phi = 0$) for purposes of calculation. Since the azimuthal integration in (5.32) is symmetric about $\phi' = 0$, the x component of the current does not contribute. This leaves only the y component, which is A_ϕ . Thus

$$A_\phi(r, \theta) = \frac{I}{ca} \int r'^2 dr' d\Omega' \frac{\sin \theta' \cos \phi' \delta(\cos \theta') \delta(r' - a)}{|\mathbf{x} - \mathbf{x}'|} \quad (5.35)$$

where $|\mathbf{x} - \mathbf{x}'| = [r^2 + r'^2 - 2rr'(\cos \theta \cos \theta' + \sin \theta \sin \theta' \cos \phi')]^{1/2}$.

We first consider the straightforward evaluation of (5.35). Integration over the delta functions leaves the result

$$A_\phi(r, \theta) = \frac{Ia}{c} \int_0^{2\pi} \frac{\cos \phi' d\phi'}{(a^2 + r^2 - 2ar \sin \theta \cos \phi')^{1/2}} \quad (5.36)$$

Fig. 5.5

This integral can be expressed in terms of the complete elliptic integrals K and E :

$$A_\phi(r, \theta) = \frac{4Ia}{c\sqrt{a^2 + r^2 + 2ar \sin \theta}} \left[\frac{(2 - k^2)K(k) - 2E(k)}{k^2} \right] \quad (5.37)$$

where the argument of the elliptic integrals is

$$k^2 = \frac{4ar \sin \theta}{a^2 + r^2 + 2ar \sin \theta}$$

The components of magnetic induction,

$$\left. \begin{aligned} B_r &= \frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} (\sin \theta A_\phi) \\ B_\theta &= -\frac{1}{r} \frac{\partial}{\partial r} (r A_\phi) \\ B_\phi &= 0 \end{aligned} \right\} \quad (5.38)$$

can also be expressed in terms of elliptic integrals. But the results are not particularly illuminating (useful, however, for computation).

For small k^2 , corresponding to $a \gg r$, $a \ll r$, or $\theta \ll 1$, the square bracket in (5.37) reduces to $(\pi k^2/16)$. Then the vector potential becomes approximately

$$A_\phi(r, \theta) = \frac{I\pi a^2}{c} \frac{r \sin \theta}{(a^2 + r^2 + 2ar \sin \theta)^{3/2}} \quad (5.39)$$

The corresponding fields are

$$\left. \begin{aligned} B_r &\simeq \frac{I\pi a^2}{c} \cos \theta \frac{(2a^2 + 2r^2 + ar \sin \theta)}{(a^2 + r^2 + 2ar \sin \theta)^{5/2}} \\ B_\theta &\simeq -\frac{I\pi a^2}{c} \sin \theta \frac{(2a^2 - r^2 + ar \sin \theta)}{(a^2 + r^2 + 2ar \sin \theta)^{5/2}} \end{aligned} \right\} \quad (5.40)$$

These can easily be specialized to the three regions, near the axis ($\theta \ll 1$), near the center of the loop ($r \ll a$), and far from the loop ($r \gg a$).

Of particular interest are the fields far from the loop:

$$\left. \begin{aligned} B_r &= 2 \left(\frac{I\pi a^2}{c} \right) \frac{\cos \theta}{r^3} \\ B_\theta &= \left(\frac{I\pi a^2}{c} \right) \frac{\sin \theta}{r^3} \end{aligned} \right\} \quad (5.41)$$

Comparison with the electrostatic dipole fields (4.12) shows that the magnetic fields far away from a circular current loop are dipole in character. By analogy with electrostatics we define the magnetic dipole moment of the loop to be

$$m = \frac{\pi I a^2}{c} \quad (5.42)$$

We will see in the next section that this is a special case of a general result—localized current distributions give dipole fields at large distances; the magnetic moment of a plane current loop is the product of the area of the loop times I/c .

Although we have obtained a complete solution to the problem in terms of elliptic integrals, we now illustrate the use of a spherical harmonic expansion to point out similarities and differences between the magnetostatic and electrostatic problems. Thus we return to (5.35) and substitute the spherical expansion (3.70) for $|\mathbf{x}-\mathbf{x}'|^{-1}$:

$$A_\phi = \frac{4\pi I}{ca} \operatorname{Re} \sum_{l,m} \frac{Y_{lm}(\theta, 0)}{2l+1} \int r'^2 dr' d\Omega' \delta(\cos \theta') \delta(r' - a) e^{i\phi'} \frac{r'_<}{r'_>^{l+1}} Y_{lm}^*(\theta', \phi') \quad (5.43)$$

The presence of $e^{i\phi'}$ means that only $m = +1$ will contribute to the sum. Hence

$$A_\phi = \frac{8\pi^2 Ia}{c} \sum_{l=1}^{\infty} \frac{Y_{l1}(\theta, 0)}{2l+1} \frac{r'_<}{r'_>^{l+1}} \left[Y_{l1} \left(\frac{\pi}{2}, 0 \right) \right] \quad (5.44)$$

where now $r_<$ ($r_>$) is the smaller (larger) of a and r . The square-bracketed quantity is a number depending on l :

$$\left[\right] = \sqrt{\frac{2l+1}{4\pi l(l+1)}} P_l^1(0) = \begin{cases} 0, & \text{for } l \text{ even} \\ \sqrt{\frac{2l+1}{4\pi l(l+1)}} \left[\frac{(-1)^{n+1} \Gamma(n+\frac{3}{2})}{\Gamma(n+1) \Gamma(\frac{3}{2})} \right], & \text{for } l = 2n+1 \end{cases} \quad (5.45)$$

Then A_ϕ can be written

$$A_\phi = -\frac{\pi Ia}{c} \sum_{n=0}^{\infty} \frac{(-1)^n (2n-1)!!}{2^n (n+1)!} \frac{r_<^{2n+1}}{r_>^{2n+2}} P_{2n+1}^1(\cos \theta) \quad (5.46)$$

where $(2n-1)!! = (2n-1)(2n-3)(\cdots) \times 5 \times 3 \times 1$, and the $n=0$ coefficient in the sum is unity by definition. To evaluate the radial component of \mathbf{B} from (5.38) we need

$$\frac{d}{dx} [\sqrt{1-x^2} P_l^1(x)] = l(l+1) P_l(x) \quad (5.47)$$

Then we find

$$B_r = \frac{2\pi Ia}{cr} \sum_{n=0}^{\infty} \frac{(-1)^n (2n+1)!!}{2^n n!} \frac{r_<^{2n+1}}{r_>^{2n+2}} P_{2n+1}(\cos \theta) \quad (5.48)$$

The θ component of \mathbf{B} is similarly

$$B_\theta = -\frac{\pi Ia^2}{c} \sum_{n=0}^{\infty} \frac{(-1)^n (2n+1)!!}{2^n (n+1)!} \left\{ -\left(\frac{2n+2}{2n+1} \right) \frac{1}{a^3} \left(\frac{r}{a} \right)^{2n} \right. \\ \left. \frac{1}{r^3} \left(\frac{a}{r} \right)^{2n} \right\} P_{2n+1}^1(\cos \theta) \quad (5.49)$$

The upper line holds for $r < a$, and the lower line for $r > a$. For $r \gg a$, only the $n=0$ term in the series is important. Then, since $P_1^1(\cos \theta) = -\sin \theta$, (5.48) and (5.49) reduce to (5.41). For $r \ll a$, the leading term is again $n=0$. The fields are then equivalent to a magnetic induction $2\pi I/ac$ in the z direction, a result that can be found by elementary means.

We note a characteristic difference between this problem and a corresponding cylindrically symmetric electrostatic problem. Associated Legendre polynomials appear, as well as ordinary Legendre polynomials. This can be traced to the vector character of the current and vector potential, as opposed to the scalar properties of charge and electrostatic potential.

Another mode of attack on the problem of the planar loop is to employ an expansion in cylindrical waves. Instead of (3.70) as a representation of $|\mathbf{x} - \mathbf{x}'|^{-1}$ we may use the cylindrical form (3.148) or (3.149) or that of Problem 3.14(b). The application of this technique to the circular loop will be left to the problems.

5.6 Magnetic Fields of a Localized Current Distribution, Magnetic Moment

We now consider the properties of a general current distribution which is localized in a small region of space, "small" being relative to the scale of length of interest to the observer. A complete treatment of this problem, in analogy with the electrostatic multipole expansion, can be made using *vector* spherical harmonics.* These are presented in Chapter 16 in connection with multipole radiation. We will be content here with only the lowest order of approximation. Assuming $|\mathbf{x}| \gg |\mathbf{x}'|$, we expand the denominator of (5.32) in powers of \mathbf{x}' measured relative to a suitable origin in the localized current distribution, shown schematically in Fig. 5.6:

$$\frac{1}{|\mathbf{x} - \mathbf{x}'|} = \frac{1}{|\mathbf{x}|} + \frac{\mathbf{x} \cdot \mathbf{x}'}{|\mathbf{x}|^3} + \dots \quad (5.50)$$

Fig. 5.6 Localized current density $\mathbf{J}(\mathbf{x}')$ gives rise to a magnetic induction at the point P with coordinate \mathbf{x} .

* This is not the only way. Scalar potentials can be used. See J. B. Bronzan, *Am. J. Phys.* **39**, 1357 (1971).

Then a given component of the vector potential will have the expansion,

$$A_i(\mathbf{x}) = \frac{1}{c|\mathbf{x}|} \int J_i(\mathbf{x}') d^3x' + \frac{\mathbf{x}}{c|\mathbf{x}|^3} \cdot \int J_i(\mathbf{x}') \mathbf{x}' d^3x' + \dots \quad (5.51)$$

The fact that \mathbf{J} is a localized, divergenceless current distribution permits simplification and transformation of the expansion (5.51). Let $f(\mathbf{x}')$ and $g(\mathbf{x}')$ be well-behaved functions of \mathbf{x}' to be chosen below. Then, if $\mathbf{J}(\mathbf{x}')$ is localized and has zero divergence, we have

$$\int (f\mathbf{J} \cdot \nabla' g + g\mathbf{J} \cdot \nabla' f) d^3x' = 0 \quad (5.52)$$

This can be established by an integration by parts on the second term, followed by expansion of $f\nabla' \cdot (g\mathbf{J})$. With $f=1$ and $g=x'_i$, (5.52) establishes that

$$\int J_i(\mathbf{x}') d^3x' = 0$$

The first term in (5.51), corresponding to the monopole term in the electrostatic expansion, is therefore absent. With $f=x'_i$ and $g=x'_j$ (5.52) yields

$$\int (x'_i J_j + x'_j J_i) d^3x' = 0$$

The integral in the second term of (5.51) can therefore be written

$$\begin{aligned} \mathbf{x} \cdot \int \mathbf{x}' J_i d^3x' &\equiv \sum_j x_j \int x'_j J_i d^3x' \\ &= -\frac{1}{2} \sum_j x_j \int (x'_i J_j - x'_j J_i) d^3x' \\ &= -\frac{1}{2} \sum_{j,k} \epsilon_{ijk} x_j \int (\mathbf{x}' \times \mathbf{J})_k d^3x' \\ &= -\frac{1}{2} \left[\mathbf{x} \times \int (\mathbf{x}' \times \mathbf{J}) d^3x' \right]_i \end{aligned}$$

It is customary to define the *magnetic moment density or magnetization* as

$$\mathcal{M}(\mathbf{x}) = \frac{1}{2c} [\mathbf{x} \times \mathbf{J}(\mathbf{x})] \quad (5.53)$$

and its integral as the *magnetic moment* \mathbf{m} :

$$\mathbf{m} = \frac{1}{2c} \int \mathbf{x}' \times \mathbf{J}(\mathbf{x}') d^3x' \quad (5.54)$$

Then the vector potential from the second term in (5.51) is the magnetic dipole

vector potential,

$$\mathbf{A}(\mathbf{x}) = \frac{\mathbf{m} \times \mathbf{x}}{|\mathbf{x}|^3} \quad (5.55)$$

This is the lowest nonvanishing term in the expansion of \mathbf{A} for a localized steady-state current distribution. The magnetic induction \mathbf{B} outside the localized source can be calculated directly by evaluating the curl of (5.55):

$$\mathbf{B}(\mathbf{x}) = \frac{3\mathbf{n}(\mathbf{n} \cdot \mathbf{m}) - \mathbf{m}}{|\mathbf{x}|^3} \quad (5.56)$$

Here \mathbf{n} is a unit vector in the direction \mathbf{x} . The magnetic induction (5.56) has exactly the form (4.13) of the field of a dipole. This is the generalization of the result found for the circular loop in the last section. Far away from *any* localized current distribution the magnetic induction is that of a magnetic dipole of dipole moment given by (5.54).

If the current is confined to a plane, but otherwise arbitrary, loop, the magnetic moment can be expressed in a simple form. If the current I flows in a closed circuit whose line element is $d\mathbf{l}$, (5.54) becomes

$$\mathbf{m} = \frac{I}{2c} \oint \mathbf{x} \times d\mathbf{l}$$

For a plane loop such as that in Fig. 5.7, the magnetic moment is perpendicular to the plane of the loop. Since $\frac{1}{2} |\mathbf{x} \times d\mathbf{l}| = da$, where da is the triangular element of the area defined by the two ends of $d\mathbf{l}$ and the origin, the loop integral gives the total area of the loop. Hence the magnetic moment has magnitude,

$$|\mathbf{m}| = \frac{I}{c} \times (\text{Area}) \quad (5.57)$$

regardless of the shape of the circuit.

If the current distribution is provided by a number of charged particles with charges q_i and masses M_i in motion with velocities \mathbf{v}_i , the magnetic moment can

Fig. 5.7

be expressed in terms of the orbital angular momentum of the particles. The current density is

$$\mathbf{J} = \sum_i q_i \mathbf{v}_i \delta(\mathbf{x} - \mathbf{x}_i)$$

where \mathbf{x}_i is the position of the i th particle. Then the magnetic moment (5.54) becomes

$$\mathbf{m} = \frac{1}{2c} \sum_i q_i (\mathbf{x}_i \times \mathbf{v}_i)$$

The vector product $(\mathbf{x}_i \times \mathbf{v}_i)$ is proportional to the i th particle's orbital angular momentum, $\mathbf{L}_i = M_i (\mathbf{x}_i \times \mathbf{v}_i)$. Thus the moment becomes

$$\mathbf{m} = \sum_i \frac{q_i}{2M_i c} \mathbf{L}_i \quad (5.58)$$

If all the particles in motion have the same charge to mass ratio ($q_i/M_i = e/M$), the magnetic moment can be written in terms of the *total* orbital angular momentum \mathbf{L} :

$$\mathbf{m} = \frac{e}{2Mc} \sum_i \mathbf{L}_i = \frac{e}{2Mc} \mathbf{L} \quad (5.59)$$

This is the well-known classical connection between angular momentum and magnetic moment which holds for orbital motion even on the atomic scale. But this classical connection fails for the intrinsic moment of electrons and other elementary particles. For electrons, the intrinsic moment is slightly more than twice as large as implied by (5.59), with the spin angular momentum \mathbf{S} replacing \mathbf{L} . Thus we speak of the electron having a g factor of $2(1.00116)$. The departure of the magnetic moment from its classical value has its origins in relativistic and quantum-mechanical effects which we cannot consider here.

Before leaving the topic of the fields of a localized current distribution, we consider the spherical volume integral of the magnetic induction \mathbf{B} . Just as in the electrostatic case discussed at the end of Section 4.1, there are two limits of interest, one in which the sphere of radius R contains all of the current and the other where the current is completely external to the spherical volume. The volume integral of \mathbf{B} is

$$\int_{r < R} \mathbf{B}(\mathbf{x}) d^3x = \int_{r < R} \nabla \times \mathbf{A} d^3x \quad (5.60)$$

The volume integral of the curl of \mathbf{A} can be integrated to give a surface integral. Thus

$$\int_{r < R} \mathbf{B} d^3x = R^2 \int d\Omega \mathbf{n} \times \mathbf{A}$$

where \mathbf{n} is the outwardly directed normal. Substitution of (5.32) for \mathbf{A} and an

interchange of the orders of integration permits this to be written as

$$\int_{r < R} \mathbf{B} d^3x = -\frac{R^2}{c} \int d^3x' \mathbf{J}(\mathbf{x}') \times \int d\Omega \frac{\mathbf{n}}{|\mathbf{x} - \mathbf{x}'|}$$

The angular integral is the same one as occurred in the electrostatic situation. Making use of (4.16') we therefore find for the integral of \mathbf{B} over a spherical volume,

$$\int_{r < R} \mathbf{B} d^3x = \frac{4\pi}{3c} \int \left(\frac{R^2 r_{<}}{r' r_{>}^2} \right) \mathbf{x}' \times \mathbf{J}(\mathbf{x}') d^3x' \quad (5.61)$$

where $(r_{<}, r_{>})$ are the smaller and larger of r' and R . If all the current density is contained within the sphere, $r_{<} = r'$ and $r_{>} = R$. Then

$$\int_{r < R} \mathbf{B} d^3x = \frac{8\pi}{3} \mathbf{m} \quad (5.62)$$

where \mathbf{m} is the total magnetic moment (5.54). For the opposite extreme of the current all external to the sphere, we have, by virtue of (5.14),

$$\int_{r < R} \mathbf{B} d^3x = \frac{4\pi R^3}{3} \mathbf{B}(0) \quad (5.63)$$

The results (5.62) and (5.63) can be compared with their electrostatic counterparts (4.18) and (4.19). The difference between (5.62) and (4.18) is attributable to the difference in the origins of the fields, one from charges and the other from circulating currents. If we wish to include the information of (5.62) in the magnetic dipole field (5.56), we must add a delta function contribution

$$\mathbf{B}(\mathbf{x}) = \frac{3\mathbf{n}(\mathbf{n} \cdot \mathbf{m}) - \mathbf{m}}{|\mathbf{x}|^3} + \frac{8\pi}{3} \mathbf{m} \delta(\mathbf{x}) \quad (5.64)$$

The delta function term enters the expression for the hyperfine structure of atomic s states (see the next section).

5.7 Force and Torque on and Energy of a Localized Current Distribution in an External Magnetic Induction

If a localized distribution of current is placed in an external magnetic induction $\mathbf{B}(\mathbf{x})$, it experiences forces and torques according to Ampère's laws. The general expressions for the total force and torque are given by (5.12) and (5.13). If the external magnetic induction varies slowly over the region of current, a Taylor series expansion can be utilized to find the dominant terms in the force and torque. A component of \mathbf{B} can be expanded around a suitable origin,

$$B_k(\mathbf{x}) = B_k(0) + \mathbf{x} \cdot \nabla B_k(0) + \dots \quad (5.65)$$

Then the i th component of the force (5.12) becomes

$$F_i = \frac{1}{c} \sum_{jk} \epsilon_{ijk} \left[B_k(0) \int J_j(\mathbf{x}') d^3x' + \int J_j(\mathbf{x}') \mathbf{x}' \cdot \nabla B_k(0) d^3x' + \cdots \right] \quad (5.66)$$

Here ϵ_{ijk} is the completely antisymmetric unit tensor ($\epsilon_{ijk} = 1$ for $i = 1, j = 2, k = 3$, and any cyclic permutation, $\epsilon_{ijk} = -1$ for other permutations, and $\epsilon_{ijk} = 0$ for two or more indices equal). The volume integral of \mathbf{J} vanishes for steady currents; the lowest order contribution to the force comes from the second term in (5.66). The result above (5.53) can be used (with $\mathbf{x} \rightarrow \nabla B_k(0)$) to yield

$$F_i = \sum_{jk} \epsilon_{ijk} (\mathbf{m} \times \nabla)_j B_k(\mathbf{x}) \quad (5.67)$$

After differentiation of $B_k(\mathbf{x})$, \mathbf{x} is to be put to zero. This can be written vectorially as

$$\mathbf{F} = (\mathbf{m} \times \nabla) \times \mathbf{B} = \nabla(\mathbf{m} \cdot \mathbf{B}) - \mathbf{m}(\nabla \cdot \mathbf{B}) \quad (5.68)$$

Since $\nabla \cdot \mathbf{B} = 0$ generally, the lowest order force on a localized current distribution in an external magnetic field \mathbf{B} is

$$\mathbf{F} = \nabla(\mathbf{m} \cdot \mathbf{B}) \quad (5.69)$$

This result holds even for time-varying external fields. For steady-state fields, $\nabla \times \mathbf{B} = 0$. Then the force can be expressed alternatively as $\mathbf{F} = (\mathbf{m} \cdot \nabla) \mathbf{B}$.

A localized current distribution in a nonuniform magnetic induction experiences a force proportional to its magnetic moment \mathbf{m} and given by (5.69). One simple application of this result is the time-average force on a charged particle spiraling in a nonuniform magnetic field. As is well known, a charged particle in a *uniform* magnetic induction moves in a circle at right angles to the field and with constant velocity parallel to the field, tracing out a helical path. The circular motion is, on the time average, equivalent to a circular loop of current which will have a magnetic moment given by (5.57). If the field is not uniform but has a small gradient (so that in one turn around the helix the particle does not feel significantly different field strengths), then the motion of the particle can be discussed in terms of the force on the equivalent magnetic moment. Consideration of the signs of the moment and the force shows that charged particles tend to be repelled by regions of high flux density, independent of the sign of their charge. This is the basis of the so-called “magnetic mirrors” discussed in Section 12.6 from another point of view.

The total torque on the localized current distribution is found in a similar way by inserting expansion (5.65) into (5.13). Here the zeroth-order term in the expansion contributes. Keeping only this leading term, we have

$$\mathbf{N} = \frac{1}{c} \int \mathbf{x}' \times [\mathbf{J} \times \mathbf{B}(0)] d^3x' \quad (5.70)$$

Writing out the triple vector product, we get

$$\mathbf{N} = \frac{1}{c} \int [(\mathbf{x}' \cdot \mathbf{B})\mathbf{J} - (\mathbf{x}' \cdot \mathbf{J})\mathbf{B}] d^3x'$$

The first integral has the same form as the one considered in (5.66). Hence we can write down its value immediately. The second integral vanishes for a localized steady-state current distribution, as can be seen from (5.52) with $f=g=r'$. The leading term in the torque is therefore

$$\mathbf{N} = \mathbf{m} \times \mathbf{B}(0) \quad (5.71)$$

This is the familiar expression for the torque on a dipole, discussed in Section 5.1 as one of the ways of defining the magnitude and direction of the magnetic induction.

The potential energy of a permanent magnetic moment (or dipole) in an external magnetic field can be obtained from either the force (5.69) or the torque (5.71). If we interpret the force as the negative gradient of a potential energy U , we find

$$U = -\mathbf{m} \cdot \mathbf{B} \quad (5.72)$$

For a magnetic moment in a uniform field the torque (5.71) can be interpreted as the negative derivative of U with respect to the angle between \mathbf{B} and \mathbf{m} . This well-known result for the potential energy of a dipole shows that the dipole tends to orient itself parallel to the field in the position of lowest potential energy.

We remark in passing that (5.72) is *not* the total energy of the magnetic moment in the external field. In bringing the dipole \mathbf{m} into its final position in the field, work must be done to keep the current \mathbf{J} which produces \mathbf{m} constant. Even though the final situation is a steady-state, there is a transient period initially in which the relevant fields are time dependent. This lies outside our present considerations. Consequently we will leave the discussion of the energy of magnetic fields to Section 6.2, after having treated Faraday's law of induction.

The energy expression (5.72) can be employed in the treatment of magnetic effects on atomic energy levels, as in the Zeeman effect or for the fine and hyperfine structure. The fine structure can be viewed as coming from differences in energy of an electron's intrinsic magnetic moment $\boldsymbol{\mu}_e$ in the magnetic field seen in its rest frame. Fine structure, with the subtle complication of Thomas precession, is discussed briefly in Chapter 11. The hyperfine interaction is that of the magnetic moment $\boldsymbol{\mu}_N$ of the nucleus with the magnetic field produced by the electron. The interaction Hamiltonian is (5.72) with $\mathbf{m} = \boldsymbol{\mu}_N$ and \mathbf{B} equal to the magnetic field of the electron, evaluated at the position of the nucleus ($\mathbf{x}=0$). This field has two parts; one is the dipole field (5.64) and the other is the magnetic field produced by the orbital motion of the electron's charge. The latter is given nonrelativistically by (5.5) and can be expressed as $\mathbf{B}_{\text{orbital}}(0) = e\mathbf{L}/mcr^3$,

where $\mathbf{L} = \mathbf{r} \times m\mathbf{v}$ is the orbital angular momentum of the electron about the nucleus. The hyperfine Hamiltonian is therefore

$$\mathcal{H}_{\text{HFS}} = -\frac{8\pi}{3} \boldsymbol{\mu}_e \cdot \boldsymbol{\mu}_N \delta(\mathbf{r}) + \frac{1}{r^3} \left[\boldsymbol{\mu}_e \cdot \boldsymbol{\mu}_N - 3 \frac{(\mathbf{r} \cdot \boldsymbol{\mu}_e)(\mathbf{r} \cdot \boldsymbol{\mu}_N)}{r^2} - \frac{e}{mc} \mathbf{L} \cdot \boldsymbol{\mu}_N \right] \quad (5.73)$$

The expectation values of this Hamiltonian in the various atomic (and nuclear spin) states yield the hyperfine energy shifts. For spherically symmetric s states the second term in (5.73) gives a zero expectation value. The hyperfine energy comes solely from the first term:

$$\Delta E = -\frac{8\pi}{3} |\psi_e(0)|^2 \langle \boldsymbol{\mu}_e \cdot \boldsymbol{\mu}_N \rangle \quad (5.74)$$

For $l \neq 0$, the hyperfine energy comes entirely from the second term in (5.73) because the wave functions for $l \neq 0$ vanish at the origin. These expressions are due to Fermi who obtained them from the Dirac equation (1930). In applying (5.73) and (5.74) it should be remembered that the charge e is negative and that $\boldsymbol{\mu}_e$ points in the opposite direction to the electron's spin. The energy difference (5.74) between the singlet and triplet states of the $1s$ state of atomic hydrogen is the source of the famous astrophysical 21 cm line.

5.8 Macroscopic Equations, Boundary Conditions on \mathbf{B} and \mathbf{H}

So far we have dealt with the basic laws (5.26) of steady-state magnetic fields as microscopic equations in the sense of the Introduction and Chapter 4. We have assumed that the current density \mathbf{J} was a completely known function of position. In macroscopic problems this is often not true. The atoms in matter have electrons that give rise to effective atomic currents the current density of which is a rapidly fluctuating quantity. Only its average over a macroscopic volume is known or pertinent. Furthermore, the atomic electrons possess intrinsic magnetic moments that cannot be expressed in terms of a classical current density. These moments can give rise to dipole fields that vary appreciably on the atomic scale of dimensions.

The process of averaging the microscopic equations to obtain a macroscopic description of magnetic fields in ponderable media is discussed in detail in Chapter 6. Here, just as in Chapter 4, we give only a sketch of the elementary derivation. The first step is to observe that the averaging of the equation, $\nabla \cdot \mathbf{B}_{\text{micro}} = 0$, leads to the same equation,

$$\nabla \cdot \mathbf{B} = 0 \quad (5.75)$$

for the macroscopic magnetic induction. Thus we can still use the concept of a vector potential $\mathbf{A}(\mathbf{x})$ whose curl gives \mathbf{B} . The large number of molecules or atoms per unit volume, each with its molecular magnetic moment \mathbf{m}_i , give rise to

an average macroscopic *magnetization* or magnetic moment density,

$$\mathbf{M}(\mathbf{x}) = \sum_i N_i \langle \mathbf{m}_i \rangle \quad (5.76)$$

where N_i is the average number per unit volume of molecules of type i and where $\langle \mathbf{m}_i \rangle$ is the average molecular moment in a small volume at the point \mathbf{x} . In addition to the bulk magnetization, we suppose that there is a macroscopic current density $\mathbf{J}(\mathbf{x})$ from the flow of free charge in the medium. Then the vector potential from a small volume ΔV at the point \mathbf{x}' will be

$$\Delta \mathbf{A}(\mathbf{x}) = \frac{\mathbf{J}(\mathbf{x}') \Delta V}{c |\mathbf{x} - \mathbf{x}'|} + \frac{\mathbf{M}(\mathbf{x}') \times (\mathbf{x} - \mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|^3} \Delta V$$

This is the magnetic analog of (4.30). The second term is the dipole vector potential (5.55). Letting ΔV become the macroscopically infinitesimal $d^3 x'$, the total vector potential at \mathbf{x} can be written as the integral over all space,

$$\mathbf{A}(\mathbf{x}) = \frac{1}{c} \int \left[\frac{\mathbf{J}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} + \frac{c \mathbf{M}(\mathbf{x}') \times (\mathbf{x} - \mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|^3} \right] d^3 x' \quad (5.77)$$

The magnetization term can be rewritten as follows:

$$\int \frac{\mathbf{M}(\mathbf{x}') \times (\mathbf{x} - \mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|^3} d^3 x' = \int \mathbf{M}(\mathbf{x}') \times \nabla' \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) d^3 x'$$

Now an integration by parts casts the gradient operator over on to the magnetization and also gives a surface integral. If $\mathbf{M}(\mathbf{x}')$ is well-behaved and localized, the surface integral vanishes. The vector potential (5.77) then becomes

$$\mathbf{A}(\mathbf{x}) = \frac{1}{c} \int \frac{[\mathbf{J}(\mathbf{x}') + c \nabla' \times \mathbf{M}(\mathbf{x}')] }{|\mathbf{x} - \mathbf{x}'|} d^3 x' \quad (5.78)$$

The magnetization is seen to contribute an *effective current density*,

$$\mathbf{J}_M = c \nabla \times \mathbf{M} \quad (5.79)$$

The macroscopic equivalent of the microscopic equation, $\nabla \times \mathbf{B}_{\text{micro}} = 4\pi \mathbf{J}_{\text{micro}}/c$, can be read off from (5.78). If the equations (5.26) have (5.32) as a solution, then (5.78) implies that $\mathbf{J} + \mathbf{J}_M$ plays the role of the current in the macroscopic equivalent, that is:

$$\nabla \times \mathbf{B} = \frac{4\pi}{c} \mathbf{J} + 4\pi \nabla \times \mathbf{M} \quad (5.80)$$

The $\nabla \times \mathbf{M}$ term can be combined with \mathbf{B} to define a new macroscopic field \mathbf{H} , called the *magnetic field*,

$$\mathbf{H} = \mathbf{B} - 4\pi \mathbf{M} \quad (5.81)$$

Then the macroscopic equations, replacing (5.26), are

$$\left. \begin{aligned} \nabla \times \mathbf{H} &= \frac{4\pi}{c} \mathbf{J} \\ \nabla \cdot \mathbf{B} &= 0 \end{aligned} \right\} \quad (5.82)$$

The introduction of \mathbf{H} as a macroscopic field is completely analogous to the introduction of \mathbf{D} for the electrostatic field. The macroscopic equations (5.82) have their electrostatic counterparts,

$$\left. \begin{aligned} \nabla \cdot \mathbf{D} &= 4\pi\rho \\ \nabla \times \mathbf{E} &= 0 \end{aligned} \right\} \quad (5.83)$$

We emphasize that the fundamental fields are \mathbf{E} and \mathbf{B} . They satisfy the homogeneous equations in (5.82) and (5.83). The derived fields, \mathbf{D} and \mathbf{H} , are introduced as a matter of convenience in order to take into account in an average way the contributions to ρ and \mathbf{J} of the atomic charges and currents.

To complete the description of macroscopic magnetostatics, there must be a constitutive relation between \mathbf{H} and \mathbf{B} . As discussed in the Introduction, for isotropic diamagnetic and paramagnetic substances the simple linear relation,

$$\mathbf{B} = \mu \mathbf{H} \quad (5.84)$$

holds, μ being a constant characteristic of the medium and called the *magnetic permeability*. Typically μ differs from unity by only a few parts in 10^5 ($\mu > 1$ for paramagnetic substances and $\mu < 1$ for diamagnetic). For the ferromagnetic substances, (5.84) must be replaced by a nonlinear functional relationship,

$$\mathbf{B} = \mathbf{F}(\mathbf{H}) \quad (5.85)$$

The phenomenon of hysteresis, shown schematically in Fig. 5.8, implies that \mathbf{B} is

Fig. 5.8 Hysteresis loop giving \mathbf{B} in a ferromagnetic material as a function of \mathbf{H} .

not a single-valued function of \mathbf{H} . In fact, the function $\mathbf{F}(\mathbf{H})$ depends on the history of preparation of the material. The incremental permeability of $\mu(\mathbf{H})$ is defined as the derivative of \mathbf{B} with respect to \mathbf{H} , assuming that \mathbf{B} and \mathbf{H} are parallel. For high-permeability substances, $\mu(\mathbf{H})$ can be as high as 10^6 . Most untreated ferromagnetic materials have a linear relation (5.84) between \mathbf{B} and \mathbf{H} for very small fields. Typical values of initial permeability range from 10 to 10^4 .

The complicated relationship between \mathbf{B} and \mathbf{H} in ferromagnetic materials makes analysis of magnetic boundary-value problems inherently more difficult than that of similar electrostatic problems. But the very large values of permeability sometimes allow simplifying assumptions on the boundary conditions.

The boundary conditions for \mathbf{B} and \mathbf{H} at an interface between two media are derived in Section I.5. There it is shown that the normal components of \mathbf{B} and the tangential components of \mathbf{H} on either side of the boundary are related according to

$$(\mathbf{B}_2 - \mathbf{B}_1) \cdot \mathbf{n} = 0 \quad (5.86)$$

$$\mathbf{n} \times (\mathbf{H}_2 - \mathbf{H}_1) = \frac{4\pi}{c} \mathbf{K} \quad (5.87)$$

where \mathbf{n} is a unit normal pointing from region 1 into region 2 and \mathbf{K} is the idealized surface current density. For media satisfying linear relations of the form (5.84) the boundary conditions can be expressed alternatively as

$$\mathbf{B}_2 \cdot \mathbf{n} = \mathbf{B}_1 \cdot \mathbf{n}, \quad \mathbf{B}_2 \times \mathbf{n} = \frac{\mu_2}{\mu_1} \mathbf{B}_1 \times \mathbf{n} \quad (5.88)$$

or

$$\mathbf{H}_2 \cdot \mathbf{n} = \frac{\mu_1}{\mu_2} \mathbf{H}_1 \cdot \mathbf{n}, \quad \mathbf{H}_2 \times \mathbf{n} = \mathbf{H}_1 \times \mathbf{n} \quad (5.89)$$

If $\mu_1 \gg \mu_2$, the normal component of \mathbf{H}_2 is much larger than the normal component of \mathbf{H}_1 , as shown in Fig. 5.9. In the limit $(\mu_1/\mu_2) \rightarrow \infty$, the magnetic field \mathbf{H}_2 is normal to the boundary surface, independent of the direction of \mathbf{H}_1 (barring the exceptional case of \mathbf{H}_1 exactly parallel to the interface). The

Fig. 5.9

boundary condition on \mathbf{H} at the surface of a very high-permeability material is thus the same as for the electric field at the surface of a conductor. We may therefore use electrostatic potential theory for the magnetic field. The surfaces of the high-permeability material are approximately “equipotentials,” and the lines of \mathbf{H} are normal to these equipotentials. This analogy is exploited in many magnet-design problems. The type of field is decided upon, and the pole faces are shaped to be equipotential surfaces.

5.9 Methods of Solving Boundary-Value Problems in Magnetostatics

The basic equations of magnetostatics are

$$\nabla \cdot \mathbf{B} = 0, \quad \nabla \times \mathbf{H} = \frac{4\pi}{c} \mathbf{J} \quad (5.90)$$

with some constitutive relation between \mathbf{B} and \mathbf{H} . The variety of situations that can occur in practice is such that a survey of different techniques for solving boundary-value problems in magnetostatics is worthwhile.

A. Generally Applicable Method of the Vector Potential

Because of the first equation in (5.90) we can always introduce a vector potential $\mathbf{A}(\mathbf{x})$ such that

$$\mathbf{B} = \nabla \times \mathbf{A}$$

If we have an explicit constitutive relation, $\mathbf{H} = \mathbf{H}[\mathbf{B}]$, then the second equation in (5.90) can be written

$$\nabla \times \mathbf{H}[\nabla \times \mathbf{A}] = \frac{4\pi}{c} \mathbf{J}$$

This is, in general, a very complicated differential equation, even if the current distribution is simple, unless \mathbf{H} and \mathbf{B} are simply related. For linear media with $\mathbf{B} = \mu \mathbf{H}$, the equation becomes

$$\nabla \times \left(\frac{1}{\mu} \nabla \times \mathbf{A} \right) = \frac{4\pi}{c} \mathbf{J} \quad (5.91)$$

If μ is constant over a finite region of space, then in that region (5.91) can be written

$$\nabla(\nabla \cdot \mathbf{A}) - \nabla^2 \mathbf{A} = \frac{4\pi\mu}{c} \mathbf{J} \quad (5.92)$$

With the choice of the Coulomb gauge ($\nabla \cdot \mathbf{A} = 0$), this becomes (5.31) with a modified current density, $\mu \mathbf{J}$. The situation closely parallels the treatment of uniform isotropic dielectric media where the effective charge density in the

Poisson equation is ρ/ϵ . Solutions of (5.92) in different linear media must be matched across the boundary surfaces using the boundary conditions (5.88) or (5.89).

B. $\mathbf{J}=0$; Magnetic Scalar Potential

If the current density vanishes in some finite region of space, the second equation in (5.90) becomes $\nabla \times \mathbf{H} = 0$. This implies that we can introduce a magnetic scalar potential Φ_M such that

$$\mathbf{H} = -\nabla\Phi_M \quad (5.93)$$

just as $\mathbf{E} = -\nabla\Phi$ in electrostatics. With an explicit constitutive relation, this time of $\mathbf{B} = \mathbf{B}[\mathbf{H}]$, the $\nabla \cdot \mathbf{B} = 0$ equation can be written

$$\nabla \cdot \mathbf{B}[-\nabla\Phi_M] = 0$$

Again, this is a very complicated differential equation unless the medium is linear, in which case the equation becomes

$$\nabla \cdot (\mu \nabla\Phi_M) = 0 \quad (5.94)$$

If μ is at least *piecewise constant*, in each region the magnetic scalar potential satisfies the Laplace equation,

$$\nabla^2\Phi_M = 0$$

The solutions in the different regions are connected via the boundary conditions (5.89). Note that in this last circumstance of piecewise constancy of μ , we can also write $\mathbf{B} = -\nabla\Psi_M$ with $\nabla^2\Psi_M = 0$. With this alternative scalar potential the boundary conditions (5.88) are appropriate.

The concept of a magnetic scalar potential can be used fruitfully for closed loops of current. It can be shown that Φ_M is proportional to the solid angle subtended by the boundary of the loop at the observation point. See Problem 5.1. Such a potential is evidently multiple-valued.

C. Hard Ferromagnets (\mathbf{M} given and $\mathbf{J} = 0$)

A common practical situation concerns “hard” ferromagnets, having a magnetization that is essentially independent of applied fields for moderate field strengths. Such materials can be treated as if they had a fixed, specified magnetization $\mathbf{M}(\mathbf{x})$.

(a) Scalar Potential

Since $\mathbf{J} = 0$, the magnetic scalar potential Φ_M can be employed. The first equation in (5.90) is written as

$$\nabla \cdot \mathbf{B} = \nabla \cdot (\mathbf{H} + 4\pi\mathbf{M}) = 0$$

Then with (5.93) it becomes a magnetostatic Poisson equation,

$$\nabla^2 \Phi_M = -4\pi \rho_M \quad (5.95)$$

with the *effective magnetic charge density*,

$$\rho_M = -\nabla \cdot \mathbf{M} \quad (5.96)$$

The solution for the potential Φ_M if there are no boundary surfaces is

$$\Phi_M(\mathbf{x}) = - \int \frac{\nabla' \cdot \mathbf{M}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3 x' \quad (5.97)$$

If \mathbf{M} is well-behaved and localized an integration by parts may be performed to yield

$$\Phi_M(\mathbf{x}) = \int \mathbf{M}(\mathbf{x}') \cdot \nabla' \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) d^3 x'$$

Then

$$\nabla' \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) = -\nabla \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right)$$

may be used to give

$$\Phi_M(\mathbf{x}) = -\nabla \cdot \int \frac{\mathbf{M}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3 x' \quad (5.98)$$

In passing we observe that far from the region of nonvanishing magnetization the potential may be approximated by

$$\begin{aligned} \Phi_M(\mathbf{x}) &\approx -\nabla \left(\frac{1}{r} \right) \cdot \int \mathbf{M}(\mathbf{x}') d^3 x' \\ &= \frac{\mathbf{m} \cdot \mathbf{x}}{r^3} \end{aligned}$$

where $\mathbf{m} = \int \mathbf{M} d^3 x$ is the total magnetic moment. This is the scalar potential of a dipole, as can be seen from the electrostatic (4.10). Thus an arbitrary localized distribution of magnetization asymptotically has a dipole field with strength given by the total magnetic moment of the distribution.

While physical distributions of magnetization are mathematically well-behaved and without discontinuities, it is sometimes convenient to idealize the reality and treat $\mathbf{M}(\mathbf{x})$ as if it were discontinuous. Thus, if a “hard” ferromagnet has a volume V and surface S , we specify $\mathbf{M}(\mathbf{x})$ inside V and assume that it falls suddenly to zero at the surface S . Application of the divergence theorem to ρ_M (5.96) in a Gaussian pillbox straddling the surface shows that there is an *effective magnetic surface charge density*,

$$\sigma_M = \mathbf{n} \cdot \mathbf{M} \quad (5.99)$$

where \mathbf{n} is the outwardly directed normal. Then instead of (5.97) the potential

is given by

$$\Phi_M(\mathbf{x}) = - \int_V \frac{\nabla' \cdot \mathbf{M}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3x' + \oint_S \frac{\mathbf{n}' \cdot \mathbf{M}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} da' \quad (5.100)$$

An important special case is that of uniform magnetization throughout the volume V . Then the first term vanishes; only the surface integral over σ_M contributes.

It is important to note that (5.98) is generally applicable, even for the limit of discontinuous distributions of \mathbf{M} , because we can introduce a limiting procedure *after* transforming (5.97) into (5.98) in order to discuss discontinuities in \mathbf{M} . *Never combine the surface integral of σ_M with (5.98)!*

(b) Vector Potential

If we choose to write $\mathbf{B} = \nabla \times \mathbf{A}$ in order to satisfy $\nabla \cdot \mathbf{B} = 0$ automatically, then we write the second equation of (5.90) as

$$\nabla \times \mathbf{H} = \nabla \times (\mathbf{B} - 4\pi \mathbf{M}) = 0$$

This leads to the Poisson equation for \mathbf{A} in the Coulomb gauge,

$$\nabla^2 \mathbf{A} = -\frac{4\pi}{c} \mathbf{J}_M \quad (5.101)$$

where \mathbf{J}_M is the effective magnetic current density (5.79). The solution for the vector potential in the absence of boundary surfaces is

$$\mathbf{A}(\mathbf{x}) = \int \frac{\nabla' \times \mathbf{M}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3x' \quad (5.102)$$

as was already shown in (5.78). An alternative form is given by the magnetization term in (5.77).

If the distribution of magnetization is discontinuous, it is necessary to add a surface integral to (5.102). Starting from (5.77) it can be shown that for \mathbf{M} discontinuously falling to zero at the surface S bounding the volume V , the generalization of (5.102) is

$$\mathbf{A}(\mathbf{x}) = \int_V \frac{\nabla' \times \mathbf{M}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|} d^3x' + \oint_S \frac{\mathbf{M}(\mathbf{x}') \times \mathbf{n}'}{|\mathbf{x} - \mathbf{x}'|} da' \quad (5.103)$$

The effective surface current $c(\mathbf{M} \times \mathbf{n})$ can also be understood by expressing the boundary condition (5.87) for tangential \mathbf{H} in terms of \mathbf{B} and \mathbf{M} . Again, if \mathbf{M} is constant throughout the volume, only the surface integral survives.

5.10 Uniformly Magnetized Sphere

To illustrate the different methods possible for the solution of a boundary-value problem in magnetostatics, we consider in Fig. 5.10 the simple problem of a

$$\mathbf{M} = M_0 \mathbf{e}_3$$

Fig. 5.10

sphere of radius a , with a uniform permanent magnetization \mathbf{M} of magnitude M_0 and parallel to the z axis, embedded in a nonpermeable medium.

The simplest method of solution is that of part C(a) of the previous section, via the magnetic scalar potential in spherical coordinates and a surface magnetic charge density $\sigma_M(\theta)$. With $\mathbf{M} = M_0 \mathbf{e}_3$ and $\sigma_M = \mathbf{n} \cdot \mathbf{M} = M_0 \cos \theta$, the solution (5.100) for the potential is

$$\Phi_M(r, \theta) = M_0 a^2 \int d\Omega' \frac{\cos \theta'}{|\mathbf{x} - \mathbf{x}'|}$$

With the expansion (3.38) or (3.70) for the inverse distance, only the $l=1$ term survives. The potential is

$$\Phi_M(r, \theta) = \frac{4\pi}{3} M_0 a^2 \frac{r_{<}}{r_{>}^2} \cos \theta \quad (5.104)$$

where $(r_{<}, r_{>})$ are the smaller and larger of (r, a) . Inside the sphere, $r_{<} = r$ and $r_{>} = a$. Then $\Phi_M = (4\pi/3) M_0 r \cos \theta = (4\pi/3) M_0 z$. The magnetic field and magnetic induction inside the sphere are therefore

$$\mathbf{H}_{\text{in}} = -\frac{4\pi}{3} \mathbf{M}, \quad \mathbf{B}_{\text{in}} = \frac{8\pi}{3} \mathbf{M} \quad (5.105)$$

We note that \mathbf{B}_{in} is parallel to \mathbf{M} , while \mathbf{H}_{in} is antiparallel. Outside the sphere, $r_{<} = a$ and $r_{>} = r$. The potential is thus

$$\Phi_M = \frac{4\pi}{3} M_0 a^3 \frac{\cos \theta}{r^2} \quad (5.106)$$

This is the potential of a dipole with dipole moment,

$$\mathbf{m} = \frac{4\pi a^3}{3} \mathbf{M} \quad (5.107)$$

For the sphere with uniform magnetization, the fields are not only dipole in character asymptotically, but also close to the sphere. For this special geometry (and this only) there are no higher multipoles.

The lines of \mathbf{B} and \mathbf{H} are shown in Fig. 5.11. The lines of \mathbf{B} are continuous closed paths, but those of \mathbf{H} terminate on the surface because there is an effective surface charge density σ_M .

Brief mention should be made of employing (5.98) instead of (5.100). With $\mathbf{M} = M_0 \mathbf{e}_3$ inside the sphere, (5.98) gives

$$\Phi_M(r, \theta) = -M_0 \frac{\partial}{\partial z} \int_0^a r'^2 dr' \int d\Omega' \frac{1}{|\mathbf{x} - \mathbf{x}'|} \quad (5.108)$$

Now only the $l=0$ term in expansion of the inverse separation survives the angular integration and the integral is a function only of r . With $\partial r / \partial z = \cos \theta$, the potential is

$$\Phi_M(r, \theta) = -4\pi M_0 \cos \theta \frac{\partial}{\partial r} \int_0^a \frac{r'^2 dr'}{r^2}$$

Integration over r' leads directly to the expression (5.104) for Φ_M .

An alternative solution can be accomplished by means of the vector potential and (5.103). Because \mathbf{M} is uniform inside the sphere the volume current density \mathbf{J}_M vanishes, but there is a surface contribution. With $\mathbf{M} = M_0 \mathbf{e}_3$, we have

$$\begin{aligned} \mathbf{M} \times \mathbf{n}' &= M_0 \sin \theta' \mathbf{e}_\phi \\ &= M_0 \sin \theta' (-\sin \phi' \mathbf{e}_1 + \cos \phi' \mathbf{e}_2) \end{aligned}$$

Because of the azimuthal symmetry of the problem we can choose the

Fig. 5.11 Lines of \mathbf{B} and lines of \mathbf{H} for a uniformly magnetized sphere. The lines of \mathbf{B} are closed curves, but the lines of \mathbf{H} originate on the surface of the sphere where the effective surface magnetic "charge," σ_M , resides.

observation point in the x - z plane ($\phi=0$), just as in Section 5.5. Then only the y -component of $\mathbf{M} \times \mathbf{n}'$ survives integration over the azimuth, giving an azimuthal component of the vector potential,

$$A_\phi(\mathbf{x}) = M_0 a^2 \int d\Omega' \frac{\sin \theta' \cos \phi'}{|\mathbf{x} - \mathbf{x}'|} \quad (5.109)$$

where \mathbf{x}' has coordinates (a, θ', ϕ') . The angular factor can be written

$$\sin \theta' \cos \phi' = -\sqrt{\frac{8\pi}{3}} \operatorname{Re}[Y_{1,1}(\theta', \phi')] \quad (5.110)$$

Thus with expansion (3.70) for $|\mathbf{x} - \mathbf{x}'|$ only the $l=1, m=1$ term will survive. Consequently

$$A_\phi(\mathbf{x}) = \frac{4\pi}{3} M_0 a^2 \left(\frac{r_{<}}{r_{>}} \right) \sin \theta \quad (5.111)$$

where $r_{<}$ ($r_{>}$) is the smaller (larger) of r and a . With only a ϕ component of \mathbf{A} , the components of the magnetic induction \mathbf{B} are given by (5.38). Equation (5.111) evidently gives the uniform \mathbf{B} inside and the dipole field outside, as found before.

5.11 Magnetized Sphere in an External Field, Permanent Magnets

In Section 5.10 we discussed the fields of a uniformly magnetized sphere. Because of the linearity of the field equations we can superpose a uniform magnetic induction $\mathbf{B}_0 = \mathbf{H}_0$ throughout all space. Then we have the problem of a uniformly magnetized sphere in an external field. From (5.105) we find that the magnetic induction and field inside the sphere are now

$$\left. \begin{aligned} \mathbf{B}_{\text{in}} &= \mathbf{B}_0 + \frac{8\pi}{3} \mathbf{M} \\ \mathbf{H}_{\text{in}} &= \mathbf{B}_0 - \frac{4\pi}{3} \mathbf{M} \end{aligned} \right\} \quad (5.112)$$

We now imagine that the sphere is not a permanently magnetized object, but rather a paramagnetic or diamagnetic substance of permeability μ . Then the magnetization \mathbf{M} is a result of the application of the external field. To find the magnitude of \mathbf{M} we use (5.84):

$$\mathbf{B}_{\text{in}} = \mu \mathbf{H}_{\text{in}} \quad (5.113)$$

Thus

$$\mathbf{B}_0 + \frac{8\pi}{3} \mathbf{M} = \mu \left(\mathbf{B}_0 - \frac{4\pi}{3} \mathbf{M} \right) \quad (5.114)$$

Fig. 5.12

This gives a magnetization,

$$\mathbf{M} = \frac{3}{4\pi} \left(\frac{\mu - 1}{\mu + 2} \right) \mathbf{B}_0 \quad (5.115)$$

We note that this is completely analogous to the polarization \mathbf{P} of a dielectric sphere in a uniform electric field (4.57).

For a ferromagnetic substance the arguments of the last paragraph fail. Equation (5.115) implies that the magnetization vanishes when the external field vanishes. The existence of permanent magnets contradicts this result. The nonlinear relation (5.85) and the phenomenon of hysteresis allow the creation of permanent magnets. We can solve equations (5.112) for one relation between \mathbf{H}_{in} and \mathbf{B}_{in} by eliminating \mathbf{M} :

$$\mathbf{B}_{\text{in}} + 2\mathbf{H}_{\text{in}} = 3\mathbf{B}_0 \quad (5.116)$$

The hysteresis curve provides the other relation between \mathbf{B}_{in} and \mathbf{H}_{in} , so that specific values can be found for any external field. Equation (5.116) corresponds to a line with slope -2 on the hysteresis diagram with intercept $3\mathbf{B}_0$ on the y axis, as in Fig. 5.12. Suppose, for example, that the external field is increased until the ferromagnetic sphere becomes saturated and then decreased to zero. The internal \mathbf{B} and \mathbf{H} will then be given by the point marked P in Fig. 5.12. The magnetization can be found from (5.112) with $\mathbf{B}_0 = 0$.

The relation (5.116) between \mathbf{B}_{in} and \mathbf{H}_{in} is specific to the sphere. For other geometries other relations pertain. The problem of the ellipsoid can be solved exactly and shows that the slope of the lines (5.116) range from zero for a flat disc to $-\infty$ for a long needle-like object. Thus a larger internal magnetic induction can be obtained with a rod geometry than with spherical or oblate spheroidal shapes.

5.12 Magnetic Shielding, Spherical Shell of Permeable Material in a Uniform Field

Suppose that a certain magnetic induction \mathbf{B}_0 exists in a region of empty space initially. A permeable body is now placed in the region. The lines of magnetic induction are modified. From our remarks at the end of Section 5.8 concerning media of very high permeability we would expect that the field lines would tend to be normal to the surface of the body. Carrying the analogy with conductors further, if the body is hollow, we would expect that the field in the cavity would be smaller than the external field, vanishing in the limit $\mu \rightarrow \infty$. Such a reduction in field is said to be due to the *magnetic shielding* provided by the permeable material. It is of considerable practical importance, since essentially field-free regions are often necessary or desirable for experimental purposes or for the reliable working of electronic devices.

As an example of the phenomenon of magnetic shielding we consider a spherical shell of inner (outer) radius a (b), made of material of permeability μ , and placed in a formerly uniform constant magnetic induction \mathbf{B}_0 , as shown in Fig. 5.13. We wish to find the fields \mathbf{B} and \mathbf{H} everywhere in space, but most particularly in the cavity ($r < a$), as functions of μ . Since there are no currents present, the magnetic field \mathbf{H} is derivable from a scalar potential, $\mathbf{H} = -\nabla\Phi_M$. Furthermore, since $\mathbf{B} = \mu\mathbf{H}$, the divergence equation $\nabla \cdot \mathbf{B} = 0$ becomes $\nabla \cdot \mathbf{H} = 0$ in the various regions. Thus the potential Φ_M satisfies the Laplace equation everywhere. The problem reduces to finding the proper solutions in the different regions to satisfy the boundary conditions (5.89) at $r = a$ and $r = b$.

For $r > b$, the potential must be of the form,

$$\Phi_M = -B_0 r \cos \theta + \sum_{l=0}^{\infty} \frac{\alpha_l}{r^{l+1}} P_l(\cos \theta) \quad (5.117)$$

in order to give the uniform field, $\mathbf{H} = \mathbf{B} = \mathbf{B}_0$, at large distances. For the inner

Fig. 5.13

regions, the potential must be

$$\left. \begin{aligned} a < r < b \quad \Phi_M &= \sum_{l=0}^{\infty} \left(\beta_l r^l + \gamma_l \frac{1}{r^{l+1}} \right) P_l(\cos \theta) \\ r < a \quad \Phi_M &= \sum_{l=0}^{\infty} \delta_l r^l P_l(\cos \theta) \end{aligned} \right\} \quad (5.118)$$

The boundary conditions at $r = a$ and $r = b$ are that H_θ and B_r be continuous. In terms of the potential Φ_M these conditions become

$$\left. \begin{aligned} \frac{\partial \Phi_M}{\partial \theta}(b_+) &= \frac{\partial \Phi_M}{\partial \theta}(b_-) & \frac{\partial \Phi_M}{\partial \theta}(a_+) &= \frac{\partial \Phi_M}{\partial \theta}(a_-) \\ \frac{\partial \Phi_M}{\partial r}(b_+) &= \mu \frac{\partial \Phi_M}{\partial r}(b_-) & \mu \frac{\partial \Phi_M}{\partial r}(a_+) &= \frac{\partial \Phi_M}{\partial r}(a_-) \end{aligned} \right\} \quad (5.119)$$

The notation b_\pm means the limit $r \rightarrow b$ approached from $r \gtrless b$, and similarly for a_\pm . These four conditions, which hold for all angles θ , are sufficient to determine the unknown constants in (5.117) and (5.118). All coefficients with $l \neq 1$ vanish. The $l = 1$ coefficients satisfy the four simultaneous equations

$$\left. \begin{aligned} \alpha_1 - b^3 \beta_1 - \gamma_1 &= b^3 B_0 \\ 2\alpha_1 + \mu b^3 \beta_1 - 2\mu \gamma_1 &= -b^3 B_0 \\ a^3 \beta_1 + \gamma_1 - a^3 \delta_1 &= 0 \\ \mu a^3 \beta_1 - 2\mu \gamma_1 - a^3 \delta_1 &= 0 \end{aligned} \right\} \quad (5.120)$$

The solutions for α_1 and δ_1 are

$$\left. \begin{aligned} \alpha_1 &= \left[\frac{(2\mu+1)(\mu-1)}{(2\mu+1)(\mu+2) - 2\frac{a^3}{b^3}(\mu-1)^2} \right] (b^3 - a^3) B_0 \\ \delta_1 &= - \left[\frac{9\mu}{(2\mu+1)(\mu+2) - 2\frac{a^3}{b^3}(\mu-1)^2} \right] B_0 \end{aligned} \right\} \quad (5.121)$$

The potential outside the spherical shell corresponds to a uniform field \mathbf{B}_0 plus a dipole field (5.41) with dipole moment α_1 oriented parallel to \mathbf{B}_0 . Inside the cavity, there is a uniform magnetic field parallel to \mathbf{B}_0 and equal in magnitude to $-\delta_1$. For $\mu \gg 1$, the dipole moment α_1 and the inner field $-\delta_1$ become

$$\left. \begin{aligned} \alpha_1 &\rightarrow b^3 B_0 \\ -\delta_1 &\rightarrow \frac{9}{2\mu \left(1 - \frac{a^3}{b^3}\right)} B_0 \end{aligned} \right\} \quad (5.122)$$

Fig. 5.14 Shielding effect of a shell of highly permeable material.

We see that the inner field is proportional to μ^{-1} . Consequently a shield made of high-permeability material with $\mu \sim 10^3$ to 10^6 causes a great reduction in the field inside it, even with a relatively thin shell. Figure 5.14 shows the behavior of the lines of \mathbf{B} . The lines tend to pass through the permeable medium if possible.

5.13 Effect of a Circular Hole in a Perfectly Conducting Plane with an Asymptotically Uniform Tangential Magnetic Field on One Side

In Section 3.13 the electrostatic problem of a circular hole in a conducting plane with an asymptotically uniform normal electric field was discussed. Its magnetic counterpart has a uniform tangential magnetic field asymptotically. The two examples are useful in the treatment of small holes in wave guides and resonant cavities (see Section 9.5).

Before sketching the solution of the magnetostatic boundary-value problem, we must discuss what we mean by a perfect conductor. Static magnetic fields penetrate conductors, even excellent ones. The conductor modifies the fields only because of its magnetic properties, not its conductivity, unless of course there is current flow inside. With time-varying fields it is often otherwise. It is shown in Section 8.1 that at the interface between conductor and nonconductor fields with harmonic time dependence penetrate only a distance of the order of $\delta = (c^2/2\pi\omega\sigma)^{1/2}$ into the conductor, where ω is the frequency and σ the

Fig. 5.15

conductivity. For any nonvanishing ω , therefore, the skin depth $\delta \rightarrow 0$ as $\sigma \rightarrow \infty$. Oscillating electric and magnetic fields do not exist inside a perfect conductor. We define magnetostatic problems with perfect conductors as the limit of harmonically varying fields as $\omega \rightarrow 0$, provided that at the same time $\omega\sigma \rightarrow \infty$. Then the magnetic field can exist outside and up to the surface of the conductor, but not inside. The boundary conditions (5.86) and (5.87) show that $\mathbf{B} \cdot \mathbf{n} = 0$, $\mathbf{n} \times \mathbf{H} = 4\pi \mathbf{K}/c$ at the surface. These boundary conditions are the magnetostatic counterparts of the electrostatic boundary conditions, $\mathbf{E}_{\text{tan}} = 0$, $\mathbf{D} \cdot \mathbf{n} = 4\pi\sigma$, at the surface of a conductor, where in this last relation σ is the surface charge density, not the conductivity!

We consider a perfectly conducting plane at $z=0$ with a hole of radius a centered at the origin, as shown in Fig. 5.15. For simplicity we assume that the medium surrounding the plane is uniform, isotropic and linear and that there is a uniform tangential magnetic field \mathbf{H}_0 in the y direction in the region $z > 0$ far from the hole, and zero field asymptotically for $z < 0$. Other possibilities can be obtained by linear superposition. Because there are no currents present except on the surface $z=0$, we can use $\mathbf{H} = -\nabla\Phi_M$, with the magnetic scalar potential $\Phi_M(\mathbf{x})$ satisfying the Laplace equation with suitable mixed boundary conditions. Then we can parallel the solution of Section 3.13.

The potential is written as

$$\Phi_M(x) = \begin{cases} -H_0 y + \Phi^{(1)} & \text{for } z > 0 \\ -\Phi^{(1)} & \text{for } z < 0 \end{cases} \quad (5.123)$$

The reversal of sign for the added potential $\Phi^{(1)}$ below the plane is a consequence of the symmetry properties of the added fields— $H_x^{(1)}$ and $H_y^{(1)}$ are odd in z , while $H_z^{(1)}$ and $\Phi^{(1)}$ are even in z . This can be inferred from (5.14) with the realization that the effective current is only on the surface $z=0$, as is the effective magnetic charge density that determines the scalar potential $\Phi^{(1)}$.

From (3.110) the added potential can be written in cylindrical coordinates as

$$\Phi^{(1)}(\mathbf{x}) = \int_0^\infty dk A(k) e^{-k|z|} J_1(k\rho) \sin \phi \quad (5.124)$$

Only $m=1$ enters because the hole is cylindrically symmetric and the asymptotic field varies as $y=\rho \sin \phi$. From the boundary conditions on normal \mathbf{B} and tangential \mathbf{H} we find that the boundary conditions on the full potential Φ_M are

$$(a) \quad \Phi_M \text{ continuous across } z=0 \quad \text{for } 0 \leq \rho < a$$

$$(b) \quad \frac{\partial \Phi_M}{\partial z} = 0 \text{ at } z=0 \quad \text{for } a < \rho < \infty$$

These requirements imply the dual integral equations,

$$\begin{aligned} \int_0^\infty dk A(k) J_1(k\rho) &= H_0 \rho / 2 & \text{for } 0 \leq \rho < a \\ \int_0^\infty dk k A(k) J_1(k\rho) &= 0 & \text{for } a < \rho < \infty \end{aligned} \quad (5.125)$$

These are closely related to, but different from, the electrostatic set (3.178) or (3.179). The necessary pair here are

$$\begin{aligned} \int_0^\infty dy g(y) J_n(yx) &= x^n, & \text{for } 0 \leq x < 1 \\ \int_0^\infty dy yg(y) J_n(yx) &= 0, & \text{for } 1 < x < \infty \end{aligned} \quad (5.126)$$

with solution,

$$g(y) = \frac{2\Gamma(n+1)}{\sqrt{\pi}\Gamma(n+\frac{1}{2})} j_n(y) = \frac{\Gamma(n+1)}{\Gamma(n+\frac{1}{2})} \left(\frac{2}{y}\right)^{1/2} J_{n+1/2}(y) \quad (5.127)$$

In (5.125) we have $g=2A(k)/H_0 a^2$, $n=1$, $x=\rho/a$, and $y=ka$. Hence

$$A(k) = \frac{2H_0 a^2}{\pi} j_1(ka) \quad (5.128)$$

The added potential is therefore

$$\Phi^{(1)}(\mathbf{x}) = \frac{2H_0 a^2}{\pi} \int_0^\infty dk j_1(ka) e^{-k|z|} J_1(k\rho) \sin \phi \quad (5.129)$$

By methods similar to those of Section 3.13 it can be shown that far from the opening the added potential has the asymptotic form

$$\Phi^{(1)}(\mathbf{x}) \rightarrow \frac{2H_0 a^3}{3\pi} \cdot \frac{y}{r^3} \quad (5.130)$$

This is the potential of a dipole aligned in the y direction, the direction of \mathbf{H}_0 . Because of the signs in (5.123), the circular hole is equivalent at large distances

to a magnetic dipole with moment

$$\mathbf{m} = \pm \frac{2a^3}{3\pi} \mathbf{H}_0 \quad \text{for } z \geq 0 \quad (5.131)$$

where \mathbf{H}_0 is the tangential magnetic field on the $z=0^+$ side of the plane in the absence of the hole. Figure 9.4 shows qualitatively how the magnetic field lines distort to give rise to the dipole field. In the opening itself ($z=0$, $0 \leq \rho < a$) the tangential and normal components of the magnetic field are

$$\begin{aligned} \mathbf{H}_{\text{tan}} &= \frac{1}{2} \mathbf{H}_0 \\ H_z(\rho, 0) &= \frac{2H_0}{\pi} \frac{\rho}{\sqrt{a^2 - \rho^2}} \sin \phi \end{aligned} \quad (5.132)$$

Comparison with the corresponding electrostatic problem in Section 3.13 shows similarities and differences. Roughly speaking, the roles of tangential and normal components of fields have been interchanged. The effective dipoles point in the directions of the asymptotic fields, but the magnetic moment (5.131) is a factor of two larger than the electrostatic moment (3.183) for the same field strengths. For *arbitrarily shaped holes* the far field in the electrostatic case is still that of a dipole normal to the plane, while the magnetic case has its effective dipole in the plane, but now the direction of the magnetic dipole depends on both the field direction and the orientation of the hole (the hole has an anisotropic magnetic susceptibility).

PROBLEMS

5.1 Starting with the differential expression

$$d\mathbf{B} = \frac{I}{c} d\mathbf{l}' \times \frac{(\mathbf{x} - \mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|^3}$$

for the magnetic induction at the point P with coordinate \mathbf{x} produced by an increment of current $I d\mathbf{l}'$ at \mathbf{x}' , show explicitly that for a closed loop carrying a current I the magnetic induction at P is

$$\mathbf{B} = \frac{I}{c} \nabla \Omega$$

where Ω is the solid angle subtended by the loop at the point P . This corresponds to a magnetic scalar potential, $\Phi_M = -I\Omega/c$. The sign convention for the solid angle is that Ω is positive if the point P views the “inner” side of the surface spanning the loop, that is, if a unit normal \mathbf{n} to the surface is defined by the direction of current flow via the right-hand rule, Ω is positive if \mathbf{n} points away from the point P , and negative otherwise. This is the same convention as in Section 1.6 for the electric dipole layer.

5.2 (a) For a solenoid wound with N turns per unit length and carrying a current I , show that the magnetic-flux density on the axis is given for $N \rightarrow \infty$ by

$$B_z = \frac{2\pi NI}{c} (\cos \theta_1 + \cos \theta_2)$$

where the angles are defined in the figure.

(a)

Problem 5.2

(b) For a long solenoid of length L and radius a show that *near the axis and near the center of the solenoid* the magnetic induction is mainly parallel to the axis, but has a small radial component

$$B_\rho \approx \frac{96\pi NI}{c} \left(\frac{a^2 z \rho}{L^4} \right)$$

correct to order a^2/L^2 , and for $z \ll L$, $\rho \ll a$. The coordinate z is measured from the center point of the axis, with the ends of the solenoid at $z = \pm L/2$.

(c) Show that at the end of a long solenoid the magnetic induction near the axis has components

$$B_z \approx \frac{2\pi NI}{c}, \quad B_\rho \approx \pm \frac{\pi NI}{c} \left(\frac{\rho}{a} \right)$$

5.3 A cylindrical conductor of radius a has a hole of radius b bored parallel to, and centered a distance d from, the cylinder axis ($d+b < a$). The current density is uniform throughout the remaining metal of the cylinder and is parallel to the axis. Use Ampère's law and principle of linear superposition to find the magnitude and the direction of the magnetic-flux density in the hole.

5.4 A circular current loop of radius a carrying a current I lies in the x - y plane with its center at the origin.

(a) Show that the only nonvanishing component of the vector potential is

$$A_\phi(\rho, z) = \frac{4Ia}{c} \int_0^\infty dk \cos kz I_1(k\rho_<) K_1(k\rho_>)$$

where $\rho_<$ ($\rho_>$) is the smaller (larger) of a and ρ .

(b) Show that an alternative expression for A_ϕ is

$$A_\phi(\rho, z) = \frac{2\pi Ia}{c} \int_0^\infty dk e^{-k|z|} J_1(ka) J_1(k\rho)$$

(c) Write down integral expressions for the components of magnetic induction, using the expressions of (a) and (b). Evaluate explicitly the components of \mathbf{B} on the z axis by performing the necessary integrations.

5.5 A circular loop of wire carrying a current I is located with its center at the origin of coordinates and the normal to its plane having spherical angles θ_0, ϕ_0 . There is an applied magnetic field, $B_x = B_0(1 + \beta y)$ and $B_y = B_0(1 + \beta x)$.

(a) Calculate the force acting on the loop without making any approximations. Compare your result with the approximate result (5.69). Comment.

(b) Calculate the torque in lowest order. Can you deduce anything about the higher order contributions? Do they vanish for the circular loop? What about for other shapes?

5.6 Two concentric circular loops of radii a, b and currents I, I' , respectively ($b < a$), have an angle α between their planes. Show that the torque on one of the loops is about the line of intersection of the two planes containing the loops and has the magnitude:

$$N = \frac{2\pi^2 II' b^2}{ac^2} \sum_{n=0}^{\infty} \frac{(n+1)}{(2n+1)} \left[\frac{\Gamma(n+\frac{3}{2})}{\Gamma(n+2)\Gamma(\frac{3}{2})} \right]^2 \left(\frac{b}{a} \right)^{2n} P_{2n+1}^1(\cos \alpha)$$

where $P_1^1(\cos \alpha)$ is an associated Legendre polynomial. Determine the sense of the torque for α an acute angle and the currents in the same (opposite) directions.

5.7 A sphere of radius a carries a uniform surface charge distribution σ . The sphere is rotated about a diameter with constant angular velocity ω . Find the vector potential and magnetic-flux density both inside and outside the sphere.

5.8 A long, hollow, right circular cylinder of inner (outer) radius a (b), and of relative permeability μ , is placed in a region of initially uniform magnetic-flux density \mathbf{B}_0 at right angles to the field. Find the flux density at all points in space, and sketch the logarithm of the ratio of the magnitudes of \mathbf{B} on the cylinder axis to \mathbf{B}_0 as a function of $\log_{10} \mu$ for $a^2/b^2 = 0.5, 0.1$. Neglect end effects.

5.9 A current distribution $\mathbf{J}(\mathbf{x})$ exists in a medium of unit permeability adjacent to a semi-infinite slab of material having permeability μ and filling the half-space, $z < 0$.

(a) Show that for $z > 0$ the magnetic induction can be calculated by replacing the medium of permeability μ by an image current distribution, \mathbf{J}^* , with components,

$$\left(\frac{\mu-1}{\mu+1}\right)J_x(x, y, -z), \quad \left(\frac{\mu-1}{\mu+1}\right)J_y(x, y, -z), \quad -\left(\frac{\mu-1}{\mu+1}\right)J_z(x, y, -z)$$

(b) Show that for $z < 0$ the magnetic induction appears to be due to a current distribution $\left(\frac{2\mu}{\mu+1}\right)\mathbf{J}$ in a medium of unit permeability.

5.10 A circular loop of wire having a radius a and carrying a current I is located in vacuum with its center a distance d away from a semi-infinite slab of permeability μ . Find the force acting on the loop when

(a) the plane of the loop is parallel to the face of the slab,

(b) the plane of the loop is perpendicular to the face of the slab.

(c) Determine the limiting form of your answers to (a) and (b) when $d \gg a$. Can you obtain these limiting values in some simple and direct way?

5.11 A magnetically "hard" material is in the shape of a right circular cylinder of length L and radius a . The cylinder has a permanent magnetization M_0 , uniform throughout its volume and parallel to its axis.

(a) Determine the magnetic field \mathbf{H} and magnetic induction \mathbf{B} at all points on the axis of the cylinder, both inside and outside.

(b) Plot the ratios $\mathbf{B}/4\pi M_0$ and $\mathbf{H}/4\pi M_0$ on the axis as functions of z for $L/a = 5$.

5.12 (a) Starting from the force equation (5.12) and the fact that a magnetization \mathbf{M} inside a volume V bounded by a surface S is equivalent to a volume current density $\mathbf{J}_M = c(\nabla \times \mathbf{M})$ and a surface current density $c(\mathbf{M} \times \mathbf{n})$, show that in the absence of macroscopic conduction currents the total magnetic force on the body can be written

$$\mathbf{F} = - \int_V (\nabla \cdot \mathbf{M}) \mathbf{B}_e d^3x + \int_S (\mathbf{M} \cdot \mathbf{n}) \mathbf{B}_e da$$

where \mathbf{B}_e is the applied magnetic induction (not including that of the body in question). The force is now expressed in terms of the effective charge densities ρ_M and σ_M . If the distribution of magnetization is not discontinuous, the surface can be at infinity and the force given by just the volume integral.

(b) A sphere of radius R with uniform magnetization has its center at the origin of coordinates and its direction of magnetization making spherical angles θ_0 , ϕ_0 . If the external magnetic field is the same as in Problem 5.5, use the expression of part (a) to evaluate the components of the force acting on the sphere.

5.13 A magnetostatic field is due entirely to a localized distribution of permanent magnetization.

(a) Show that

$$\int \mathbf{B} \cdot \mathbf{H} d^3x = 0$$

provided the integral is taken over all space.

(b) From the potential energy (5.72) of a dipole in an external field show that for a continuous distribution of permanent magnetization the magnetostatic energy can be written

$$W = \frac{1}{8\pi} \int \mathbf{H} \cdot \mathbf{H} d^3x = -\frac{1}{2} \int \mathbf{M} \cdot \mathbf{H} d^3x$$

apart from an additive constant which is independent of the orientation or position of the various constituent magnetized bodies.

- 5.14 Show that in general a long, straight bar of uniform cross-sectional area A with uniform lengthwise magnetization M , when placed with its flat end against an infinitely permeable flat surface, adheres with a force given approximately by

$$F \approx 2\pi AM^2$$

Relate your discussion to the electrostatic considerations in Section 1.11.

- 5.15 A right circular cylinder of length L and radius a has a uniform lengthwise magnetization M .

(a) Show that, when it is placed with its flat end against an infinitely permeable plane surface, it adheres with a force

$$F = 8\pi aLM^2 \left[\frac{K(k) - E(k)}{k} - \frac{K(k_1) - E(k_1)}{k_1} \right]$$

where

$$k = \frac{2a}{\sqrt{4a^2 + L^2}}, \quad k_1 = \frac{a}{\sqrt{a^2 + L^2}}$$

(b) Find the limiting form for the force if $L \gg a$.

- 5.16 (a) For the perfectly conducting plane of Section 5.13 with the circular hole in it and the asymptotically uniform tangential magnetic field \mathbf{H}_0 on one side, calculate the added tangential magnetic field $\mathbf{H}^{(1)}$ on the side of the plane with \mathbf{H}_0 . Show that its components for $\rho > a$ are

$$H_x^{(1)} = \frac{2H_0a^3}{\pi} \frac{xy}{\rho^4\sqrt{\rho^2 - a^2}}$$

$$H_y^{(1)} = \frac{2H_0a^3}{\pi} \frac{y^2}{\rho^4\sqrt{\rho^2 - a^2}} + \frac{H_0}{\pi} \left[\frac{a}{\rho} \sqrt{1 - \frac{a^2}{\rho^2}} - \sin^{-1} \left(\frac{a}{\rho} \right) \right]$$

(b) Sketch the lines of surface current flow in the neighborhood of the hole on both sides of the plane.

6

Time-Varying Fields, Maxwell Equations, Conservation Laws

In the previous chapters we have dealt with steady-state problems in electricity and in magnetism. Similar mathematical techniques were employed, but electric and magnetic phenomena were treated as independent. The only link between them was the fact that currents which produce magnetic fields are basically electrical in character, being charges in motion. The almost independent nature of electric and magnetic phenomena disappears when we consider time-dependent problems. Time-varying magnetic fields give rise to electric fields and vice-versa. We then must speak of *electromagnetic fields*, rather than electric or magnetic fields. The full import of the interconnection between electric and magnetic fields and their essential sameness becomes clear only within the framework of special relativity (Chapter 11). For the present we content ourselves with examining the basic phenomena and deducing the set of equations known as the *Maxwell equations*, which describe the behavior of electromagnetic fields. Vector and scalar potentials, gauge transformations, and Green functions for the wave equation are next discussed. There follows a proper derivation of the macroscopic equations of electromagnetism. Conservation laws for energy and momentum and transformation properties of electromagnetic quantities are treated, as well as the interesting topic of magnetic monopoles.

In our desire to proceed to other things, we leave out a number of topics which, while of interest in themselves, can be studied elsewhere. Some of these are quasi-stationary fields, circuit theory, apart from the field definitions of impedance and admittance in Section 6.10, inductance calculations, eddy currents, and induction heating. None of these subjects involves new concepts beyond what are developed in this chapter and previous ones. The interested reader will find references at the end of the chapter.

6.1 Faraday's Law of Induction

The first quantitative observations relating time-dependent electric and magnetic fields were made by Faraday (1831) in experiments on the behavior of currents in circuits placed in time-varying magnetic fields. It was observed by Faraday that a transient current is induced in a circuit if (a) the steady current flowing in an adjacent circuit is turned on or off, (b) the adjacent circuit with a steady current flowing is moved relative to the first circuit, (c) a permanent magnet is thrust into or out of the circuit. No current flows unless either the adjacent current changes or there is relative motion. Faraday interpreted the transient current flow as being due to a changing magnetic flux linked by the circuit. The changing flux induces an electric field around the circuit, the line integral of which is called the *electromotive force*, \mathcal{E} . The electromotive force causes a current flow, according to Ohm's law.

We now express Faraday's observations in quantitative mathematical terms. Let the circuit C be bounded by an open surface S with unit normal \mathbf{n} , as in Fig. 6.1. The magnetic induction in the neighborhood of the circuit is \mathbf{B} . The magnetic flux linking the circuit is defined by

$$F = \int_S \mathbf{B} \cdot \mathbf{n} \, da \quad (6.1)$$

The electromotive force around the circuit is

$$\mathcal{E} = \oint_C \mathbf{E}' \cdot d\mathbf{l} \quad (6.2)$$

where \mathbf{E}' is the electric field at the element $d\mathbf{l}$ of the circuit C . Faraday's observations are summed up in the mathematical law,

$$\mathcal{E} = -k \frac{dF}{dt} \quad (6.3)$$

Fig. 6.1

The induced electromotive force around the circuit is proportional to the time rate of change of magnetic flux linking the circuit. The sign is specified by Lenz's law, which states that the induced current (and accompanying magnetic flux) is in such a direction as to oppose the change of flux through the circuit.

The constant of proportionality k depends on the choice of units for the electric and magnetic field quantities. It is not, as might at first be supposed, an independent empirical constant to be determined from experiment. As we will see immediately, once the units and dimensions in Ampère's law have been chosen, the magnitude and dimensions of k follow from the assumption of Galilean invariance for Faraday's law. For Gaussian units, $k = c^{-1}$, where c is the velocity of light.

Before the development of special relativity (and even afterwards, when dealing with relative speeds small compared with the velocity of light), it was understood, although not often explicitly stated, by all physicists that physical laws should be invariant under Galilean transformations. That is, physical phenomena are the same when viewed by two observers moving with a constant velocity \mathbf{v} relative to one another, provided the coordinates in space and time are related by the Galilean transformation, $\mathbf{x}' = \mathbf{x} + \mathbf{v}t$, $t' = t$. In particular, consider Faraday's observations. It is expected and experimentally verified that the same current is induced in a secondary circuit whether it is moved while the primary circuit through which current is flowing is stationary or it is held fixed while the primary circuit is moved in the same relative manner.

Let us now consider Faraday's law for a moving circuit and see the consequences of Galilean invariance. Expressing (6.3) in terms of the integrals over \mathbf{E}' and \mathbf{B} , we have

$$\oint_C \mathbf{E}' \cdot d\mathbf{l} = -k \frac{d}{dt} \int_S \mathbf{B} \cdot \mathbf{n} da \quad (6.4)$$

The induced electromotive force is proportional to the *total* time derivative of the flux—the flux can be changed by changing the magnetic induction or by changing the shape or orientation or position of the circuit. In form (6.4) we have a far-reaching generalization of Faraday's law. The circuit C can be thought of as any closed geometrical path in space, not necessarily coincident with an electric circuit. Then (6.4) becomes a relation between the fields themselves. It is important to note, however, that the electric field, \mathbf{E}' is the electric field at $d\mathbf{l}$ in the coordinate system or medium in which $d\mathbf{l}$ is at rest, since it is that field which causes current to flow if a circuit is actually present.

If the circuit C is moving with a velocity \mathbf{v} in some direction, as shown in Fig. 6.2, the total time derivative in (6.4) must take into account this motion. The flux through the circuit may change because (a) the flux changes with time at a point, or (b) the translation of the circuit changes the location of the boundary. It is easy to show that the result for the total time derivative of flux through the

Fig. 6.2

moving circuit is*

$$\frac{d}{dt} \int_S \mathbf{B} \cdot \mathbf{n} \, da = \int_S \frac{\partial \mathbf{B}}{\partial t} \cdot \mathbf{n} \, da + \oint_C (\mathbf{B} \times \mathbf{v}) \cdot d\mathbf{l} \quad (6.5)$$

Equation (6.4) can now be written in the form,

$$\oint_C [\mathbf{E}' - k(\mathbf{v} \times \mathbf{B})] \cdot d\mathbf{l} = -k \int_S \frac{\partial \mathbf{B}}{\partial t} \cdot \mathbf{n} \, da \quad (6.6)$$

This is an equivalent statement of Faraday's law applied to the moving circuit C . But we can choose to interpret it differently. We can think of the circuit C and surface S as instantaneously at a certain position in space in the laboratory. Applying Faraday's law (6.4) to that fixed circuit, we find

$$\oint_C \mathbf{E} \cdot d\mathbf{l} = -k \int_S \frac{\partial \mathbf{B}}{\partial t} \cdot \mathbf{n} \, da \quad (6.7)$$

where \mathbf{E} is now the electric field in the laboratory. The assumption of Galilean invariance implies that the left-hand sides of (6.6) and (6.7) must be equal. This means that the electric field \mathbf{E}' in the moving coordinate system of the circuit is

$$\mathbf{E}' = \mathbf{E} + k(\mathbf{v} \times \mathbf{B}) \quad (6.8)$$

To determine the constant k we merely observe the significance of \mathbf{E}' . A charged particle (e.g., one of the conduction electrons) essentially at rest in a moving circuit will experience a force $q\mathbf{E}'$. When viewed from the laboratory, the charge represents a current $\mathbf{J} = q\mathbf{v}\delta(\mathbf{x} - \mathbf{x}_0)$. From the magnetic force law (5.7) or (5.12) it is evident that this current experiences a force in agreement with (6.8) provided the constant k is equal to c^{-1} .

* For a general vector field there is an added term, $\int_S (\nabla \cdot \mathbf{B}) \mathbf{v} \cdot \mathbf{n} \, da$, which gives the contribution of the sources of the vector field swept over by the moving circuit. The general result follows most easily from the use of the convective derivative,

$$\frac{d}{dt} = \frac{\partial}{\partial t} + \mathbf{v} \cdot \nabla$$

Thus

$$\frac{d\mathbf{B}}{dt} = \frac{\partial \mathbf{B}}{\partial t} + (\mathbf{v} \cdot \nabla)\mathbf{B} = \frac{\partial \mathbf{B}}{\partial t} + \nabla \times (\mathbf{B} \times \mathbf{v}) + \mathbf{v}(\nabla \cdot \mathbf{B})$$

where \mathbf{v} is treated as a fixed vector in the differentiation. Use of Stokes's theorem on the second term yields (6.5).

Thus we see that, with our choice of units for charge and current, Galilean covariance requires that the present constant k be equal to the constant appearing in the definition of the magnetic field (5.4). Faraday's law (6.4) therefore reads

$$\oint_C \mathbf{E}' \cdot d\mathbf{l} = -\frac{1}{c} \frac{d}{dt} \int_S \mathbf{B} \cdot \mathbf{n} da \quad (6.9)$$

where \mathbf{E}' is the electric field at $d\mathbf{l}$ in its rest frame of coordinates. The time derivative on the right is a *total* time derivative (6.5). As a by-product we have found that the electric field \mathbf{E}' in a coordinate frame moving with a velocity \mathbf{v} relative to the laboratory is

$$\mathbf{E}' = \mathbf{E} + \frac{1}{c} (\mathbf{v} \times \mathbf{B}) \quad (6.10)$$

Because we considered a Galilean transformation, the result (6.10) is an approximation only valid for speeds small compared to the speed of light. (The relativistic expressions are derived in Section 11.10.) Faraday's law is no approximation, however. The Galilean transformation was used merely to evaluate the constant k in (6.3), a task for which it was completely adequate.

Faraday's law (6.9) can be put in differential form by use of Stokes's theorem, provided the circuit is held fixed in the chosen reference frame (in order to have \mathbf{E} and \mathbf{B} defined in the *same* frame). The transformation of the electromotive force integral into a surface integral leads to

$$\int_S \left(\nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} \right) \cdot \mathbf{n} da = 0$$

Since the circuit C and bounding surface S are arbitrary, the integrand must vanish at all points in space.

Thus the differential form of Faraday's law is

$$\nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} = 0 \quad (6.11)$$

We note that this is the time-dependent generalization of the statement, $\nabla \times \mathbf{E} = 0$, for electrostatic fields.

6.2 Energy in the Magnetic Field

In discussing steady-state magnetic fields in Chapter 5 we avoided the question of field energy and energy density. The reason was that the creation of a steady-state configuration of currents and associated magnetic fields involves an initial transient period during which the currents and fields are brought from zero to the final values. For such time-varying fields there are induced electromotive forces which cause the sources of current to do work. Since the energy in the field is by definition the total work done to establish it, we must consider these contributions.

Suppose for a moment that we have only a single circuit with a constant current I flowing in it. If the flux through the circuit changes, an electromotive force \mathcal{E} is induced around it. In order to keep the current constant, the sources of current must do work. To determine the rate we note that the time rate of change of energy of a particle with velocity \mathbf{v} acted on by a force \mathbf{F} is $dE/dt = \mathbf{v} \cdot \mathbf{F}$. With a changing flux the added field \mathbf{E}' on each conduction electron of charge q and drift velocity \mathbf{v} gives rise to a change in energy per unit time of $q\mathbf{v} \cdot \mathbf{E}'$ per electron. Summing over all the electrons in the circuit, we find that the sources do work to maintain the current at the rate,

$$\frac{dW}{dt} = -I\mathcal{E} = \frac{1}{c} I \frac{dF}{dt}$$

the negative sign following from Lenz's law. This is in addition to ohmic losses in the circuit which are not to be included in the magnetic-energy content. Thus, if the flux change through a circuit carrying a current I is δF , the work done by the sources is

$$\delta W = \frac{1}{c} I \delta F$$

Now we consider the problem of the work done in establishing a general steady-state distribution of currents and fields. We can imagine that the build-up process occurs at an infinitesimal rate so that $\nabla \cdot \mathbf{J} = 0$ holds to any desired degree of accuracy. Then the current distribution can be broken up into a network of elementary current loops, the typical one of which is an elemental tube of current of cross-sectional area $\Delta\sigma$ following a closed path C and spanned by a surface S with normal \mathbf{n} , as shown in Fig. 6.3.

We can express the increment of work done against the induced emf in terms of the change in magnetic induction through the loop:

$$\Delta(\delta W) = \frac{J \Delta\sigma}{c} \int_S \mathbf{n} \cdot \delta \mathbf{B} da$$

where the extra Δ comes from the fact that we are considering only one

Fig. 6.3 Distribution of current density broken up into elemental current loops.

elemental circuit. If we express \mathbf{B} in terms of the vector potential \mathbf{A} , then we have

$$\Delta(\delta W) = \frac{J \Delta \sigma}{c} \int_s (\nabla \times \delta \mathbf{A}) \cdot \mathbf{n} da$$

With application of Stokes's theorem this can be written

$$\Delta(\delta W) = \frac{J \Delta \sigma}{c} \oint_C \delta \mathbf{A} \cdot d\mathbf{l}$$

But $J \Delta \sigma d\mathbf{l}$ is equal to $\mathbf{J} d^3x$, by definition, since $d\mathbf{l}$ is parallel to \mathbf{J} . Evidently the sum over all such elemental loops will be the volume integral. Hence the total increment of work done by the external sources due to a change $\delta \mathbf{A}(\mathbf{x})$ in the vector potential is

$$\delta W = \frac{1}{c} \int \delta \mathbf{A} \cdot \mathbf{J} d^3x \quad (6.12)$$

An expression involving the magnetic fields rather than \mathbf{J} and $\delta \mathbf{A}$ can be obtained by using Ampère's law:

$$\nabla \times \mathbf{H} = \frac{4\pi}{c} \mathbf{J}$$

Then

$$\delta W = \frac{1}{4\pi} \int \delta \mathbf{A} \cdot (\nabla \times \mathbf{H}) d^3x \quad (6.13)$$

The vector identity,

$$\nabla \cdot (\mathbf{P} \times \mathbf{Q}) = \mathbf{Q} \cdot (\nabla \times \mathbf{P}) - \mathbf{P} \cdot (\nabla \times \mathbf{Q})$$

can be used to transform (6.13):

$$\delta W = \frac{1}{4\pi} \int [\mathbf{H} \cdot (\nabla \times \delta \mathbf{A}) + \nabla \cdot (\mathbf{H} \times \delta \mathbf{A})] d^3x \quad (6.14)$$

If the field distribution is assumed to be localized, the second integral vanishes. With the definition of \mathbf{B} in terms of \mathbf{A} , the energy increment can be written:

$$\delta W = \frac{1}{4\pi} \int \mathbf{H} \cdot \delta \mathbf{B} d^3x \quad (6.15)$$

This relation is the magnetic equivalent of the electrostatic equation (4.86). In its present form it is applicable to all magnetic media, including ferromagnetic substances. If we assume that the medium is para- or diamagnetic, so that a linear relation exists between \mathbf{H} and \mathbf{B} , then

$$\mathbf{H} \cdot \delta \mathbf{B} = \frac{1}{2} \delta(\mathbf{H} \cdot \mathbf{B})$$

If we now bring the fields up from zero to their final values, the total magnetic

energy will be

$$W = \frac{1}{8\pi} \int \mathbf{H} \cdot \mathbf{B} d^3x \quad (6.16)$$

This is the magnetic analog of (4.89).

The magnetic equivalent of (4.83) where the electrostatic energy is expressed in terms of charge density and potential, can be obtained from (6.12) by assuming a linear relation between \mathbf{J} and \mathbf{A} . Then we find the magnetic energy to be

$$W = \frac{1}{2c} \int \mathbf{J} \cdot \mathbf{A} d^3x \quad (6.17)$$

The magnetic problem of the change in energy when an object of permeability μ_1 is placed in a magnetic field whose current sources are fixed can be treated in close analogy with the electrostatic discussion of Section 4.7. The role of \mathbf{E} is taken by \mathbf{B} , that of \mathbf{D} by \mathbf{H} . The original medium has permeability μ_0 and existing magnetic induction \mathbf{B}_0 . After the object is in place the fields are \mathbf{B} and \mathbf{H} . It is left as an exercise for the reader to verify that for fixed sources of the field the change in energy is

$$W = \frac{1}{8\pi} \int_{V_1} (\mathbf{B} \cdot \mathbf{H}_0 - \mathbf{H} \cdot \mathbf{B}_0) d^3x \quad (6.18)$$

where the integration is over the volume of the object. This can be written in the alternative forms:

$$W = \frac{1}{8\pi} \int_{V_1} (\mu_1 - \mu_0) \mathbf{H} \cdot \mathbf{H}_0 d^3x = \frac{1}{8\pi} \int_{V_1} \left(\frac{1}{\mu_0} - \frac{1}{\mu_1} \right) \mathbf{B} \cdot \mathbf{B}_0 d^3x \quad (6.19)$$

Both μ_1 and μ_0 can be functions of position, but they are assumed independent of field strength.

If the object is in otherwise free space ($\mu_0 = 1$), the change in energy can be expressed in terms of the magnetization as

$$W = \frac{1}{2} \int_{V_1} \mathbf{M} \cdot \mathbf{B}_0 d^3x \quad (6.20)$$

It should be noted that (6.20) is equivalent to the electrostatic result (4.93), except for sign. This sign change arises because the energy W consists of the total energy change occurring when the permeable body is introduced in the field, including the work done by the sources against the induced electromotive forces. In this respect the magnetic problem with fixed currents is analogous to the electrostatic problem with fixed potentials on the surfaces which determine the fields. By an analysis equivalent to that at the end of Section 4.7 we can show that for a small displacement the work done against the induced emf's is twice as large as, and of the opposite sign to, the potential-energy change of the body.

Thus, to find the force acting on the body, we consider a generalized displacement ξ and calculate the *positive* derivative of W with respect to the displacement:

$$F_{\xi} = \left(\frac{\partial W}{\partial \xi} \right)_J \quad (6.21)$$

The subscript J implies fixed source currents.

The difference between (6.20) and the potential energy (5.72) for a permanent magnetic moment in an external field (apart from the factor $\frac{1}{2}$, which is traced to the linear relation assumed between \mathbf{M} and \mathbf{B}) comes from the fact that (6.20) is the total energy required to produce the configuration, whereas (5.72) includes only the work done in establishing the permanent magnetic moment in the field, not the work done in creating the magnetic moment and keeping it permanent.

6.3 Maxwell's Displacement Current, Maxwell Equations

The basic laws of electricity and magnetism which we have discussed so far can be summarized in differential form by these four (not yet Maxwell) equations:

Coulomb's law:	$\nabla \cdot \mathbf{D} = 4\pi\rho$	} (6.22)
Ampère's law ($\nabla \cdot \mathbf{J} = 0$):	$\nabla \times \mathbf{H} = \frac{4\pi}{c} \mathbf{J}$	
Faraday's law:	$\nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} = 0$	
Absence of free magnetic poles:	$\nabla \cdot \mathbf{B} = 0$	

These equations are written in macroscopic form and in Gaussian units. Let us recall that all but Faraday's law were derived from steady-state observations. Consequently, from a logical point of view there is no *a priori* reason to expect that the static equations hold unchanged for time-dependent fields. In fact, the equations in set (6.22) are inconsistent as they stand.

It required the genius of J. C. Maxwell, spurred on by Faraday's observations, to see the inconsistency in equations (6.22) and to modify them into a consistent set which implied new physical phenomena, at that time unknown but subsequently verified in all details by experiment. For this brilliant stroke in 1865, the modified set of equations is justly known as the *Maxwell equations*.

The faulty equation is Ampère's law. It was derived for steady-state current phenomena with $\nabla \cdot \mathbf{J} = 0$. This requirement on the divergence of \mathbf{J} is contained right in Ampère's law, as can be seen by taking the divergence of both sides:

$$\frac{4\pi}{c} \nabla \cdot \mathbf{J} = \nabla \cdot (\nabla \times \mathbf{H}) \equiv 0 \quad (6.23)$$

While $\nabla \cdot \mathbf{J} = 0$ is valid for steady-state problems, the complete relation is given by the continuity equation for charge and current:

$$\nabla \cdot \mathbf{J} + \frac{\partial \rho}{\partial t} = 0 \quad (6.24)$$

What Maxwell saw was that the continuity equation could be converted into a vanishing divergence by using Coulomb's law (6.22). Thus

$$\nabla \cdot \mathbf{J} + \frac{\partial \rho}{\partial t} = \nabla \cdot \left(\mathbf{J} + \frac{1}{4\pi} \frac{\partial \mathbf{D}}{\partial t} \right) = 0 \quad (6.25)$$

Then Maxwell replaced \mathbf{J} in Ampère's law by its generalization,

$$\mathbf{J} \rightarrow \mathbf{J} + \frac{1}{4\pi} \frac{\partial \mathbf{D}}{\partial t} \quad (6.26)$$

for time-dependent fields. Thus Ampère's law became

$$\nabla \times \mathbf{H} = \frac{4\pi}{c} \mathbf{J} + \frac{1}{c} \frac{\partial \mathbf{D}}{\partial t} \quad (6.27)$$

still the same, experimentally verified, law for steady-state phenomena, but now mathematically consistent with the continuity equation (6.24) for time-dependent fields. Maxwell called the added term in (6.26) the *displacement current*. This necessary addition to Ampère's law is of crucial importance for rapidly fluctuating fields. Without it there would be no electromagnetic radiation, and the greatest part of the remainder of this book would have to be omitted. It was Maxwell's prediction that light was an electromagnetic wave phenomenon, and that electromagnetic waves of all frequencies could be produced, which drew the attention of all physicists and stimulated so much theoretical and experimental research into electromagnetism during the last part of the nineteenth century.

The set of four equations,

$$\left. \begin{aligned} \nabla \cdot \mathbf{D} &= 4\pi\rho & \nabla \times \mathbf{H} &= \frac{4\pi}{c} \mathbf{J} + \frac{1}{c} \frac{\partial \mathbf{D}}{\partial t} \\ \nabla \cdot \mathbf{B} &= 0 & \nabla \times \mathbf{E} &+ \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} = 0 \end{aligned} \right\} \quad (6.28)$$

known as the *Maxwell equations*, forms the basis of all classical electromagnetic phenomena. When combined with the Lorentz force equation and Newton's second law of motion, these equations provide a complete description of the classical dynamics of interacting charged particles and electromagnetic fields (see Section 6.8 and Chapters 10, 12, and 17). The range of validity of the Maxwell equations is discussed in the Introduction, as are questions of boundary conditions for the normal and tangential components of fields at interfaces between different media. Constitutive relations connecting \mathbf{E} and \mathbf{B} with \mathbf{D} and

H have been touched on in the Introduction and treated for static phenomena in Chapters 4 and 5. More will be said later in this chapter and in Chapter 7.

The units employed in writing the Maxwell equations (6.28) are those of the previous chapters, namely, Gaussian. For the reader more at home in other units, such as MKSA, Table 2 of the Appendix summarizes essential equations in the commoner systems. Table 3 of the Appendix allows the conversion of any equation from Gaussian to MKSA units, while Table 4 gives the corresponding conversions for given amounts of any variable.

6.4 Vector and Scalar Potentials

The Maxwell equations consist of a set of coupled first-order partial differential equations relating the various components of electric and magnetic fields. They can be solved as they stand in simple situations. But it is often convenient to introduce potentials, obtaining a smaller number of second-order equations, while satisfying some of the Maxwell equations identically. We are already familiar with this concept in electrostatics and magnetostatics, where we used the scalar potential Φ and the vector potential \mathbf{A} .

Since $\nabla \cdot \mathbf{B} = 0$ still holds, we can define \mathbf{B} in terms of a vector potential:

$$\mathbf{B} = \nabla \times \mathbf{A} \quad (6.29)$$

Then the other homogeneous equation in (6.28), Faraday's law, can be written

$$\nabla \times \left(\mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{A}}{\partial t} \right) = 0 \quad (6.30)$$

This means that the quantity with vanishing curl in (6.30) can be written as the gradient of some scalar function, namely, a scalar potential Φ :

$$\text{or} \quad \left. \begin{aligned} \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{A}}{\partial t} &= -\nabla \Phi \\ \mathbf{E} &= -\nabla \Phi - \frac{1}{c} \frac{\partial \mathbf{A}}{\partial t} \end{aligned} \right\} \quad (6.31)$$

The definition of \mathbf{B} and \mathbf{E} in terms of the potentials \mathbf{A} and Φ according to (6.29) and (6.31) satisfies identically the two homogeneous Maxwell equations. The dynamic behavior of \mathbf{A} and Φ will be determined by the two inhomogeneous equations in (6.28).

At this stage it is convenient to restrict our considerations to the vacuum form of the Maxwell equations. Then the inhomogeneous equations in (6.28) can

be written in terms of the potentials as

$$\nabla^2 \Phi + \frac{1}{c} \frac{\partial}{\partial t} (\nabla \cdot \mathbf{A}) = -4\pi\rho \quad (6.32)$$

$$\nabla^2 \mathbf{A} - \frac{1}{c^2} \frac{\partial^2 \mathbf{A}}{\partial t^2} - \nabla \left(\nabla \cdot \mathbf{A} + \frac{1}{c} \frac{\partial \Phi}{\partial t} \right) = -\frac{4\pi}{c} \mathbf{J} \quad (6.33)$$

We have now reduced the set of four Maxwell equations to two equations. But they are still coupled equations. The uncoupling can be accomplished by exploiting the arbitrariness involved in the definition of the potentials. Since \mathbf{B} is defined through (6.29) in terms of \mathbf{A} , the vector potential is arbitrary to the extent that the gradient of some scalar function Λ can be added. Thus \mathbf{B} is left unchanged by the transformation,

$$\mathbf{A} \rightarrow \mathbf{A}' = \mathbf{A} + \nabla \Lambda \quad (6.34)$$

In order that the electric field (6.31) be unchanged as well, the scalar potential must be simultaneously transformed,

$$\Phi \rightarrow \Phi' = \Phi - \frac{1}{c} \frac{\partial \Lambda}{\partial t} \quad (6.35)$$

The freedom implied by (6.34) and (6.35) means that we can choose a set of potentials (\mathbf{A}, Φ) such that

$$\nabla \cdot \mathbf{A} + \frac{1}{c} \frac{\partial \Phi}{\partial t} = 0 \quad (6.36)$$

This will uncouple the pair of equations (6.32) and (6.33) and leave two inhomogeneous wave equations, one for Φ and one for \mathbf{A} :

$$\nabla^2 \Phi - \frac{1}{c^2} \frac{\partial^2 \Phi}{\partial t^2} = -4\pi\rho \quad (6.37)$$

$$\nabla^2 \mathbf{A} - \frac{1}{c^2} \frac{\partial^2 \mathbf{A}}{\partial t^2} = -\frac{4\pi}{c} \mathbf{J} \quad (6.38)$$

Equations (6.37) and (6.38), plus (6.36), form a set of equations equivalent in all respects to the Maxwell equations.

6.5 Gauge Transformations, Lorentz Gauge, Coulomb Gauge

The transformation (6.34) and (6.35) is called a *gauge transformation*, and the invariance of the fields under such transformations is called *gauge invariance*. The relation (6.36) between \mathbf{A} and Φ is called the *Lorentz condition*. To see that potentials can always be found to satisfy the Lorentz condition, suppose that the potentials \mathbf{A}, Φ which satisfy (6.32) and (6.33) do not satisfy (6.36). Then let us

make a gauge transformation to potentials \mathbf{A}' , Φ' and demand that \mathbf{A}' , Φ' satisfy the Lorentz condition:

$$\nabla \cdot \mathbf{A}' + \frac{1}{c} \frac{\partial \Phi'}{\partial t} = 0 = \nabla \cdot \mathbf{A} + \frac{1}{c} \frac{\partial \Phi}{\partial t} + \nabla^2 \Lambda - \frac{1}{c^2} \frac{\partial^2 \Lambda}{\partial t^2} \quad (6.39)$$

Thus, provided a gauge function Λ can be found to satisfy

$$\nabla^2 \Lambda - \frac{1}{c^2} \frac{\partial^2 \Lambda}{\partial t^2} = - \left(\nabla \cdot \mathbf{A} + \frac{1}{c} \frac{\partial \Phi}{\partial t} \right) \quad (6.40)$$

the new potentials \mathbf{A}' , Φ' will satisfy the Lorentz condition and the wave equations (6.37) and (6.38).

Even for potentials which satisfy the Lorentz condition (6.36) there is arbitrariness. Evidently the *restricted gauge transformation*,

$$\left. \begin{aligned} \mathbf{A} &\rightarrow \mathbf{A} + \nabla \Lambda \\ \Phi &\rightarrow \Phi - \frac{1}{c} \frac{\partial \Lambda}{\partial t} \end{aligned} \right\} \quad (6.41)$$

where

$$\nabla^2 \Lambda - \frac{1}{c^2} \frac{\partial^2 \Lambda}{\partial t^2} = 0 \quad (6.42)$$

preserves the Lorentz condition, provided \mathbf{A} , Φ satisfy it initially. All potentials in this restricted class are said to belong to the *Lorentz gauge*. The Lorentz gauge is commonly used, first because it leads to the wave equations (6.37) and (6.38) which treat Φ and \mathbf{A} on equivalent footings, and second because it is a concept which is independent of the coordinate system chosen and so fits naturally into the considerations of special relativity (see Section 11.9).

Another useful gauge for the potentials is the so-called *Coulomb, radiation or transverse gauge*. This is the gauge in which

$$\nabla \cdot \mathbf{A} = 0 \quad (6.43)$$

From (6.32) we see that the scalar potential satisfies the Poisson equation,

$$\nabla^2 \Phi = -4\pi\rho \quad (6.44)$$

with solution,

$$\Phi(\mathbf{x}, t) = \int \frac{\rho(\mathbf{x}', t)}{|\mathbf{x} - \mathbf{x}'|} d^3x' \quad (6.45)$$

The scalar potential is just the *instantaneous* Coulomb potential due to the charge density $\rho(\mathbf{x}, t)$. This is the origin of the name "Coulomb gauge."

The vector potential satisfies the inhomogeneous wave equation,

$$\nabla^2 \mathbf{A} - \frac{1}{c^2} \frac{\partial^2 \mathbf{A}}{\partial t^2} = -\frac{4\pi}{c} \mathbf{J} + \frac{1}{c} \nabla \frac{\partial \Phi}{\partial t} \quad (6.46)$$

The term involving the scalar potential can, in principle, be calculated from

(6.45). Since it involves the gradient operator it is a term that is *irrotational*, that is, has vanishing curl. This suggests that it may cancel a corresponding piece of the current density. The current density (or any vector field) can be written as the sum of two terms,

$$\mathbf{J} = \mathbf{J}_l + \mathbf{J}_t \quad (6.47)$$

where \mathbf{J}_l is called the *longitudinal* or *irrotational* current and has $\nabla \times \mathbf{J}_l = 0$, while \mathbf{J}_t is called the *transverse* or *solenoidal* current and has $\nabla \cdot \mathbf{J}_t = 0$. Starting from the vector identity,

$$\nabla \times (\nabla \times \mathbf{J}) = \nabla (\nabla \cdot \mathbf{J}) - \nabla^2 \mathbf{J} \quad (6.48)$$

together with $\nabla^2(1/|\mathbf{x} - \mathbf{x}'|) = -4\pi\delta(\mathbf{x} - \mathbf{x}')$, it can be shown that \mathbf{J}_l and \mathbf{J}_t can be constructed explicitly from \mathbf{J} as follows:

$$\mathbf{J}_l = -\frac{1}{4\pi} \nabla \int \frac{\nabla' \cdot \mathbf{J}}{|\mathbf{x} - \mathbf{x}'|} d^3x' \quad (6.49)$$

$$\mathbf{J}_t = \frac{1}{4\pi} \nabla \times \nabla \times \int \frac{\mathbf{J}}{|\mathbf{x} - \mathbf{x}'|} d^3x' \quad (6.50)$$

With the help of the continuity equation and (6.45) it is seen that

$$\nabla \frac{\partial \Phi}{\partial t} = 4\pi \mathbf{J}_l \quad (6.51)$$

Therefore the source for the wave equation for \mathbf{A} can be expressed entirely in terms of the *transverse* current (6.50):

$$\nabla^2 \mathbf{A} - \frac{1}{c^2} \frac{\partial^2 \mathbf{A}}{\partial t^2} = -\frac{4\pi}{c} \mathbf{J}_t \quad (6.52)$$

This, of course, is the origin of the name “transverse gauge.” The name “radiation gauge” stems from the fact that transverse radiation fields are given by the vector potential alone, the instantaneous Coulomb potential contributing only to the near fields. This gauge is particularly useful in quantum electrodynamics. A quantum-mechanical description of photons necessitates quantization of only the vector potential.

The Coulomb or transverse gauge is often used when no sources are present. Then $\Phi = 0$, and \mathbf{A} satisfies the homogeneous wave equation. The fields are given by

$$\left. \begin{aligned} \mathbf{E} &= -\frac{1}{c} \frac{\partial \mathbf{A}}{\partial t} \\ \mathbf{B} &= \nabla \times \mathbf{A} \end{aligned} \right\} \quad (6.53)$$

In passing we note a peculiarity of the Coulomb gauge. It is well known that electromagnetic disturbances propagate with finite speed. Yet (6.45) indicates

that the scalar potential “propagates” instantaneously everywhere in space. The vector potential, on the other hand, satisfies the wave equation (6.52), with its implied finite speed of propagation c . At first glance it is puzzling to see how this obviously unphysical behavior is avoided. A preliminary remark is that it is the fields, not the potentials, that concern us. A further observation is that the *transverse* current (6.50) extends over all space, even if \mathbf{J} is localized.*

6.6 Green Functions for the Wave Equation

The wave equations (6.37), (6.38), and (6.52) all have the basic structure,

$$\nabla^2 \Psi - \frac{1}{c^2} \frac{\partial^2 \Psi}{\partial t^2} = -4\pi f(\mathbf{x}, t) \quad (6.54)$$

where $f(\mathbf{x}, t)$ is a known source distribution. The factor c is the velocity of propagation in the medium, assumed here to be without dispersion.

To solve (6.54) it is useful to find a Green function, just as in electrostatics. We consider the simple situation of no boundary surfaces and proceed to remove the explicit time dependence by introducing a Fourier transform with respect to frequency. We suppose that $\Psi(\mathbf{x}, t)$ and $f(\mathbf{x}, t)$ have the Fourier integral representations,

$$\left. \begin{aligned} \Psi(\mathbf{x}, t) &= \frac{1}{2\pi} \int_{-\infty}^{\infty} \Psi(\mathbf{x}, \omega) e^{-i\omega t} d\omega \\ f(\mathbf{x}, t) &= \frac{1}{2\pi} \int_{-\infty}^{\infty} f(\mathbf{x}, \omega) e^{-i\omega t} d\omega \end{aligned} \right\} \quad (6.55)$$

with the inverse transformations,

$$\left. \begin{aligned} \Psi(\mathbf{x}, \omega) &= \int_{-\infty}^{\infty} \Psi(\mathbf{x}, t) e^{i\omega t} dt \\ f(\mathbf{x}, \omega) &= \int_{-\infty}^{\infty} f(\mathbf{x}, t) e^{i\omega t} dt \end{aligned} \right\} \quad (6.56)$$

When the representations (6.55) are inserted into (6.54) it is found that the Fourier transform $\Psi(\mathbf{x}, \omega)$ satisfies the *inhomogeneous Helmholtz wave equation*

$$(\nabla^2 + k^2) \Psi(\mathbf{x}, \omega) = -4\pi f(\mathbf{x}, \omega) \quad (6.57)$$

for each value of ω . Here $k = \omega/c$ is the wave number associated with frequency ω . In this form, the restriction of no dispersion is unnecessary. A priori, any connection between k and ω is allowed, although causality imposes some restrictions (see Section 7.10).

* See O. L. Brill and B. Goodman, *Am. J. Phys.* **35**, 832 (1967) for a detailed discussion of causality in the Coulomb gauge. See also Problem 6.19.

Equation (6.57) is an elliptic partial differential equation similar to the Poisson equation to which it reduces for $k=0$. The Green function $G(\mathbf{x}, \mathbf{x}')$ appropriate to (6.57) satisfies the inhomogeneous equation,

$$(\nabla^2 + k^2)G_k(\mathbf{x}, \mathbf{x}') = -4\pi\delta(\mathbf{x} - \mathbf{x}') \quad (6.58)$$

If there are no boundary surfaces, the Green function can only depend on $\mathbf{R} = \mathbf{x} - \mathbf{x}'$, and must in fact be spherically symmetric, that is, depend only on $R = |\mathbf{R}|$. From the form of the Laplacian operator in spherical coordinates [see (3.1)], it is evident that $G_k(R)$ satisfies

$$\frac{1}{R} \frac{d^2}{dR^2} (RG_k) + k^2 G_k = -4\pi\delta(\mathbf{R}) \quad (6.59)$$

Everywhere except $R=0$, $RG_k(R)$ satisfies the homogeneous equation

$$\frac{d^2}{dR^2} (RG_k) + k^2 (RG_k) = 0$$

with solution,

$$RG_k(R) = Ae^{ikR} + Be^{-ikR}$$

Furthermore, the delta function in (6.59) only has influence at $R \rightarrow 0$. In that limit the equation reduces to the Poisson equation since $kR \ll 1$. We therefore know from electrostatics that the correct normalization is

$$\lim_{kR \rightarrow 0} G_k(R) = \frac{1}{R} \quad (6.60)$$

The general solution for the Green function is thus

$$G_k(R) = AG_k^{(+)}(R) + BG_k^{(-)}(R) \quad (6.61)$$

where

$$G_k^{(\pm)}(R) = \frac{e^{\pm ikR}}{R} \quad (6.62)$$

with $A+B=1$. With the convention of (6.55) for the time dependence, the first term in (6.61) represents a diverging spherical wave propagating from the origin, while the second represents a converging spherical wave.

The choice of A and B in (6.61) depends on the *boundary conditions in time* that specify the physical problem. It is intuitively obvious that, if a source is quiescent until some time $t=0$ and then begins to function, the appropriate Green function is the first term in (6.61), corresponding to waves radiated outwards from the source after it begins to work. Such a description is certainly correct and also convenient, but is not unique or necessary. By suitable specification of the wave amplitude at boundary times it is possible to employ the second term in (6.61), not the first, to describe the action of the source.

To understand the different time behaviors associated with $G_k^{(+)}$ and $G_k^{(-)}$ we

need to construct the corresponding time-dependent Green functions that satisfy

$$\left(\nabla_x^2 - \frac{1}{c^2} \frac{\partial^2}{\partial t^2}\right) G^{(\pm)}(\mathbf{x}, t; \mathbf{x}', t') = -4\pi \delta(\mathbf{x} - \mathbf{x}') \delta(t - t') \quad (6.63)$$

Using (6.56) we see that the source term for (6.57) is

$$-4\pi \delta(\mathbf{x} - \mathbf{x}') e^{i\omega t'}$$

The solutions are therefore $G_k^{(\pm)}(R) e^{i\omega t'}$. From (6.55) the time-dependent Green functions are

$$G^{(\pm)}(R, \tau) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{e^{\pm i k R}}{R} \cdot e^{-i\omega \tau} d\omega \quad (6.64)$$

where $\tau = t - t'$ is the relative time appearing in (6.63). The infinite-space Green function is thus a function of only the relative distance R and the relative time τ between source and observation point. For a nondispersive medium where $k = \omega/c$, the integral in (6.64) is a delta function. The Green functions are

$$G^{(\pm)}(R, \tau) = \frac{1}{R} \delta\left(\tau \mp \frac{R}{c}\right) \quad (6.65)$$

or, more explicitly,

$$G^{(\pm)}(\mathbf{x}, t; \mathbf{x}', t') = \frac{\delta\left(t' - \left[t \mp \frac{|\mathbf{x} - \mathbf{x}'|}{c}\right]\right)}{|\mathbf{x} - \mathbf{x}'|} \quad (6.66)$$

The Green function $G^{(+)}$ is called the *retarded Green function* because it exhibits the causal behavior associated with a wave disturbance. The argument of the delta function shows that an effect observed at the point \mathbf{x} at time t is caused by the action of a source a distance R away at an earlier or retarded time, $t' = t - R/c$. The time difference R/c is just the time of propagation of the disturbance from one point to the other. Similarly, $G^{(-)}$ is called the *advanced Green function*.

Particular integrals of the inhomogeneous wave equation (6.54) are

$$\Psi^{(\pm)}(\mathbf{x}, t) = \iint G^{(\pm)}(\mathbf{x}, t; \mathbf{x}', t') f(\mathbf{x}', t') d^3x' dt'$$

To either of these may be added solutions of the homogeneous equation in order to specify a definite physical problem. We consider a source distribution $f(\mathbf{x}', t')$ that is localized in time and space. It is different from zero only for a finite interval of time around $t' = 0$. Two limiting situations are envisioned. In the first it is assumed that at time $t \rightarrow -\infty$ there exists a wave $\Psi_{\text{in}}(\mathbf{x}, t)$ that satisfies the homogeneous wave equation. This wave propagates in time and space; the source turns on and generates waves of its own. The complete solution for this

situation at all times is evidently

$$\Psi(\mathbf{x}, t) = \Psi_{\text{in}}(\mathbf{x}, t) + \iint G^{(+)}(\mathbf{x}, t; \mathbf{x}', t') f(\mathbf{x}', t') d^3x' dt' \quad (6.67)$$

The presence of $G^{(+)}$ guarantees that at remotely early times, t , before the source has been activated, there is no contribution from the integral. Only the specified wave Ψ_{in} exists. The second situation is that at remotely late times ($t \rightarrow +\infty$) the wave is given as $\Psi_{\text{out}}(\mathbf{x}, t)$, a known solution of the homogeneous wave equation. Then the complete solution for all times is

$$\Psi(\mathbf{x}, t) = \Psi_{\text{out}}(\mathbf{x}, t) + \iint G^{(-)}(\mathbf{x}, t; \mathbf{x}', t') f(\mathbf{x}', t') d^3x' dt' \quad (6.68)$$

Now the advanced Green function assures that no signal from the source shall exist explicitly after the source shuts off (all such signals are by assumption included in Ψ_{out}).

The commonest physical situation is described by (6.67) with $\Psi_{\text{in}}=0$. It is sometimes written with the Green function (6.66) inserted explicitly:

$$\Psi(\mathbf{x}, t) = \int \frac{[f(\mathbf{x}', t')]_{\text{ret}}}{|\mathbf{x} - \mathbf{x}'|} d^3x' \quad (6.69)$$

The square bracket $[]_{\text{ret}}$ means that the time t' is to be evaluated at the retarded time, $t' = t - |\mathbf{x} - \mathbf{x}'|/c$.

The initial or final value problem at *finite* times has been extensively studied in one, two, and three dimensions. The reader may refer to *Morse and Feshbach*, pp. 843–847, and also to the more mathematical treatment of *Hadamard*.

6.7 Derivation of the Equations of Macroscopic Electromagnetism

The discussion of electromagnetism in the preceding chapters has been based on the *macroscopic* Maxwell equations,

$$\begin{aligned} \nabla \cdot \mathbf{B} &= 0 & \nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} &= 0 \\ \nabla \cdot \mathbf{D} &= 4\pi\rho & \nabla \times \mathbf{H} - \frac{1}{c} \frac{\partial \mathbf{D}}{\partial t} &= \frac{4\pi}{c} \mathbf{J} \end{aligned} \quad (6.70)$$

where \mathbf{E} and \mathbf{B} are the macroscopic electric and magnetic field quantities, \mathbf{D} and \mathbf{H} are corresponding derived fields, related to \mathbf{E} and \mathbf{B} through the polarization \mathbf{P} and the magnetization \mathbf{M} of the material medium by

$$\mathbf{D} = \mathbf{E} + 4\pi\mathbf{P}, \quad \mathbf{H} = \mathbf{B} - 4\pi\mathbf{M} \quad (6.71)$$

Similarly, ρ and \mathbf{J} are the macroscopic (free) charge density and current density, respectively. Although these equations are familiar and totally acceptable, we

have yet to present a serious derivation of them from a microscopic starting point. This deficiency is remedied in the present section. The derivation remains within a classical framework even though atoms must be described quantum mechanically. The excuse for this apparent inadequacy is that the quantum-mechanical discussion closely parallels the classical one, with quantum-mechanical expectation values replacing the classical quantities in the formulas given below. The reader can examine the statistical mechanical treatments in the literature cited at the end of the chapter.

We consider a microscopic world made up of electrons and nuclei. For dimensions large compared to 10^{-12} cm, the nuclei can be treated as point systems, as can the electrons. We assume that the equations governing electromagnetic phenomena for these point charges are the *microscopic* Maxwell equations,

$$\begin{aligned}\nabla \cdot \mathbf{b} &= 0, & \nabla \times \mathbf{e} + \frac{1}{c} \frac{\partial \mathbf{b}}{\partial t} &= 0 \\ \nabla \cdot \mathbf{e} &= 4\pi\eta, & \nabla \times \mathbf{b} - \frac{1}{c} \frac{\partial \mathbf{e}}{\partial t} &= \frac{4\pi}{c} \mathbf{j}\end{aligned}\tag{6.72}$$

where \mathbf{e} and \mathbf{b} are the microscopic electric and magnetic fields and η and \mathbf{j} are the microscopic charge and current densities. There are no corresponding fields \mathbf{d} and \mathbf{h} because all of the charges are included in η and \mathbf{j} . A macroscopic amount of matter at rest contains of the order of $10^{23 \pm 5}$ electrons and nuclei, all in incessant motion because of thermal agitation, zero point vibration, or orbital motion. The microscopic electromagnetic fields produced by these charges vary extremely rapidly in space and in time. The spatial variations occur over distances of the order of 10^{-8} cm or less, and the temporal fluctuations occur with periods ranging from 10^{-13} sec for nuclear vibrations to 10^{-17} sec for electronic orbital motion. Macroscopic measuring devices generally average over intervals in space and time much larger than these. All the microscopic fluctuations are therefore averaged out, giving relatively smooth and slowly varying macroscopic quantities, such as appear in the macroscopic Maxwell equations.

The question of what type of averaging is appropriate must be examined with some care. At first glance one might think that averages over both space and time are necessary. But this is not true. Only a spatial averaging is necessary. (Parenthetically, we note that a time averaging alone would certainly not be sufficient, as can be seen by considering an ionic crystal whose ions have small zero point vibrations around well defined and separated lattice sites.) To delimit the domain where we expect a macroscopic description of electromagnetic phenomena to work, we observe that the reflection and refraction of visible light is adequately described by the Maxwell equations with a continuous dielectric constant, whereas X-ray diffraction clearly exposes the atomistic nature of matter. It is plausible therefore to take the length $L_0 = 10^{-6}$ cm = 10^2 Å as the

absolute lower limit to the macroscopic domain. The period of oscillation associated with light of this wavelength is $L_0/c \approx 3 \times 10^{-17}$ sec. In a volume of $L_0^3 = 10^{-18} \text{ cm}^3$ there are, in ordinary matter, still of the order of 10^6 nuclei and electrons. Thus in any region of macroscopic interest with $L \gg L_0$ there are so many nuclei and electrons that the fluctuations will be completely washed out by a spatial averaging. On the other hand, because the time scale associated with L is actually in the range of atomic and molecular motions, a time-averaging would not be appropriate. There is, nevertheless, no evidence after the spatial averaging of the microscopic time fluctuations of the medium. This is so because, in the absence of special preparation and the establishment of ordering over macroscopic distances, the time variations of the microscopic fields are uncorrelated over distances of order L . All that survive are the frequency components corresponding to oscillators driven at the external, applied frequencies.

The spatial average of a function $F(\mathbf{x}, t)$ with respect to a test function $f(\mathbf{x})$ is defined as

$$\langle F(\mathbf{x}, t) \rangle = \int d^3x' f(\mathbf{x}') F(\mathbf{x} - \mathbf{x}', t) \quad (6.73)$$

where $f(\mathbf{x})$ is real, nonzero in some neighborhood of $\mathbf{x} = 0$, and normalized to unity over all space. It is simplest, though not necessary, to imagine $f(\mathbf{x})$ to be nonnegative. In order to preserve without bias directional characteristics of averaged physical properties, we make $f(\mathbf{x})$ isotropic in space. Two examples are

$$f(\mathbf{x}) = \begin{cases} \frac{3}{4\pi R^3}, & r < R \\ 0, & r > R \end{cases}$$

$$f(\mathbf{x}) = (\pi R^2)^{-3/2} e^{-r^2/R^2}$$

The first example, a spherical averaging volume of radius R , is a common one in the literature. It has the advantage of conceptual simplicity, but the disadvantage of an abrupt discontinuity at $r = R$. This leads to a fine-scale jitter on the averaged quantities as a single molecule or group of molecules moves in or out of the averaging volume. A smooth test function, exemplified by the Gaussian, eliminates such difficulties provided its scale is large compared to atomic dimensions. Fortunately, the test function $f(\mathbf{x})$ does not need to be specified in detail; all that are needed are general continuity and smoothness properties that permit a rapidly converging Taylor series expansion of $f(\mathbf{x})$ over distances of atomic dimensions, as indicated schematically in Fig. 6.4. This is a great virtue.*

Since space and time derivatives enter the Maxwell equations, we must consider these operations with respect to averaging according to (6.73).

* We are here following the development of G. Russakoff, *Am. J. Physics* **38**, 1188 (1970).

Fig. 6.4 Schematic diagram of test function $f(\mathbf{x})$ used in the spatial averaging procedure. The extent L of the plateau region, and also the extent ΔL of the region where f falls to zero, are both large compared to the molecular dimension a .

Evidently, we have

$$\frac{\partial}{\partial x_i} \langle F(\mathbf{x}, t) \rangle = \int d^3 x' f(\mathbf{x}') \frac{\partial F}{\partial x_i}(\mathbf{x} - \mathbf{x}', t) = \left\langle \frac{\partial F}{\partial x_i} \right\rangle$$

(6.74)

and

$$\frac{\partial}{\partial t} \langle F(\mathbf{x}, t) \rangle = \left\langle \frac{\partial F}{\partial t} \right\rangle$$

The operations of space and time differentiation thus commute with the averaging operation.

We can now consider the averaging of the microscopic Maxwell equations (6.72). The *macroscopic* electric and magnetic field quantities \mathbf{E} and \mathbf{B} are defined as the averages of the microscopic fields \mathbf{e} and \mathbf{b} :

$$\begin{aligned} \mathbf{E}(\mathbf{x}, t) &= \langle \mathbf{e}(\mathbf{x}, t) \rangle \\ \mathbf{B}(\mathbf{x}, t) &= \langle \mathbf{b}(\mathbf{x}, t) \rangle \end{aligned} \quad (6.75)$$

Then the averages of the two homogeneous equations in (6.72) become the corresponding macroscopic equations,

$$\begin{aligned} \langle \nabla \cdot \mathbf{b} \rangle &= 0 \rightarrow \nabla \cdot \mathbf{B} = 0 \\ \left\langle \nabla \times \mathbf{e} + \frac{1}{c} \frac{\partial \mathbf{b}}{\partial t} \right\rangle &= 0 \rightarrow \nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} = 0 \end{aligned} \quad (6.76)$$

The averaged inhomogeneous equations from (6.72) become

$$\begin{aligned} \nabla \cdot \mathbf{E} &= 4\pi \langle \eta(\mathbf{x}, t) \rangle \\ \nabla \times \mathbf{B} - \frac{1}{c} \frac{\partial \mathbf{E}}{\partial t} &= \frac{4\pi}{c} \langle \mathbf{j}(\mathbf{x}, t) \rangle \end{aligned} \quad (6.77)$$

Comparison with the inhomogeneous pair of macroscopic equations in (6.70) indicates the already known fact that the derived fields \mathbf{D} and \mathbf{H} are introduced

by the extraction from $\langle \eta \rangle$ and $\langle \mathbf{j} \rangle$ of certain contributions that can be identified with the bulk properties of the medium. The examination of $\langle \eta \rangle$ and $\langle \mathbf{j} \rangle$ is therefore the next task.

We consider a medium made up of molecules composed of nuclei and electrons and, in addition, “free” charges that are not localized around any particular molecule. The microscopic charge density can be written as

$$\eta(\mathbf{x}, t) = \sum_j q_j \delta[\mathbf{x} - \mathbf{x}_j(t)] \quad (6.78)$$

where $\mathbf{x}_j(t)$ is the position of the point charge q_j . To distinguish the bound charges from the free ones, we decompose η as

$$\eta = \eta_{\text{free}} + \eta_{\text{bound}} \quad (6.79)$$

and write

$$\begin{aligned} \eta_{\text{free}} &= \sum_{j(\text{free})} q_j \delta(\mathbf{x} - \mathbf{x}_j) \\ \eta_{\text{bound}} &= \sum_n \eta_n(\mathbf{x}, t) \\ &\quad (\text{molecules}) \end{aligned}$$

where η_n is the charge density of the n th molecule,

$$\eta_n(\mathbf{x}, t) = \sum_{j(n)} q_j \delta(\mathbf{x} - \mathbf{x}_j) \quad (6.80)$$

In these and subsequent equations we suppress the explicit time dependence since the averaging is done at one instant of time. We proceed by averaging the charge density of the n th molecule and then summing up the contributions of all molecules. It is appropriate to express the coordinates of the charges in the n th molecule with respect to an origin at rest in the molecule. Let the coordinate of that fixed point in the molecule (usually chosen as the center of mass) be $\mathbf{x}_n(t)$, and the coordinate of the j th charge in the molecule be $\mathbf{x}_{jn}(t)$ relative to that origin, as indicated in Fig. 6.5. The average of the charge density of the n th molecule is

$$\begin{aligned} \langle \eta_n(\mathbf{x}, t) \rangle &= \int d^3x' f(\mathbf{x}') \eta_n(\mathbf{x} - \mathbf{x}', t) \\ &= \sum_{j(n)} q_j \int d^3x' f(\mathbf{x}') \delta(\mathbf{x} - \mathbf{x}' - \mathbf{x}_{jn} - \mathbf{x}_n) \\ &= \sum_{j(n)} q_j f(\mathbf{x} - \mathbf{x}_n - \mathbf{x}_{jn}) \end{aligned} \quad (6.81)$$

Since \mathbf{x}_{jn} is of order atomic dimensions, the terms in the sum have arguments differing only slightly from $(\mathbf{x} - \mathbf{x}_n)$ on the scale over which $f(\mathbf{x})$ changes appreciably. It is therefore appropriate to make a Taylor series expansion around $(\mathbf{x} - \mathbf{x}_n)$ for each term. This gives

$$\langle \eta_n(\mathbf{x}, t) \rangle = \sum_{j(n)} q_j \left[f(\mathbf{x} - \mathbf{x}_n) - \mathbf{x}_{jn} \cdot \nabla f(\mathbf{x} - \mathbf{x}_n) + \frac{1}{2} \sum_{\alpha\beta} (\mathbf{x}_{jn})_\alpha (\mathbf{x}_{jn})_\beta \frac{\partial^2}{\partial x_\alpha \partial x_\beta} f(\mathbf{x} - \mathbf{x}_n) + \cdots \right]$$

Fig. 6.5 Coordinates for the n th molecule. The origin O' is fixed in the molecule (usually it is chosen at the center of mass). The j th charge has coordinate \mathbf{x}_{jn} relative to O' , while the molecule is located relative to the fixed (laboratory) axes by the coordinate \mathbf{x}_n .

The various sums over the charges in the molecule are just *molecular multipole moments*:

$$\text{Molecular charge} \quad q_n = \sum_{j(n)} q_j \quad (6.82)$$

$$\text{Molecular dipole moment} \quad \mathbf{p}_n = \sum_{j(n)} q_j \mathbf{x}_{jn} \quad (6.83)$$

$$\text{Molecular quadrupole moment} \quad (Q'_n)_{\alpha\beta} = 3 \sum_{j(n)} q_j (\mathbf{x}_{jn})_\alpha (\mathbf{x}_{jn})_\beta \quad (6.84)$$

In terms of these multipole moments the averaged charge density of the n th molecule is

$$\langle \eta_n(\mathbf{x}, t) \rangle = q_n f(\mathbf{x} - \mathbf{x}_n) - \mathbf{p}_n \cdot \nabla f(\mathbf{x} - \mathbf{x}_n) + \frac{1}{6} \sum_{\alpha\beta} (Q'_n)_{\alpha\beta} \frac{\partial^2 f(\mathbf{x} - \mathbf{x}_n)}{\partial x_\alpha \partial x_\beta} + \dots \quad (6.85)$$

If we attempt to view this equation as the direct result of the definition (6.73) of the spatial averaging, we see that the first term can be thought of as the averaging of a point charge density at $\mathbf{x} = \mathbf{x}_n$, the second as the divergence of the

average of a point dipole density at $\mathbf{x}=\mathbf{x}_n$, and so on. Explicitly,

$$\langle \eta_n(\mathbf{x}, t) \rangle = \langle q_n \delta(\mathbf{x} - \mathbf{x}_n) \rangle - \nabla \cdot \langle \mathbf{p}_n \delta(\mathbf{x} - \mathbf{x}_n) \rangle + \frac{1}{6} \sum_{\alpha\beta} \frac{\partial^2}{\partial x_\alpha \partial x_\beta} \langle (Q'_n)_{\alpha\beta} \delta(\mathbf{x} - \mathbf{x}_n) \rangle + \dots \quad (6.86)$$

We thus find that, as far as the result of the averaging process is concerned, we can view the molecule as a collection of point multipoles located at one fixed point in the molecule. The detailed extent of the molecular charge distribution is important at the microscopic level, of course, but is replaced in its effect by a sum of multipoles for macroscopic phenomena.

The total microscopic charge density (6.79) consists of the free and bound charges. Summing up over all the molecules (which may be of different species) and combining with the free charges, we find the *averaged* microscopic charge density to be

$$\langle \eta(\mathbf{x}, t) \rangle = \rho(\mathbf{x}, t) - \nabla \cdot \mathbf{P}(\mathbf{x}, t) + \sum_{\alpha\beta} \frac{\partial^2}{\partial x_\alpha \partial x_\beta} Q'_{\alpha\beta}(\mathbf{x}, t) + \dots \quad (6.87)$$

where ρ is the *macroscopic charge density*,

$$\rho(\mathbf{x}, t) = \left\langle \sum_{j(\text{free})} q_j \delta(\mathbf{x} - \mathbf{x}_j) + \sum_{n \text{ (molecules)}} q_n \delta(\mathbf{x} - \mathbf{x}_n) \right\rangle \quad (6.88)$$

\mathbf{P} is the *macroscopic polarization*,

$$\mathbf{P}(\mathbf{x}, t) = \left\langle \sum_{n \text{ (molecules)}} \mathbf{p}_n \delta(\mathbf{x} - \mathbf{x}_n) \right\rangle \quad (6.89)$$

and $Q'_{\alpha\beta}$ is the *macroscopic quadrupole density*,

$$Q'_{\alpha\beta}(\mathbf{x}, t) = \frac{1}{6} \left\langle \sum_{n \text{ (molecules)}} (Q'_n)_{\alpha\beta} \delta(\mathbf{x} - \mathbf{x}_n) \right\rangle \quad (6.90)$$

When (6.87) is inserted in the first equation of (6.77), it gives

$$\sum_{\alpha} \frac{\partial}{\partial x_\alpha} \left[E_\alpha + 4\pi P_\alpha - 4\pi \sum_{\beta} \frac{\partial}{\partial x_\beta} Q'_{\alpha\beta} + \dots \right] = 4\pi \rho \quad (6.91)$$

From (6.70) this means that the *macroscopic displacement vector* \mathbf{D} is defined to have components,

$$D_\alpha = E_\alpha + 4\pi P_\alpha - 4\pi \sum_{\beta} \frac{\partial Q'_{\alpha\beta}}{\partial x_\beta} + \dots \quad (6.92)$$

The first two terms are the familiar result (6.71). The third and higher terms are present in principle, but are almost invariably negligible.

To complete the discussion we must consider $\langle \mathbf{j} \rangle$. Because of its vector nature and the presence of velocities the derivation is considerably more complicated

than the previous treatment of $\langle \eta \rangle$, even though involving no new principles. We present only the results, leaving the gory details to a problem for those readers who enjoy such challenges. We begin with the microscopic current density,

$$\mathbf{j}(\mathbf{x}, t) = \sum_j q_j \mathbf{v}_j \delta(\mathbf{x} - \mathbf{x}_j(t)) \quad (6.93)$$

where $\mathbf{v}_j = d\mathbf{x}_j/dt$ is the velocity of the j th charge. Again the sum is divided into one over the free charges and one over the molecules. The current density of the n th molecule can be averaged just as in (6.81) to give

$$\langle \mathbf{j}_n(\mathbf{x}, t) \rangle = \sum_{j(n)} q_j (\mathbf{v}_{jn} + \mathbf{v}_n) f(\mathbf{x} - \mathbf{x}_n - \mathbf{x}_{jn}) \quad (6.94)$$

Here we have assumed nonrelativistic motion by writing the velocity of the j th charge as the sum of an internal relative velocity \mathbf{v}_{jn} and the velocity $\mathbf{v}_n = d\mathbf{x}_n/dt$ of the origin O' in the molecule. From this point on the development entails Taylor series expansions and vector manipulations. A portion of the current involves the *molecular magnetic moment*,

$$\mathbf{m}_n = \sum_{j(n)} \frac{q_j}{2c} (\mathbf{x}_{jn} \times \mathbf{v}_{jn}) \quad (6.95)$$

The final result for a component of the *averaged* microscopic current density is

$$\begin{aligned} \langle j_\alpha(\mathbf{x}, t) \rangle = & J_\alpha(\mathbf{x}, t) + \frac{1}{4\pi} \frac{\partial}{\partial t} [D_\alpha(\mathbf{x}, t) - E_\alpha(\mathbf{x}, t)] + c \sum_{\beta\gamma} \epsilon_{\alpha\beta\gamma} \frac{\partial}{\partial x_\beta} M_\gamma(\mathbf{x}, t) \\ & + \sum_\beta \frac{\partial}{\partial x_\beta} \left\langle \sum_n [(\mathbf{p}_n)_\alpha (\mathbf{v}_n)_\beta - (\mathbf{p}_n)_\beta (\mathbf{v}_n)_\alpha] \delta(\mathbf{x} - \mathbf{x}_n) \right\rangle \\ & - \frac{1}{6} \sum_{\beta\gamma} \frac{\partial^2}{\partial x_\beta \partial x_\gamma} \left\langle \sum_n [(Q'_n)_{\alpha\beta} (\mathbf{v}_n)_\gamma - (Q'_n)_{\gamma\beta} (\mathbf{v}_n)_\alpha] \delta(\mathbf{x} - \mathbf{x}_n) \right\rangle + \dots \end{aligned} \quad (6.96)$$

The so-far undefined quantities in this rather formidable equation are the *macroscopic current density*,

$$\mathbf{J}(\mathbf{x}, t) = \left\langle \sum_{j(\text{free})} q_j \mathbf{v}_j \delta(\mathbf{x} - \mathbf{x}_j) + \sum_n q_n \mathbf{v}_n \delta(\mathbf{x} - \mathbf{x}_n) \right\rangle \quad (6.97)$$

and the *macroscopic magnetization*,

$$\mathbf{M}(\mathbf{x}, t) = \left\langle \sum_n \mathbf{m}_n \delta(\mathbf{x} - \mathbf{x}_n) \right\rangle \quad (6.98)$$

If the free “charges” also possess intrinsic magnetic moments, these can be included in the definition of \mathbf{M} in an obvious way. The last terms in (6.96) involve the electric molecular moments and molecular velocities and cannot be given an easy interpretation, except in special cases (see below).

When $\langle \mathbf{j} \rangle$ is inserted in the second equation of (6.77), there results the macroscopic Ampère–Maxwell equation of (6.70) with the derived magnetic field quantity \mathbf{H} given in terms of \mathbf{B} and the properties of the medium as

$$\frac{1}{4\pi} (\mathbf{B} - \mathbf{H})_\alpha = M_\alpha + \left\langle \sum_{n \text{ (molecules)}} \left(\mathbf{p}_n \times \frac{\mathbf{v}_n}{c} \right)_\alpha \delta(\mathbf{x} - \mathbf{x}_n) \right\rangle - \frac{1}{6} \sum_{\beta\gamma\delta} \epsilon_{\alpha\beta\gamma} \frac{\partial}{\partial x_\delta} \left\langle \sum_{n \text{ (molecules)}} (Q'_n)_{\delta\beta} \frac{(\mathbf{v}_n)_\gamma}{c} \delta(\mathbf{x} - \mathbf{x}_n) \right\rangle + \cdots \quad (6.99)$$

The first term of the right-hand side of (6.99) is the familiar result, (6.71). The other terms are generally extremely small, first, because the molecular velocities \mathbf{v}_n are small, typically thermal velocities in a gas or lattice vibrational velocities in a solid and, second, because the velocities fluctuate and tend to average to zero macroscopically. An exception to this is when the medium undergoes bulk motion. For simplicity, suppose that the medium as a whole has a translational velocity \mathbf{v} . Neglecting any other motion of the molecules, we put $\mathbf{v}_n = \mathbf{v}$ for all n . Then (6.99) becomes, after a little manipulation,

$$\mathbf{B} - \mathbf{H} = 4\pi \mathbf{M} + (\mathbf{D} - \mathbf{E}) \times \frac{\mathbf{v}}{c} \quad (6.100)$$

where \mathbf{D} is given by (6.92). This shows that for a medium in motion the electric polarization \mathbf{P} (and quadrupole density $Q_{\alpha\beta}$) enter the effective magnetization. Equation (6.100) is the nonrelativistic limit of one of the equations of Minkowski's electrodynamics of moving media (see *Pauli*, p. 105).

The reader may consult the book by *de Groot* for a discussion of the relativistic corrections, as well as for a statistical mechanical treatment of the averaging. From the standpoint of logic and consistency there remains one loose end. In defining the molecular quadrupole moment $(Q'_n)_{\alpha\beta}$ by (6.84) we departed from our convention of Chapter 4, Eq. (4.9), and left $(Q'_n)_{\alpha\beta}$ with a nonvanishing trace. Since we made a point in Chapter 4 of relating the *five* independent components of the traceless quadrupole moment tensor to the $(2l+1)$ spherical harmonics for $l=2$, we need to explain why *six* components enter the macroscopic Maxwell equations. If we define a *traceless* molecular quadrupole moment $(Q_n)_{\alpha\beta}$ by means of (4.9), then we have

$$(Q'_n)_{\alpha\beta} = (Q_n)_{\alpha\beta} + \sum_{j(n)} q_j(\mathbf{x}_{jn})^2 \delta_{\alpha\beta} \quad (6.101)$$

Introducing a mean square charge radius r_n^2 of the molecular charge distribution by

$$er_n^2 = \sum_{j(n)} q_j(\mathbf{x}_{jn})^2$$

where e is some convenient unit of charge, for example, that of a proton, we can write (6.101) as

$$(Q'_n)_{\alpha\beta} = (Q_n)_{\alpha\beta} + er_n^2 \delta_{\alpha\beta}$$

The macroscopic quadrupole density (6.90) thus becomes

$$Q'_{\alpha\beta} = Q_{\alpha\beta} + \frac{1}{6} \left\langle \sum_n \left(\text{molecules} \right) er_n^2 \delta_{\alpha\beta} \delta(\mathbf{x} - \mathbf{x}_n) \right\rangle$$

where $Q_{\alpha\beta}$ is defined in terms of $(Q_n)_{\alpha\beta}$ just as in (6.90). The net result is that in the averaged microscopic charge density (6.87) the traceless quadrupole density $Q_{\alpha\beta}$ replaces the density $Q'_{\alpha\beta}$ and the charge density ρ is augmented by an additional term,

$$\rho \rightarrow \rho_{\text{free}} + \left\langle \sum_n \left(\text{molecules} \right) q_n \delta(\mathbf{x} - \mathbf{x}_n) \right\rangle + \frac{1}{6} \nabla^2 \left\langle \sum_n \left(\text{molecules} \right) er_n^2 \delta(\mathbf{x} - \mathbf{x}_n) \right\rangle \quad (6.102)$$

The trace of the tensor $Q'_{\alpha\beta}$ is exhibited with the charge density because it is an $l=0$ contribution in terms of the multipole expansion. The molecular charge and mean square radius terms together actually represent the first two terms in an expansion of the $l=0$ molecular multipole as we go beyond the static limit. In the Fourier transformed wave number space, they correspond to the first two terms in the expansion of the charge form factor in powers of k^2 . This can be seen from the definition of the form factor $F(k^2)$ for a charge density $\rho(\mathbf{x})$:

$$\begin{aligned} F(k^2) &= \int d^3x \rho(\mathbf{x}) \langle e^{i\mathbf{k} \cdot \mathbf{x}} \rangle_{l=0 \text{ part}} \\ &= \int d^3x \rho(\mathbf{x}) \frac{\sin kr}{kr} \\ &\approx \int \rho d^3x - \frac{1}{6} k^2 \int r^2 \rho d^3x + \dots \end{aligned}$$

With the correspondence $k \leftrightarrow -i\nabla$, the general equivalence of the form factor expansion and (6.102) is established.

In an interesting monograph, *Robinson* gives a discussion of the connection between the microscopic equations and the macroscopic equations similar to ours. However, he makes a distinction between the spatial averaging (6.73) with the test function $f(\mathbf{x})$, called "truncation" (of the wave number spectrum) by him, and the statistical-mechanical averaging over various sorts of ensembles. Robinson holds that each macroscopic problem has its own appropriate lower limit of relevant lengths and that this sets the size of the test function to be used, before any considerations of statistical averaging are made.

6.8 Poynting's Theorem and Conservation of Energy and Momentum for a System of Charged Particles and Electromagnetic Fields

The forms of the laws of conservation of energy and momentum are important results to establish for the electromagnetic field. We begin by considering conservation of energy, often called *Poynting's theorem* (1884). For a single charge q the rate of doing work by external electromagnetic fields \mathbf{E} and \mathbf{B} is $q\mathbf{v} \cdot \mathbf{E}$, where \mathbf{v} is the velocity of the charge. The magnetic field does no work, since the magnetic force is perpendicular to the velocity. If there exists a continuous distribution of charge and current, the total rate of doing work by the fields in a finite volume V is

$$\int_V \mathbf{J} \cdot \mathbf{E} d^3x \quad (6.103)$$

This power represents a conversion of electromagnetic energy into mechanical or thermal energy. It must be balanced by a corresponding rate of decrease of energy in the electromagnetic field within the volume V . In order to exhibit this conservation law explicitly, we use the Maxwell equations to express (6.103) in other terms. Thus we use the Ampère–Maxwell law to eliminate \mathbf{J} :

$$\int_V \mathbf{J} \cdot \mathbf{E} d^3x = \frac{1}{4\pi} \int_V \left[c\mathbf{E} \cdot (\nabla \times \mathbf{H}) - \mathbf{E} \cdot \frac{\partial \mathbf{D}}{\partial t} \right] d^3x \quad (6.104)$$

If we now employ the vector identity,

$$\nabla \cdot (\mathbf{E} \times \mathbf{H}) = \mathbf{H} \cdot (\nabla \times \mathbf{E}) - \mathbf{E} \cdot (\nabla \times \mathbf{H})$$

and use Faraday's law, the right side of (6.104) becomes

$$\int_V \mathbf{J} \cdot \mathbf{E} d^3x = \frac{-1}{4\pi} \int_V \left[c\nabla \cdot (\mathbf{E} \times \mathbf{H}) + \mathbf{E} \cdot \frac{\partial \mathbf{D}}{\partial t} + \mathbf{H} \cdot \frac{\partial \mathbf{B}}{\partial t} \right] d^3x \quad (6.105)$$

To proceed further we make two assumptions. We assume that the macroscopic medium involved is *linear* in its electric and magnetic properties. Then the two time derivatives in (6.105) can be interpreted, according to equations (4.89) and (6.16), as the time derivatives of the electrostatic and magnetic energy densities. We now make our second assumption, namely, that the sum of (4.89) and (6.16) represents the total electromagnetic energy, even for time-varying fields. Then if the total energy density is denoted by

$$u = \frac{1}{8\pi} (\mathbf{E} \cdot \mathbf{D} + \mathbf{B} \cdot \mathbf{H}) \quad (6.106)$$

(6.105) can be written

$$-\int_V \mathbf{J} \cdot \mathbf{E} d^3x = \int_V \left[\frac{\partial u}{\partial t} + \frac{c}{4\pi} \nabla \cdot (\mathbf{E} \times \mathbf{H}) \right] d^3x \quad (6.107)$$

Since the volume V is arbitrary, this can be cast into the form of a differential

continuity equation or conservation law,

$$\frac{\partial u}{\partial t} + \nabla \cdot \mathbf{S} = -\mathbf{J} \cdot \mathbf{E} \quad (6.108)$$

The vector \mathbf{S} , representing energy flow, is called the *Poynting vector*. It is given by

$$\mathbf{S} = \frac{c}{4\pi} (\mathbf{E} \times \mathbf{H}) \quad (6.109)$$

and has the dimensions of (energy/area \times time). Since only its divergence appears in the conservation law, the Poynting vector is arbitrary to the extent that the curl of any vector field can be added to it. Such an added term can, however, have no physical consequences. Hence it is customary to make the specific choice (6.109).

The physical meaning of the integral or differential form (6.107) or (6.108) is that the time rate of change of electromagnetic energy within a certain volume, plus the energy flowing out through the boundary surfaces of the volume per unit time, is equal to the negative of the total work done by the fields on the sources within the volume. This is the statement of conservation of energy. If dissipative effects, such as hysteresis in ferromagnetic materials, are envisioned, the simple law (6.108) is no longer valid, but must be supplemented by terms giving the hysteresis power loss.

The emphasis so far has been on the energy of the electromagnetic fields. The work done per unit time per unit volume by the fields ($\mathbf{J} \cdot \mathbf{E}$) is a conversion of electromagnetic into mechanical or heat energy. Since matter is ultimately composed of charged particles (electrons and atomic nuclei), we can think of this rate of conversion as a rate of increase of energy of the charged particles per unit volume. Then we can interpret Poynting's theorem for the *microscopic* fields (\mathbf{E} , \mathbf{B}) as a statement of conservation of energy of the combined system of particles and fields. If we denote the total energy of the particles within the volume V as E_{mech} and assume that no particles move out of the volume, we have

$$\frac{dE_{\text{mech}}}{dt} = \int_V \mathbf{J} \cdot \mathbf{E} d^3x \quad (6.110)$$

Then Poynting's theorem expresses the conservation of energy for the combined system as

$$\frac{dE}{dt} = \frac{d}{dt} (E_{\text{mech}} + E_{\text{field}}) = - \oint_S \mathbf{n} \cdot \mathbf{S} da \quad (6.111)$$

where the total field energy within V is

$$E_{\text{field}} = \int_V u d^3x = \frac{1}{8\pi} \int_V (\mathbf{E}^2 + \mathbf{B}^2) d^3x \quad (6.112)$$

The conservation of linear momentum can be similarly considered. The total electromagnetic force on a charged particle is

$$\mathbf{F} = q \left(\mathbf{E} + \frac{\mathbf{v}}{c} \times \mathbf{B} \right) \quad (6.113)$$

If the sum of all the momenta of all the particles in the volume V is denoted by \mathbf{P}_{mech} , we can write, from Newton's second law,

$$\frac{d\mathbf{P}_{\text{mech}}}{dt} = \int_V \left(\rho \mathbf{E} + \frac{1}{c} \mathbf{J} \times \mathbf{B} \right) d^3x \quad (6.114)$$

where we have converted the sum over particles to an integral over charge and current densities for convenience in manipulation. In the same manner as for Poynting's theorem, we use the Maxwell equations to eliminate ρ and \mathbf{J} from (6.114):

$$\rho = \frac{1}{4\pi} \nabla \cdot \mathbf{E}, \quad \mathbf{J} = \frac{c}{4\pi} \left(\nabla \times \mathbf{B} - \frac{1}{c} \frac{\partial \mathbf{E}}{\partial t} \right) \quad (6.115)$$

With (6.115) substituted into (6.114) the integrand becomes

$$\rho \mathbf{E} + \frac{1}{c} \mathbf{J} \times \mathbf{B} = \frac{1}{4\pi} \left[\mathbf{E}(\nabla \cdot \mathbf{E}) + \frac{1}{c} \mathbf{B} \times \frac{\partial \mathbf{E}}{\partial t} - \mathbf{B} \times (\nabla \times \mathbf{B}) \right]$$

Then writing

$$\mathbf{B} \times \frac{\partial \mathbf{E}}{\partial t} = - \frac{\partial}{\partial t} (\mathbf{E} \times \mathbf{B}) + \mathbf{E} \times \frac{\partial \mathbf{B}}{\partial t}$$

and adding $\mathbf{B}(\nabla \cdot \mathbf{B}) = 0$ to the square bracket, we obtain

$$\rho \mathbf{E} + \frac{1}{c} \mathbf{J} \times \mathbf{B} = \frac{1}{4\pi} \left[\mathbf{E}(\nabla \cdot \mathbf{E}) + \mathbf{B}(\nabla \cdot \mathbf{B}) - \mathbf{E} \times (\nabla \times \mathbf{E}) - \mathbf{B} \times (\nabla \times \mathbf{B}) \right] - \frac{1}{4\pi c} \frac{\partial}{\partial t} (\mathbf{E} \times \mathbf{B})$$

The rate of change of mechanical momentum (6.114) can now be written

$$\begin{aligned} \frac{d\mathbf{P}_{\text{mech}}}{dt} + \frac{d}{dt} \int_V \frac{1}{4\pi c} (\mathbf{E} \times \mathbf{B}) d^3x \\ = \frac{1}{4\pi} \int_V [\mathbf{E}(\nabla \cdot \mathbf{E}) - \mathbf{E} \times (\nabla \times \mathbf{E}) + \mathbf{B}(\nabla \cdot \mathbf{B}) - \mathbf{B} \times (\nabla \times \mathbf{B})] d^3x \end{aligned} \quad (6.116)$$

We may tentatively identify the volume integral on the left as the total electromagnetic momentum $\mathbf{P}_{\text{field}}$ in the volume V :

$$\mathbf{P}_{\text{field}} = \frac{1}{4\pi c} \int_V (\mathbf{E} \times \mathbf{B}) d^3x \quad (6.117)$$

The integrand can be interpreted as a density of electromagnetic momentum. We note that this momentum density is proportional to the energy-flux density \mathbf{S} , with proportionality constant c^{-2} .

To complete the identification of the volume integral of

$$\mathbf{g} = \frac{1}{4\pi c} (\mathbf{E} \times \mathbf{B}) \quad (6.118)$$

as electromagnetic momentum, and to establish (6.116) as the conservation law for momentum, we must convert the volume integral on the right into a surface integral of the normal component of something which can be identified as momentum flow. Let the Cartesian coordinates be denoted by x_α , $\alpha = 1, 2, 3$. The $\alpha = 1$ component of the electric part of the integrand in (6.116) is given explicitly by

$$\begin{aligned} [\mathbf{E}(\nabla \cdot \mathbf{E}) - \mathbf{E} \times (\nabla \times \mathbf{E})]_1 &= E_1 \left(\frac{\partial E_1}{\partial x_1} + \frac{\partial E_2}{\partial x_2} + \frac{\partial E_3}{\partial x_3} \right) - E_2 \left(\frac{\partial E_2}{\partial x_1} - \frac{\partial E_1}{\partial x_2} \right) + E_3 \left(\frac{\partial E_1}{\partial x_3} - \frac{\partial E_3}{\partial x_1} \right) \\ &= \frac{\partial}{\partial x_1} (E_1^2) + \frac{\partial}{\partial x_2} (E_1 E_2) + \frac{\partial}{\partial x_3} (E_1 E_3) - \frac{1}{2} \frac{\partial}{\partial x_1} (E_1^2 + E_2^2 + E_3^2) \end{aligned}$$

This means that we can write the α th component as

$$[\mathbf{E}(\nabla \cdot \mathbf{E}) - \mathbf{E} \times (\nabla \times \mathbf{E})]_\alpha = \sum_\beta \frac{\partial}{\partial x_\beta} (E_\alpha E_\beta - \frac{1}{2} \mathbf{E} \cdot \mathbf{E} \delta_{\alpha\beta}) \quad (6.119)$$

and have the form of a divergence of a second rank tensor on the right-hand side. With the definition of the *Maxwell stress tensor* $T_{\alpha\beta}$ as

$$T_{\alpha\beta} = \frac{1}{4\pi} [E_\alpha E_\beta + B_\alpha B_\beta - \frac{1}{2} (\mathbf{E} \cdot \mathbf{E} + \mathbf{B} \cdot \mathbf{B}) \delta_{\alpha\beta}] \quad (6.120)$$

Eq. (6.116) can therefore be written in component form as

$$\frac{d}{dt} (\mathbf{P}_{\text{mech}} + \mathbf{P}_{\text{field}})_\alpha = \sum_\beta \int_V \frac{\partial}{\partial x_\beta} T_{\alpha\beta} d^3x \quad (6.121)$$

Application of the divergence theorem to the volume integral gives

$$\frac{d}{dt} (\mathbf{P}_{\text{mech}} + \mathbf{P}_{\text{field}})_\alpha = \oint_S \sum_\beta T_{\alpha\beta} n_\beta da \quad (6.122)$$

where \mathbf{n} is the outward normal to the closed surface S . Evidently, if (6.122) represents a statement of conservation of momentum, $\sum_\beta T_{\alpha\beta} n_\beta$ is the α th component of the flow per unit area of momentum across the surface S into the volume V . In other words, it is the force per unit area transmitted across the surface S and acting on the combined system of particles and fields inside V . Equation (6.122) can therefore be used to calculate the forces acting on material objects in electromagnetic fields by enclosing the objects with a boundary surface S and adding up the total electromagnetic force according to the right-hand side of (6.122).

The conservation of angular momentum of the combined system of particles

and fields can be treated in the same way as we have handled energy and linear momentum. This is left as a problem for the student (see Problem 6.11).

6.9 Conservation Laws for Macroscopic Media

In the previous section Poynting's theorem was derived using the macroscopic Maxwell equations, but the conservation of momentum and the Maxwell stress tensor were discussed only for the microscopic equations. For bulk matter considerable care must be exercised in defining the *electromagnetic* energy density u , energy flow \mathbf{S} , momentum flow \mathbf{g} , and stress tensor $T_{\alpha\beta}$ because what is considered electromagnetic and what mechanical is to some extent arbitrary. This question has occupied many workers over the years. Historical accounts can be found in *Pauli* and *de Groot*. We will content ourselves with a few observations.

If one makes a straightforward application of the *macroscopic* Maxwell equations to the conservation of momentum as well as energy, one obtains what are generally called the Minkowski (1908) results, even though some were proposed earlier by others. These are the previously obtained expressions (6.106) for u and (6.109) for \mathbf{S} , but with the momentum density and stress tensor given by

$$\mathbf{g} = \frac{1}{4\pi c} (\mathbf{D} \times \mathbf{B}) \quad (6.123)$$

and

$$T_{\alpha\beta} = \frac{1}{4\pi} [E_\alpha D_\beta + H_\alpha B_\beta - \frac{1}{2}(\mathbf{E} \cdot \mathbf{D} + \mathbf{B} \cdot \mathbf{H})\delta_{\alpha\beta}] \quad (6.124)$$

The medium is assumed to be linear, but not necessarily isotropic, in its response. Note that the stress tensor is not symmetric for anisotropic media. This lack of symmetry has disturbed many physicists, Hertz and Abraham being among the first to replace (6.124) with a symmetrized form. Experimental tests are not as easy to come by as one might first imagine. Brevik* discusses the various versions of $T_{\alpha\beta}$ in detail and concludes by favoring the unsymmetrical Minkowski form.

The Minkowski expression (6.123) for \mathbf{g} is generally viewed as unacceptable as the electromagnetic momentum density. All workers agree on the definition

$$\mathbf{g} = \frac{1}{4\pi c} (\mathbf{E} \times \mathbf{H}) = \frac{1}{c^2} \mathbf{S} \quad (6.125)$$

This result emerges from a statistical mechanical treatment of the system of matter plus fields in which the *electromagnetic quantities* are defined as the

* I. Brevik, *Dankse Videns. Sels. Mat.-fys. Medd.* **37**, No. 11 and No. 13 (1970).

difference between the quantities for the combined system and those for the matter system at the same equilibrium temperature T and density ρ , but with zero fields. With this definition, the momentum and energy flow densities are given by (6.125) and (6.109), while, for a medium that is linear and isotropic with $\mathbf{D} = \epsilon \mathbf{E}$ and $\mathbf{B} = \mu \mathbf{H}$, the electromagnetic part of the internal energy is*

$$u = \frac{1}{8\pi} \left\{ E^2 \left[\epsilon + T \left(\frac{\partial \epsilon}{\partial T} \right)_\rho \right] + H^2 \left[\mu + T \left(\frac{\partial \mu}{\partial T} \right)_\rho \right] \right\} \quad (6.126)$$

while the electromagnetic stress tensor is

$$T_{\alpha\beta} = \frac{1}{4\pi} \left\{ \epsilon E_\alpha E_\beta + \mu H_\alpha H_\beta - \frac{1}{2} \delta_{\alpha\beta} \left[E^2 \left(\epsilon - \rho \left(\frac{\partial \epsilon}{\partial \rho} \right)_T \right) + H^2 \left(\mu - \rho \left(\frac{\partial \mu}{\partial \rho} \right)_T \right) \right] \right\} \quad (6.127)$$

These reduce to the Minkowski expressions for u and $T_{\alpha\beta}$ only for the unphysical situation in which ϵ and μ are independent of temperature and density.

The subject of energy and momentum balance for bulk matter in electromagnetic fields is evidently complicated. We refer the reader to *Landau and Lifshitz (loc. cit.)* and also to *Stratton*, Chapter 2, for further discussion.

6.10 Poynting's Theorem for Harmonic Fields, Field Definitions of Impedance and Admittance†

Lumped circuit concepts such as the resistance and reactance of a two-terminal linear network occur in many applications, even in circumstances where the size of the system is comparable to the free space wavelength, for example, for a resonant antenna. It is useful therefore to have a general definition based on field concepts. This follows from consideration of Poynting's theorem for harmonic time variation of the fields. We assume that all fields and sources have a time dependence $e^{-i\omega t}$, so that we write

$$\mathbf{E}(\mathbf{x}, t) = \text{Re} [\mathbf{E}(\mathbf{x}) e^{-i\omega t}] \equiv \frac{1}{2} [\mathbf{E}(\mathbf{x}) e^{-i\omega t} + \mathbf{E}^*(\mathbf{x}) e^{i\omega t}] \quad (6.128)$$

The field $\mathbf{E}(\mathbf{x})$ is in general complex, with a magnitude and phase that change with position. For product forms, such as $\mathbf{J}(\mathbf{x}, t) \cdot \mathbf{E}(\mathbf{x}, t)$, we have

$$\begin{aligned} \mathbf{J}(\mathbf{x}, t) \cdot \mathbf{E}(\mathbf{x}, t) &= \frac{1}{4} [\mathbf{J}(\mathbf{x}) e^{-i\omega t} + \mathbf{J}^*(\mathbf{x}) e^{i\omega t}] \cdot [\mathbf{E}(\mathbf{x}) e^{-i\omega t} + \mathbf{E}^*(\mathbf{x}) e^{i\omega t}] \\ &= \frac{1}{2} \text{Re} [\mathbf{J}^*(\mathbf{x}) \cdot \mathbf{E}(\mathbf{x}) + \mathbf{J}(\mathbf{x}) \cdot \mathbf{E}(\mathbf{x}) e^{-2i\omega t}] \end{aligned} \quad (6.129)$$

* See *de Groot*, Section 13, or *Landau and Lifshitz, Electrodynamics of Continuous Media*, Sections 10, 15, 30, 34.

† The treatment of this section parallels that of *Fano, Chu, and Adler*, Sections 8.2 and 8.3. The reader can find in this book considerable further discussion of the connection between lumped circuit and field concepts, examples of stray capacitances in inductors, etc. See also the first two chapters of *Adler, Chu, and Fano*.

For time-averages of products the convention is therefore to take one-half of the real part of the product of one complex quantity with the complex conjugate of the other.

For harmonic fields the Maxwell equations become

$$\begin{aligned}\nabla \cdot \mathbf{B} &= 0, & \nabla \times \mathbf{E} - i \frac{\omega}{c} \mathbf{B} &= 0 \\ \nabla \cdot \mathbf{D} &= 4\pi\rho, & \nabla \times \mathbf{H} + i \frac{\omega}{c} \mathbf{D} &= \frac{4\pi}{c} \mathbf{J}\end{aligned}\quad (6.130)$$

where all the quantities are complex functions of \mathbf{x} , according to the right-hand side of (6.128). Instead of (6.103) we consider the volume integral

$$\frac{1}{2} \int_V \mathbf{J}^* \cdot \mathbf{E} d^3x$$

whose real part gives the time-average rate of work done by the fields in the volume V . In a development strictly paralleling the steps from (6.103) to (6.107) we have

$$\begin{aligned}\frac{1}{2} \int_V \mathbf{J}^* \cdot \mathbf{E} d^3x &= \frac{c}{8\pi} \int_V \mathbf{E} \cdot \left[\nabla \times \mathbf{H}^* - i \frac{\omega}{c} \mathbf{D}^* \right] d^3x \\ &= \frac{c}{8\pi} \int_V \left[-\nabla \cdot (\mathbf{E} \times \mathbf{H}^*) - i \frac{\omega}{c} (\mathbf{E} \cdot \mathbf{D}^* - \mathbf{B} \cdot \mathbf{H}^*) \right] d^3x\end{aligned}\quad (6.131)$$

We now define the complex Poynting vector,

$$\mathbf{S} = \frac{c}{8\pi} (\mathbf{E} \times \mathbf{H}^*) \quad (6.132)$$

and the harmonic electric and magnetic energy densities,

$$w_e = \frac{1}{16\pi} (\mathbf{E} \cdot \mathbf{D}^*), \quad w_m = \frac{1}{16\pi} (\mathbf{B} \cdot \mathbf{H}^*) \quad (6.133)$$

Then (6.131) can be written as

$$\frac{1}{2} \int_V \mathbf{J}^* \cdot \mathbf{E} d^3x + 2i\omega \int_V (w_e - w_m) d^3x + \oint_S \mathbf{S} \cdot \mathbf{n} da = 0 \quad (6.134)$$

This is the analog of (6.107) for harmonic fields. It is a complex equation whose real part gives the conservation of energy for the time-averaged quantities and whose imaginary part relates to the reactive or stored energy and its alternating flow. If the energy densities w_e and w_m have real volume integrals, as occurs for systems with lossless dielectrics and perfect conductors, the real part of (6.134) is

$$\int_V \frac{1}{2} \operatorname{Re} (\mathbf{J}^* \cdot \mathbf{E}) d^3x + \oint_S \operatorname{Re} (\mathbf{S} \cdot \mathbf{n}) da = 0$$

showing that the steady-state time-average rate of doing work on the sources in V by the fields is equal to the average flow of power *into* the volume V through the boundary surface S , as calculated from the normal component of $\text{Re } \mathbf{S}$. This is just what would be calculated from the earlier form of Poynting's theorem (6.107) if we assume that the energy density u has a steady part and a harmonically fluctuating part. With losses in the components of the system, the second term in (6.134) has a real part that accounts for this dissipation.

The complex Poynting theorem (6.134) can be used to define the input impedance of a general, two-terminal, linear, passive electromagnetic system. We imagine the system in the volume V surrounded by the boundary surface S , with only its input terminals protruding, as shown in Fig. 6.6. If the complex harmonic input current and voltage are I_i and V_i , the complex power input is $\frac{1}{2}I_i^* V_i$. This can be written in terms of the Poynting vector by using (6.134) applied to all of space on the *outside* of S as

$$\frac{1}{2}I_i^* V_i = - \oint_{S_i} \mathbf{S} \cdot \mathbf{n} \, da \quad (6.135)$$

where the unit normal \mathbf{n} is outwardly directed, as shown in Fig. 6.6, and we have

Fig. 6.6 Schematic diagrams of arbitrary, two-terminal, linear, passive electromagnetic systems. The surface S completely surrounds the system; only the input terminals protrude. At these terminals, the harmonic input current and voltage are I_i and V_i , with the input impedance Z defined by $V_i = ZI_i$. The upper diagram applies at low frequencies where radiation losses are negligible, while the lower one with its coaxial-line input permits discussion of radiation resistance.

assumed that the input power flow is confined to the area S_i (the cross-section of the coaxial line in the lower diagram of Fig. 6.6). By now considering (6.134) for the volume V surrounded by the closed surface S , the right-hand side of (6.135) can be written in terms of integrals over the fields inside the volume V :

$$\frac{1}{2}I_i^* V_i = \frac{1}{2} \int_V \mathbf{J}^* \cdot \mathbf{E} d^3x + 2i\omega \int_V (w_e - w_m) d^3x + \oint_{S-S_i} \mathbf{S} \cdot \mathbf{n} da \quad (6.136)$$

The surface integral here represents power flow out of the volume V through the surface S , except for the input surface S_i . If the surface $(S-S_i)$ is taken to infinity, this integral is real and represents escaping radiation (see Chapter 9). At low frequencies it is generally negligible. Then no distinction need be made between S_i and S ; the upper diagram in Fig. 6.6 applies.

The input impedance $Z = R - iX$ (electrical engineers please read as $Z = R + jX$!) follows from (6.136) with its definition, $V_i = ZI_i$. Its real and imaginary parts are

$$R = \frac{1}{|I_i|^2} \left\{ \text{Re} \int_V \mathbf{J}^* \cdot \mathbf{E} d^3x + 2 \oint_{S-S_i} \mathbf{S} \cdot \mathbf{n} da + 4\omega \text{Im} \int_V (w_m - w_e) d^3x \right\} \quad (6.137)$$

$$X = \frac{1}{|I_i|^2} \left\{ 4\omega \text{Re} \int_V (w_m - w_e) d^3x - \text{Im} \int_V \mathbf{J}^* \cdot \mathbf{E} d^3x \right\} \quad (6.138)$$

In writing (6.137) and (6.138) we have assumed that the power flow out through S is real. The second term in (6.137) is thus the “radiation resistance,” important at high frequencies. At low frequencies, in systems where Ohmic losses are the only appreciable source of dissipation, these expressions simplify to

$$R \approx \frac{1}{|I_i|^2} \int_V \sigma |\mathbf{E}|^2 d^3x \quad (6.139)$$

$$X \approx \frac{4\omega}{|I_i|^2} \int_V (w_m - w_e) d^3x \quad (6.140)$$

Here σ is the real conductivity, and the energy densities w_m and w_e (6.133) are also real over essentially the whole volume. The resistance is clearly the value expected from consideration of Ohmic heat loss in the circuit. Similarly, the reactance has a plausible form: If magnetic stored energy dominates, as for a lumped inductance, the reactance is positive, etc. The different frequency dependences of the low frequency reactance for inductances ($X = \omega L$) and capacitances ($X = -1/\omega C$) can be traced to the definition of L in terms of current and voltage ($V = L dI/dt$) on the one hand, and of C in terms of charge and voltage ($V = Q/C$) on the other. The treatment of some simple examples is left to the problems at the end of the chapter, as is the derivation of results equivalent to (6.139) and (6.140) for the conductance and susceptance of the complex admittance Y .

6.11 Transformation Properties of Electromagnetic Fields and Sources under Rotations, Spatial Reflections, and Time Reversal

The fact that related physical quantities have compatible transformation properties under certain types of coordinate transformations is so taken for granted that the significance of such requirements and the limitations that can be thereby placed on the form of the relations is sometimes overlooked. It is useful therefore to discuss explicitly the relatively obvious properties of electromagnetic quantities under rotations, spatial inversions, and time reversal. The notions have direct application for limiting phenomenological constitutive relations, and are applied in the next section where the question of magnetic monopoles is discussed.

It is assumed that the idea of space and time coordinate transformations and their relation to the general conservation laws is familiar to the reader from classical mechanics (see *Goldstein*, for example). Only a summary of the main results is given here.

Rotations

A rotation in three dimensions is a linear transformation of the coordinates of a point such that the sum of the squares of the coordinates remains invariant. Such a transformation is called an orthogonal transformation. The transformed coordinates x'_α are given in terms of the original coordinates x_β by

$$x'_\alpha = \sum_\beta a_{\alpha\beta} x_\beta \quad (6.141)$$

The requirement that $(\mathbf{x}')^2 = (\mathbf{x})^2$ restricts the real transformation coefficients $a_{\alpha\beta}$ to be orthogonal,

$$\sum_\alpha a_{\alpha\beta} a_{\alpha\gamma} = \delta_{\beta\gamma} \quad (6.142)$$

The inverse transformation has $(a^{-1})_{\alpha\beta} = a_{\beta\alpha}$ and the square of the determinant of the matrix (a) is equal to unity. The value $\det(a) = +1$ corresponds to a proper rotation, obtainable from the original configuration by a sequence of infinitesimal steps, whereas $\det(a) = -1$ represents an improper rotation, a reflection plus a rotation.

Physical quantities are classed as rotational tensors of various ranks depending on how they transform under rotations. Coordinates \mathbf{x}_i , velocities \mathbf{v}_i , momenta \mathbf{p}_i have components that transform according to the basic transformation law (6.141) and are tensors of rank one, or *vectors*. Scalar products of vectors, such as $\mathbf{x}_1 \cdot \mathbf{x}_2$ or $\mathbf{v}_1 \cdot \mathbf{p}_2$, are invariant under rotations and so are tensors of rank zero, or *scalars*. Groups of quantities that transform according to

$$B'_{\alpha\beta} = \sum_{\gamma,\delta} a_{\alpha\gamma} a_{\beta\delta} B_{\gamma\delta} \quad (6.143)$$

are called second rank tensors or, commonly, *tensors*. The Maxwell stress tensor is one such group of quantities. Higher rank tensor transformations follow obviously.

In considering electromagnetic fields and other physical quantities, we deal with one or more functions of coordinates and perhaps other kinematic variables. There then arises the choice of an “active” or a “passive” view of the rotation. We adopt the active view—the coordinate axes are considered fixed and the physical system is imagined to undergo a rotation. Thus, for example, two charged particles with initial coordinates \mathbf{x}_1 and \mathbf{x}_2 form a system that under a rotation is transformed so that the coordinates of the particles are now \mathbf{x}'_1 and \mathbf{x}'_2 , as shown in Fig. 6.7. The components of each coordinate vector transform according to (6.141), but electrostatic potential is unchanged because it is a function only of the distance between the two points, $R = |\mathbf{x}_1 - \mathbf{x}_2|$, and R^2 is a sum of scalar products of vectors and so is invariant under the rotation. The electrostatic potential is one example of a scalar under rotations. In general, if a physical quantity ϕ , which is a function of various coordinates denoted collectively by \mathbf{x}_i (possibly including coordinates such as velocities and momenta), is such that, when the physical system is rotated with $\mathbf{x}_i \rightarrow \mathbf{x}'_i$, the quantity remains unchanged,

$$\phi'(\mathbf{x}'_i) = \phi(\mathbf{x}_i) \quad (6.144)$$

then ϕ is a scalar function under rotations. Similarly, if a set of three physical

Fig. 6.7 Active rotation of a system of two charges.

quantities $V_\alpha(\mathbf{x}_i)$ ($\alpha = 1, 2, 3$) transform under rotation of the system according to

$$V'_\alpha(\mathbf{x}'_i) = \sum_\beta a_{\alpha\beta} V_\beta(\mathbf{x}_i) \quad (6.145)$$

then the V_α form the components of a vector, and so on for higher rank tensors.

Differential vector operations have definite transformation properties under rotations. For example, the gradient of a scalar, $\nabla\phi$, transforms as a vector, the divergence of a vector, $\nabla \cdot \mathbf{V}$, is a scalar, and the Laplacian operator ∇^2 is a scalar operator in the sense that its application to a function or set of functions does not alter their rotational transformation properties.

Special mention must be made of the cross product of two vectors:

$$\mathbf{A} = \mathbf{B} \times \mathbf{C} \quad (6.146)$$

In component form this vector shorthand reads

$$A_\alpha = \sum_{\beta\gamma} \epsilon_{\alpha\beta\gamma} B_\beta C_\gamma$$

where $\epsilon_{\alpha\beta\gamma} = +1$ for $\alpha = 1, \beta = 2, \gamma = 3$ and cyclic permutations, $\epsilon_{\alpha\beta\gamma} = -1$ for other permutations, and vanishes for two or more indices equal. Because of the presence of two vectors on the right-hand side, the cross product has some attributes of a traceless antisymmetric second rank tensor. Since such a tensor has only three independent components, we treat it as a vector. This has justification, of course, only in so far as it transforms under rotations according to (6.141). In actual fact, the transformation law for the cross product (6.146) is

$$A'_\alpha = \det(a) \sum_\beta a_{\alpha\beta} A_\beta \quad (6.147)$$

For proper rotations, the only kind that we have considered so far, $\det(a) = +1$; thus (6.147) is in agreement with the basic coordinate transformation (6.141). Under proper rotations, the cross product transforms as a vector.

Spatial Reflection or Inversion

Spatial reflection in a plane corresponds to changing the signs of the normal components of the coordinate vectors of all points and to leaving the components parallel to the plane unchanged. Thus, for reflection in the x - y plane, $\mathbf{x}_i = (x_i, y_i, z_i) \rightarrow \mathbf{x}'_i = (x_i, y_i, -z_i)$. Space inversion corresponds to reflection of all three components of every coordinate vector through the origin, $\mathbf{x}_i \rightarrow \mathbf{x}'_i = -\mathbf{x}_i$. Spatial inversion or reflection is a discrete transformation that, for more than two coordinates, cannot in general be accomplished by proper rotations. It corresponds to $\det(a) = -1$, and for the straightforward inversion operation is given by (6.141) with $a_{\alpha\beta} = -\delta_{\alpha\beta}$. It follows that vectors change sign under spatial inversion, but cross products, which behave according to (6.147), do not. We are

thus forced to distinguish two kinds of vectors (under general rotations):

Polar vectors (or just vectors) that transform according to (6.145) and for $\mathbf{x}_i \rightarrow \mathbf{x}'_i = -\mathbf{x}_i$ behave as

$$\mathbf{V} \rightarrow \mathbf{V}' = -\mathbf{V}$$

Axial or Pseudovectors that transform according to (6.147) and for $\mathbf{x}_i \rightarrow \mathbf{x}'_i = -\mathbf{x}_i$ behave as

$$\mathbf{A} \rightarrow \mathbf{A}' = \mathbf{A}$$

Similar distinctions must be made for scalars under rotations. We speak of *scalars* or *pseudoscalars*, depending on whether the quantities do not or do change sign under spatial inversion. The triple scalar product $\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})$ is an example of a pseudoscalar quantity, provided \mathbf{a} , \mathbf{b} , \mathbf{c} are all polar vectors. (We see here in passing a dangerous aspect of our usual notation. The writing of a vector as \mathbf{a} does not tell us whether it is a polar or an axial vector.) The transformation properties of higher rank tensors under spatial inversion can be deduced directly if they are built up by taking products of components of polar or axial vectors. If a tensor of rank N transforms under spatial inversion with a factor $(-1)^N$, we call it a true tensor or just a *tensor*, while if the factor is $(-1)^{N+1}$ we call it a *pseudotensor* of rank N .

Time Reversal

The basic laws of physics are invariant (at least at the classical level) to the sense of direction of time. This does not mean that the equations are even in t , but that, under the time reversal transformation $t \rightarrow t' = -t$, the related physical quantities transform in a consistent fashion so that the *form* of the equation is the same as before. Thus, for a particle of momentum \mathbf{p} and position \mathbf{x} moving in an external potential $U(\mathbf{x})$, Newton's equation of motion,

$$\frac{d\mathbf{p}}{dt} = -\nabla U(\mathbf{x})$$

is invariant under time reversal provided $\mathbf{x} \rightarrow \mathbf{x}' = \mathbf{x}$ and $\mathbf{p} \rightarrow \mathbf{p}' = -\mathbf{p}$. The sign change for the momentum is, of course, intuitively obvious from its relation to the velocity, $\mathbf{v} = d\mathbf{x}/dt$. The consequence of the invariance of Newton's laws under time reversal is that, if a certain initial configuration of a system of particles evolves under the action of various forces into some final configuration, a possible state of motion of the system is that the time-reversed final configuration (all positions the same, but all velocities reversed) will evolve over the reversed path to the time-reversed initial configuration.

The transformation properties of various mechanical quantities under rotations, spatial inversion, and time reversal are summarized in the first part of Table 6.1.

Table 6.1

Transformation Properties of Various Physical Quantities under Rotations, Spatial Inversion and Time Reversal^a

Physical Quantity		Rotation (Rank of Tensor)	Space Inversion (Name)	Time Reversal
I. Mechanical				
Coordinate	\mathbf{x}	1	Odd (vector)	Even
Velocity	\mathbf{v}	1	Odd (vector)	Odd
Momentum	\mathbf{p}	1	Odd (vector)	Odd
Angular momentum	$\mathbf{L} = \mathbf{x} \times \mathbf{p}$	1	Even (pseudovector)	Odd
Force	\mathbf{F}	1	Odd (vector)	Even
Torque	$\mathbf{N} = \mathbf{x} \times \mathbf{F}$	1	Even (pseudovector)	Even
Kinetic energy	$p^2/2m$	0	Even (scalar)	Even
Potential energy	$U(\mathbf{x})$	0	Even (scalar)	Even
II. Electromagnetic				
Charge density	ρ	0	Even (scalar)	Even
Current density	\mathbf{J}	1	Odd (vector)	Odd
Electric field	\mathbf{E}	1	Odd (vector)	Even
Polarization	\mathbf{P}			
Displacement	\mathbf{D}			
Magnetic induction	\mathbf{B}	1	Even (pseudovector)	Odd
Magnetization	\mathbf{M}			
Magnetic field	\mathbf{H}			
Poynting vector	$\mathbf{S} = \frac{c}{4\pi} (\mathbf{E} \times \mathbf{H})$	1	Odd (vector)	Odd
Maxwell stress tensor	$T_{\alpha\beta}$	2	Even (tensor)	Even

^a For quantities that are functions of \mathbf{x} and t , it is necessary to be very clear what is meant by evenness or oddness under space inversion or time reversal. For example, the magnetic induction is such that under space inversion, $\mathbf{B}(\mathbf{x}, t) \rightarrow \mathbf{B}_I(\mathbf{x}, t) = +\mathbf{B}(-\mathbf{x}, t)$, while under time reversal, $\mathbf{B}(\mathbf{x}, t) \rightarrow \mathbf{B}_T(\mathbf{x}, t) = -\mathbf{B}(\mathbf{x}, -t)$.

Electromagnetic Quantities

Just as with the laws of mechanics, it is true (i.e., consistent with all known experimental facts) that the forms of the equations governing electromagnetic phenomena are invariant under rotations, space inversion, and time reversal. This implies that the different electromagnetic quantities have well-defined transformation properties under these operations. It is an experimental fact that electric charge is invariant under Galilean and Lorentz transformations and is a scalar under rotations. It is natural, convenient, and permissible to assume that charge is also a scalar under spatial inversion and even under time reversal. The point here is that physically measurable quantities like force involve the product of charge and field. The transformation properties attributed to fields like \mathbf{E} and \mathbf{B} thus depend on the convention chosen for the charge.

With charge a true scalar under all three transformations, *charge density* ρ is also a *true scalar*. From the fact that the *electric field* is force per unit charge we see that \mathbf{E} is a *polar vector, even under time reversal*. This also follows from the Maxwell equation, $\nabla \cdot \mathbf{E} = 4\pi\rho$, since both sides must transform in the same manner under the transformations.

The first term in the Maxwell equation representing Faraday's law,

$$\nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} = 0$$

transforms as a pseudovector under rotations and spatial inversion, and is even under time reversal. To preserve the invariance of form it is therefore necessary that the *magnetic induction* \mathbf{B} be a *pseudovector, odd under time reversal*. The left-hand side of the Ampère-Maxwell equation,

$$\nabla \times \mathbf{B} - \frac{1}{c} \frac{\partial \mathbf{E}}{\partial t} = \frac{4\pi}{c} \mathbf{J}$$

can be seen to transform as a polar vector, odd under time reversal. This implies that the *current density* \mathbf{J} is a *polar vector, odd under time reversal*, as expected from its definition in terms of charge times velocity.

We have just seen that the microscopic fields and sources have well-defined transformation properties under rotations, spatial inversion, and time reversal. From the derivation of the macroscopic Maxwell equations in Section 6.7 and the definitions of \mathbf{P} , \mathbf{M} , etc., it can be seen that \mathbf{E} , \mathbf{P} , \mathbf{D} all transform in the same way, as do \mathbf{B} , \mathbf{M} , \mathbf{H} . The various transformation properties for electromagnetic quantities are summarized in the second part of Table 6.1.

To illustrate the usefulness of arguments on the symmetry properties listed in Table 6.1, we consider the phenomenological structure of a spatially local constitutive relation specifying the polarization \mathbf{P} for an isotropic, linear, nondissipative medium in a uniform, constant, external magnetic induction \mathbf{B}_0 . The relation is first order in the electric field \mathbf{E} , by assumption, but we require an expansion in powers of \mathbf{B}_0 up to second order. Since \mathbf{P} is a polar vector, and even under time reversal, the various terms to be multiplied by scalar coefficients must transform in the same way. To zeroth order in \mathbf{B}_0 , only \mathbf{E} is available. To first order in \mathbf{B}_0 , possible terms involving \mathbf{E} linearly are

$$\mathbf{E} \times \mathbf{B}_0, \quad \frac{\partial \mathbf{E}}{\partial t} \times \mathbf{B}_0, \quad \frac{\partial^2 \mathbf{E}}{\partial t^2} \times \mathbf{B}_0, \dots$$

All of these are permitted by rotational and spatial inversion grounds, but only those involving odd time derivatives transform properly under time reversal. For the second order in \mathbf{B}_0 , the possibilities are

$$(\mathbf{B}_0 \cdot \mathbf{B}_0)\mathbf{E}, \quad (\mathbf{E} \cdot \mathbf{B}_0)\mathbf{B}_0, \quad (\mathbf{B}_0 \cdot \mathbf{B}_0) \frac{\partial \mathbf{E}}{\partial t}, \dots$$

Here only the terms with zero or even time derivatives of \mathbf{E} satisfy all the requirements. The most general spatially local expression for the polarization, correct to second order in the constant magnetic field \mathbf{B}_0 , is thus

$$\mathbf{P} = \chi_0 \mathbf{E} + \chi_1 \frac{\partial \mathbf{E}}{\partial t} \times \mathbf{B}_0 + \chi_2 (\mathbf{B}_0 \cdot \mathbf{B}_0) \mathbf{E} + \chi_3 (\mathbf{E} \cdot \mathbf{B}_0) \mathbf{B}_0 + \cdots \quad (6.148)$$

where the χ_i are real coefficients and higher time derivatives of \mathbf{E} can occur, odd for the terms linear in \mathbf{B}_0 and even for the zeroth and second powers of \mathbf{B}_0 . At low frequencies, the response of essentially all material systems is via electric forces. This means that at zero frequency there should be no dependence of \mathbf{P} on \mathbf{B}_0 , and a more realistic form is

$$\mathbf{P} = \chi_0 \mathbf{E} + \chi_1 \frac{\partial \mathbf{E}}{\partial t} \times \mathbf{B}_0 + \chi_2' (\mathbf{B}_0 \cdot \mathbf{B}_0) \frac{\partial^2 \mathbf{E}}{\partial t^2} + \chi_3' \left(\frac{\partial^2 \mathbf{E}}{\partial t^2} \cdot \mathbf{B}_0 \right) \mathbf{B}_0 \quad (6.149)$$

where we have exhibited only the lowest order time derivatives for each power of \mathbf{B}_0 . At optical frequencies this equation permits an understanding of the gyrotropic behavior of waves in an isotropic medium in a constant magnetic field.*

Another example, the Hall effect, is left to the problems. It, as well as thermogalvanomagnetic effects and the existence of magnetic structure in solids, are discussed in *Landau and Lifshitz (op. cit.)*.

6.12 On the Question of Magnetic Monopoles

At the present time (1975) there is no experimental evidence for the existence of magnetic charges or monopoles, but chiefly because of an early, brilliant theoretical argument of Dirac,[†] the search for monopoles is renewed whenever a new energy region is opened up in high energy physics or a new source of matter, such as rocks from the moon, becomes available. Dirac's argument, outlined below, is that the mere existence of one magnetic monopole in the universe would offer an explanation of the discrete nature of electric charge. Since the quantization of charge is one of the most profound mysteries of the physical world, Dirac's idea has great appeal. The history of the theoretical ideas and experimental searches up to 1968 are described in a review article by Amaldi.[‡] Some references to more recent literature appear at the end of the chapter.

* See Landau and Lifshitz, *Electrodynamics of Continuous Media*, p. 334, Problem 3, p. 337.

† P. A. M. Dirac, *Proc. Roy. Soc. A* **133**, 60 (1931); *Phys. Rev.* **74**, 817 (1948).

‡ E. Amaldi, "On the Dirac Magnetic Poles," in *Old and New Problems in Elementary Particles*, ed., G. Puppi, Academic Press, New York (1968). See also the briefer reviews by P. G. H. Sandars, *Contemporary Physics* **7**, 419 (1966) and R. H. Carrigan, *Nuovo Cimento* **38**, 638 (1965).

There are some necessary preliminaries before examining Dirac's argument. One question that arises is whether or not it is possible to tell that particles have magnetic as well as electric charge. Let us suppose that there exist magnetic charge and current densities, ρ_m and \mathbf{J}_m , in addition to the electric densities, ρ_e and \mathbf{J}_e . The Maxwell equations would then be

$$\begin{aligned}\nabla \cdot \mathbf{D} &= 4\pi\rho_e, & \nabla \times \mathbf{H} &= \frac{1}{c} \frac{\partial \mathbf{D}}{\partial t} + \frac{4\pi}{c} \mathbf{J}_e \\ \nabla \cdot \mathbf{B} &= 4\pi\rho_m, & -\nabla \times \mathbf{E} &= \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} + \frac{4\pi}{c} \mathbf{J}_m\end{aligned}\quad (6.150)$$

The magnetic densities are assumed to satisfy the same form of the continuity equation as the electric densities. It appears from these equations that the existence of magnetic charge and current would have observable electromagnetic consequences. Consider, however, the following *duality transformation*:

$$\begin{aligned}\mathbf{E} &= \mathbf{E}' \cos \xi + \mathbf{H}' \sin \xi, & \mathbf{D} &= \mathbf{D}' \cos \xi + \mathbf{B}' \sin \xi \\ \mathbf{H} &= -\mathbf{E}' \sin \xi + \mathbf{H}' \cos \xi, & \mathbf{B} &= -\mathbf{D}' \sin \xi + \mathbf{B}' \cos \xi\end{aligned}\quad (6.151)$$

For a real angle ξ , such a transformation leaves quadratic forms such as $\mathbf{E} \times \mathbf{H}$, $(\mathbf{E} \cdot \mathbf{D} + \mathbf{B} \cdot \mathbf{H})$, and the components of the Maxwell stress tensor $T_{\alpha\beta}$ invariant. If the sources are transformed in the same way,

$$\begin{aligned}\rho_e &= \rho'_e \cos \xi + \rho'_m \sin \xi, & \mathbf{J}_e &= \mathbf{J}'_e \cos \xi + \mathbf{J}'_m \sin \xi \\ \rho_m &= -\rho'_e \sin \xi + \rho'_m \cos \xi, & \mathbf{J}_m &= -\mathbf{J}'_e \sin \xi + \mathbf{J}'_m \cos \xi\end{aligned}\quad (6.152)$$

then it is straightforward algebra to show that the generalized Maxwell equations (6.150) are invariant, that is, the equations for the primed fields (\mathbf{E}' , \mathbf{D}' , \mathbf{B}' , \mathbf{H}') are the same as (6.150) with the primed sources present.

The invariance of the equations of electrodynamics under duality transformations shows that it is a matter of convention to speak of a particle possessing an electric charge, but not magnetic charge. The only meaningful question is whether or not *all* particles have the same ratio of magnetic to electric charge. If they do, then we can make a duality transformation, choosing the angle ξ so that $\rho_m = 0$, $\mathbf{J}_m = 0$. We then have the Maxwell equations as they are usually known.

If, by convention, we choose the electric and magnetic charges of an electron to be $q_e = -e$, $q_m = 0$, then it is known that for a proton, $q_e = +e$ (with the present limits of error being $|q_e(\text{electron}) + q_e(\text{proton})|/e \sim 10^{-20}$ and $|q_m(\text{nucleon})| < 2 \times 10^{-24}e$).

This extremely small limit on the magnetic charge of a proton or neutron follows directly from knowing that the average magnetic field at the surface of the earth is not more than 1 gauss. The conclusion, to a very high degree of precision, is that the particles of ordinary matter possess only electric charge or, equivalently, they all have the same ratio of magnetic to electric charge. For

other, unstable, particles the question of magnetic charge is more open, but no positive evidence exists.

The transformation properties of ρ_m and \mathbf{J}_m under rotations, spatial inversion, and time reversal are important. From the known behavior of \mathbf{E} and \mathbf{B} in the usual formulation we deduce from the second line in (6.150) that

ρ_m is a pseudoscalar density, odd under time reversal
and \mathbf{J}_m is a pseudovector density, even under time reversal.

Since the symmetries of ρ_m under both spatial inversion and time reversal are opposite to those of ρ_e , it is a necessary consequence of the existence of a particle with both electric and magnetic charges that space inversion and time reversal are no longer valid symmetries of the laws of physics. It is a fact, of course, that these symmetry principles are not exactly valid in the realm of elementary particle physics, but present evidence is that their violation is extremely small and associated somehow with the weak interactions. Future developments may link electromagnetic, weak, and perhaps strong, interactions and utilize particles carrying magnetic charge as the vehicle for violation of space inversion and time reversal symmetries. With no evidence for monopoles, this remains speculation.

In spite of the negative evidence for the existence of magnetic monopoles, let us turn to Dirac's ingenious proposal. By considering the quantum mechanics of an electron in the presence of a magnetic monopole, he showed that consistency required the quantization condition,

$$\frac{ge}{\hbar c} = \frac{n}{2}, \quad n = 0, \pm 1, \pm 2, \dots \quad (6.153)$$

where e is the electronic charge, \hbar is Planck's constant over 2π , and g is the magnetic charge of the monopole. The discrete nature of electric charge thus follows from the existence of a monopole. The magnitude of e is not determined, except in terms of the magnetic charge g . The argument can be reversed. With the known value of the fine structure constant $e^2/\hbar c = \frac{1}{137}$, we infer the existence of magnetic monopoles with charges g whose magnetic "fine structure" constant is

$$\frac{g^2}{\hbar c} = \frac{n^2}{4} \left(\frac{\hbar c}{e^2} \right) \approx \frac{137}{4} n^2$$

Such monopoles are known as *Dirac monopoles*. Their coupling strength is enormous, making their extraction from matter with d.c. magnetic fields and their subsequent detection very simple in principle. For instance, the energy loss in matter by a relativistic Dirac monopole is approximately the same as that of a relativistic heavy nucleus with $Z = 137n/2$. It can presumably be distinguished from such a nucleus if it is brought to rest because it will not show an increase in ionization at the end of its range (see Problem 13.8).

6.13 Discussion of the Dirac Quantization Condition

Semiclassical considerations can illuminate the Dirac quantization condition (6.153). First, we consider the deflection at large impact parameters of a particle of charge e and mass m by the field of a stationary magnetic monopole of magnetic charge g . At sufficiently large impact parameter, the change in the state of motion of the charged particle can be determined by computing the impulse of the force, assuming the particle is undeflected. The geometry is shown in Fig. 6.8. The particle is incident parallel to the z axis with an impact parameter b and a speed v and is acted on by the radially directed magnetic field of the monopole, $\mathbf{B} = g\mathbf{r}/r^3$, according to the Lorentz force (6.113). In the approximation that the particle is undeflected, the only force acting throughout the collision is a y component,

$$F_y = \frac{ev}{c} B_x = \frac{eg}{c} \frac{vb}{(b^2 + v^2 t^2)^{3/2}} \quad (6.154)$$

The impulse transmitted by this force is

$$\Delta p_y = \frac{egvb}{c} \int_{-\infty}^{\infty} \frac{dt}{(b^2 + v^2 t^2)^{3/2}} = \frac{2eg}{cb} \quad (6.155)$$

Since the impulse is in the y direction, the particle is deflected out of the plane of Fig. 6.8, that is, in the azimuthal direction. Evidently the particle's angular momentum is changed by the collision, a result that is not surprising in the light of the noncentral nature of the force. The magnitude of the change in angular momentum is somewhat surprising, however. There is no z component of \mathbf{L}

Fig. 6.8 Charged particle passing a magnetic monopole at large impact parameter.

initially, but there is finally. The change in L_z is

$$\Delta L_z = b \Delta p_y = \frac{2eg}{c} \quad (6.156)$$

The change in the z component of angular momentum of the particle is independent of the impact parameter b and the speed v of the charged particle. It only depends on the product eg and the velocity of light, and is a universal value for a charged particle passing a stationary monopole, no matter how far away. If we assume that any change of angular momentum must occur in integral multiples of \hbar , we are led immediately to the Dirac quantization condition (6.153).*

The peculiarly universal character of the change in the angular momentum (6.156) of a charged particle in passing a magnetic monopole can be understood by considering the angular momentum contained in the fields of a point electric charge in the presence of a point magnetic monopole. If the monopole g is at $\mathbf{x} = \mathbf{R}_m$ and the charge e is at $\mathbf{x} = \mathbf{R}_e$, the magnetic and electric fields in all of space are

$$\mathbf{B} = g \frac{(\mathbf{x} - \mathbf{R}_m)}{|\mathbf{x} - \mathbf{R}_m|^3}, \quad \mathbf{E} = e \frac{(\mathbf{x} - \mathbf{R}_e)}{|\mathbf{x} - \mathbf{R}_e|^3} \quad (6.157)$$

The angular momentum \mathbf{L}_{em} is given by the volume integral of $\mathbf{x} \times \mathbf{g}$, where \mathbf{g} is the electromagnetic momentum density (6.118). Thus

$$\mathbf{L}_{em} = \frac{1}{4\pi c} \int \mathbf{x} \times (\mathbf{E} \times \mathbf{B}) d^3x \quad (6.158)$$

It is physically plausible and mathematically verifiable that the total *momentum* of the fields (volume integral of \mathbf{g}) vanishes. This means that \mathbf{L}_{em} is independent of the choice of origin. It is then convenient to choose coordinates so that the magnetic and electric charges are located symmetrically about the origin on the z axis, as shown in Fig. 6.9. With a choice of cylindrical coordinates for the integration, the angular momentum is given explicitly by

$$\mathbf{L}_{em} = \frac{ega}{2\pi c} \int_{-\infty}^{\infty} dz \int_0^{\infty} \rho d\rho \int_0^{2\pi} d\phi \frac{[\rho^2 \mathbf{e}_3 - \rho z (\cos \phi \mathbf{e}_1 + \sin \phi \mathbf{e}_2)]}{[(\rho^2 + z^2 + a^2)^2 - 4a^2 z^2]^{3/2}}$$

where the separation of the two charges is $2a$. Upon integration over azimuth, the x and y components vanish, leaving

$$\mathbf{L}_{em} = \mathbf{e}_3 \frac{ega}{c} \int_{-\infty}^{\infty} dz \int_0^{\infty} \frac{\rho^3 d\rho}{[(\rho^2 + z^2 + a^2)^2 - 4a^2 z^2]^{3/2}}$$

* This argument is essentially due to A. S. Goldhaber, *Phys. Rev.* **140**, B1407 (1965).

Fig. 6.9

With the introduction of dimensionless variables $s = \rho/a$, $t = z/a$, this becomes

$$\mathbf{L}_{em} = \left(\frac{eg}{c}\right) \mathbf{e}_3 \int_{-\infty}^{\infty} dt \int_0^{\infty} \frac{s^3 ds}{[(s^2 + t^2 + 1)^2 - 4t^2]^{3/2}}$$

The electromagnetic angular momentum is thus independent of the distance of separation of the magnetic and electric charges. Its magnitude is a pure number times eg/c . The double integral can be evaluated in a straightforward manner; its value is unity. The field angular momentum is therefore*

$$\mathbf{L}_{em} = \frac{eg}{c} \mathbf{e}_3 \quad (6.159)$$

It is directed along the line from the electric to the magnetic charge and has magnitude equal to the product of the charges (in Gaussian units) divided by the velocity of light. If we now think of the collision process of Fig. 6.8 and the total angular momentum of the system, that is, the sum of the particle's and the electromagnetic field's, we see that the total angular momentum is conserved. The change (6.156) in the angular momentum of the particle is just balanced by the change in the electromagnetic angular momentum (6.159) caused by the

* This result was first stated by J. J. Thomson, *Elements of the Mathematical Theory of Electricity and Magnetism*, Cambridge University Press, Section 284 of the third (1904) and subsequent editions. The argument of Section 284 is exactly the converse of ours. From the conservation of angular momentum Thomson deduces the magnetic part $e(\mathbf{v} \times \mathbf{B})/c$ of the Lorentz force.

reversal of the direction \mathbf{R} . A systematic discussion of the classical and quantum-mechanical scattering problem, including the electromagnetic angular momentum, is given by Goldhaber (*loc. cit.*).

The Thomson result (6.159) was used by Saha* and independently by Wilson† to derive the Dirac condition (6.153) by semiclassical means. In order to get $n/2$ instead of n when only the field angular momentum is considered, it is necessary to postulate half-integral quantization of \mathbf{L}_{em} , a somewhat undesirable hypothesis for the electromagnetic field.

Finally, we present a simplified discussion of Dirac's original (1931) argument leading to (6.153). In discussing the quantum mechanics of an electron in the presence of a magnetic monopole it is desirable to change as little as possible of the formalism of electromagnetic interactions, and keep, for example, the interaction Hamiltonian in the standard form,

$$H_{int} = e\Phi - \frac{e}{mc} \mathbf{p} \cdot \mathbf{A}$$

where Φ and \mathbf{A} are the scalar and vector potentials of the external sources. To do this with a magnetic charge it is necessary to employ an artifice. The magnetic charge g is imagined to be the end of a line of dipoles or a tightly wound solenoid that stretches off to infinity, as shown in Fig. 6.10. The monopole and its

Fig. 6.10 Two representations of a magnetic monopole g , one as the termination of a line of dipoles and the other as the end of a tightly wound solenoid, both “strings” stretching off to infinity.

* M. N. Saha, *Ind. J. Phys.* **10**, 141 (1936); *Phys. Rev.* **75**, 1968 (1949).

† H. A. Wilson, *Phys. Rev.* **75**, 309 (1949).

attached string, as the line of dipoles or solenoid is called, can then be treated more or less normally within the framework of conventional electromagnetic interactions where $\mathbf{B} = \nabla \times \mathbf{A}$, etc. From (5.55) we see that the elemental vector potential $d\mathbf{A}$ for a magnetic dipole element $d\mathbf{m}$ at \mathbf{x}' is

$$d\mathbf{A}(\mathbf{x}) = -d\mathbf{m} \times \nabla \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) \quad (6.160)$$

Thus for a string of dipoles or solenoid whose location is given by the string L the vector potential is

$$\mathbf{A}_L(\mathbf{x}) = -g \int_L d\mathbf{l} \times \nabla \left(\frac{1}{|\mathbf{x} - \mathbf{x}'|} \right) \quad (6.161)$$

For all points except on the string, this vector potential has a curl that is directed radially outwards from the end of the string, varies inversely with distance squared, with total outward flux $4\pi g$, as expected for the \mathbf{B} field of monopole g . On the string itself the vector potential is singular. This singular behavior is equivalent to an intense field \mathbf{B}' inside the solenoid and bringing a return contribution of flux $(-4\pi g)$ in along the string to cancel the pole's outward flow. So far we have just described a long thin solenoid. To exhibit the field of the monopole alone we write

$$\mathbf{B}_{\text{monopole}} = \nabla \times \mathbf{A} - \mathbf{B}'$$

where \mathbf{B}' exists only on the string (inside the solenoid). Dirac now argued that in order to describe the interaction of the electron with a magnetic *monopole*, rather than with a long thin solenoid, it is mandatory that the electron never "see" the singular field \mathbf{B}' . He thus required the electronic wave function to vanish along the string. This arbitrary postulate has been criticized, but discussion of such aspects leads us too far afield and is not central to our limited purpose. Dirac's later work (1948) treats the question of the unobservability of the strings in detail.

If (6.161) for $\mathbf{A}_L(\mathbf{x})$ is accepted as the appropriate vector potential for a monopole and its string L , there remains the problem of the arbitrariness of the location of the string. Clearly, the physical observables should not depend on where the string is. We now show that a choice of different string positions is equivalent to different choices of gauge for the vector potential. Indeed, the requirements of gauge invariance of the Schrödinger equation and single-valuedness of the wave function lead to the Dirac quantization condition (6.153). Consider two different strings L and L' , as shown in Fig. 6.11. The difference of the two vector potentials is given by (6.161) with the integral taken along the closed path $C = L' - L$ around the area S . By Problem 5.1, p. 205, this

Fig. 6.11 Two different strings L and L' give monopole vector potentials differing by a gauge transformation involving the gradient of the solid angle $\Omega_C(\mathbf{x})$ subtended at the observation point P by the surface S spanning the contour $C = L' - L$.

can be written

$$\mathbf{A}_{L'}(\mathbf{x}) = \mathbf{A}_L(\mathbf{x}) + g \nabla \Omega_C(\mathbf{x}) \quad (6.162)$$

where Ω_C is the solid angle subtended by the contour C at the observation point \mathbf{x} . Comparison with the gauge transformation equations, $\mathbf{A} \rightarrow \mathbf{A}' = \mathbf{A} + \nabla \chi$, $\Phi \rightarrow \Phi' = \Phi - (1/c)(\partial \chi / \partial t)$, shows that a change in string from L to L' is equivalent to a gauge transformation, $\chi = g \Omega_C$.

It is well known in quantum mechanics* that a change in the gauge of the electromagnetic potentials leaves the form of the Schrödinger equation invariant provided that the wave function is transformed according to

$$\psi \rightarrow \psi' = \psi e^{i\chi/\hbar c}$$

where e is the charge of the particle and χ is the gauge function. A change in the location of the string from L to L' must therefore be accompanied by a modification of the phase of the wave function of the electron,

$$\psi \rightarrow \psi' = \psi e^{i(eg/\hbar c)\Omega_C} \quad (6.163)$$

Since Ω_C changes suddenly by 4π as the electron crosses the surface S , the wave

* The demonstration is very easy. See, for example, H. A. Kramers, *Quantum Mechanics*, North-Holland, Amsterdam, (1957), Dover reprint (1964), Section 62.

function will be multiple-valued unless we require

$$\frac{eg}{\hbar c} \cdot 4\pi = 2\pi n, \quad n = 0, \pm 1, \pm 2, \dots$$

This is the Dirac quantization condition (6.153). It follows from the general requirements of gauge invariance and single-valuedness of the wave function, independent of the location of the monopole's string.

The above discussion of magnetic monopoles presents only the most basic concepts. An extensive literature exists on modifications of the quantization condition, attempts at a quantum electrodynamics with magnetic monopoles and electric charges, and other aspects. The interested reader can pursue the subject through the article by Amaldi (*op. cit.*) and the references at the end of the chapter.

The mathematical topics in this chapter center around the wave equation. The initial-value problem in one, two, three, and more dimensions is discussed by

Morse and Feshbach, pp. 843-847,

and, in more mathematical detail, by

Hadamard.

PROBLEMS

6.1 (a) Show that for a system of current-carrying elements in empty space the total energy in the magnetic field is

$$W = \frac{1}{2c^2} \int d^3x' \int \frac{\mathbf{J}(\mathbf{x}) \cdot \mathbf{J}(\mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|}$$

where $\mathbf{J}(\mathbf{x})$ is the current density.

(b) If the current configuration consists of n circuits carrying currents I_1, I_2, \dots, I_n , show that the energy can be expressed as

$$W = \frac{1}{2} \sum_{i=1}^n L_i I_i^2 + \sum_{i=1}^n \sum_{j>i}^n M_{ij} I_i I_j$$

Exhibit integral expressions for the self-inductances (L_i) and the mutual inductances (M_{ij}).

6.2 A two-wire transmission line consists of a pair of nonpermeable parallel wires of radii a and b separated by a distance $d > a + b$. A current flows down one wire and back

the other. It is uniformly distributed over the cross section of each wire. Show that the self-inductance per unit length is

$$c^2 L = 1 + 2 \ln \left(\frac{d^2}{ab} \right)$$

- 6.3 A circuit consists of a long thin conducting shell of radius a and a parallel return wire of radius b on axis inside. If the current is assumed distributed uniformly throughout the cross section of the wire, calculate the self-inductance per unit length. What is the self-inductance if the inner conductor is a thin hollow tube?

- 6.4 Show that the mutual inductance of two circular coaxial loops in a homogeneous medium of permeability μ is

$$M_{12} = \frac{4\pi\mu}{c^2} \sqrt{ab} \left[\left(\frac{2}{k} - k \right) K(k) - \frac{2}{k} E(k) \right]$$

where

$$k^2 = \frac{4ab}{(a+b)^2 + d^2}$$

and a , b are the radii of the loops, d is the distance between their centers, and K and E are the complete elliptic integrals.

Find the limiting value when $d \ll a$, b and $a = b$.

- 6.5 A transmission line consists of two, parallel *perfect* conductors of arbitrary, but constant, cross section. Current flows down one conductor and returns via the other.

Problem 6.5

Show that the product of the inductance per unit length L and the capacitance per unit length C is

$$LC = \frac{\mu\epsilon}{c^2}$$

where μ and ϵ are the permeability and the dielectric constant of the medium surrounding the conductors, while c is the velocity of light *in vacuo*. (See the discussion about magnetic fields near perfect conductors at the beginning of Section 5.13.)

- 6.6 Consider two current loops (as in Fig. 5.3, p. 172) whose orientation in space is fixed, but whose relative separation can be changed. Let 0_1 and 0_2 be origins in the two loops, fixed relative to each loop, and \mathbf{x}_1 and \mathbf{x}_2 be coordinates of elements $d\mathbf{l}_1$ and $d\mathbf{l}_2$, respectively, of the loops referred to the respective origins. Let \mathbf{R} be the relative coordinate of the origins, directed from loop #2 to loop #1.

(a) Starting from the expression (5.10) for the force between the loops, show that it can be written

$$\mathbf{F}_{12} = I_1 I_2 \nabla_{\mathbf{R}} M_{12}(\mathbf{R})$$

where M_{12} is the mutual inductance of the loops,

$$M_{12}(\mathbf{R}) = \frac{1}{c^2} \oint \oint \frac{d\mathbf{l}_1 \cdot d\mathbf{l}_2}{|\mathbf{x}_1 - \mathbf{x}_2 + \mathbf{R}|}$$

and it is assumed that the orientation of the loops does not change with \mathbf{R} .

(b) Show that the mutual inductance, viewed as a function of \mathbf{R} , is a solution of the Laplace equation,

$$\nabla_{\mathbf{R}}^2 M_{12}(\mathbf{R}) = 0$$

The importance of this result is that the uniqueness of solutions of the Laplace equation allows the exploitation of the properties of such solutions, provided a solution can be found for a particular value of \mathbf{R} .

6.7 Two identical circular loops of radius a are initially located a distance R apart on a common axis perpendicular to their planes.

(a) From the expression $W_{12} = (1/c) \int d^3x \mathbf{J}_1 \cdot \mathbf{A}_2$ and the result for \mathbf{A}_Φ from Problem 5.4(b), show that the mutual inductance of the loops is

$$M_{12} = \frac{4\pi^2 a^2}{c^2} \int_0^\infty dk e^{-kR} J_1^2(ka)$$

(b) Show that for $R > 2a$, M_{12} has the expansion,

$$M_{12} = \frac{2\pi^2 a^2}{c^2} \left[\left(\frac{a}{R} \right)^3 - 3 \left(\frac{a}{R} \right)^5 + \frac{75}{8} \left(\frac{a}{R} \right)^7 + \cdots \right]$$

(c) Use the techniques of Section 3.3 for solutions of the Laplace equation to show that the mutual inductance for two coplanar identical circular loops of radius a whose centers are separated by a distance $R > 2a$ is

$$M_{12} = -\frac{\pi^2 a^2}{c^2} \left[\left(\frac{a}{R} \right)^3 + \frac{9}{4} \left(\frac{a}{R} \right)^5 + \frac{375}{64} \left(\frac{a}{R} \right)^7 + \cdots \right]$$

(d) Calculate the forces between the loops in the common axis and coplanar configurations. Relate the answers to those of Problem 5.10.

6.8 The microscopic current $\mathbf{j}(\mathbf{x}, t)$ can be written as

$$\mathbf{j}(\mathbf{x}, t) = \sum_i q_i \mathbf{v}_i \delta(\mathbf{x} - \mathbf{x}_i(t))$$

where the point charge q_i is located at the point $\mathbf{x}_i(t)$ and has velocity $\mathbf{v}_i = d\mathbf{x}_i(t)/dt$. Just as for the charge density, this current can be broken up into a “free” (conduction) electron contribution and a bound (molecular) current contribution.

Following the averaging procedures of Section 6.7 and assuming *nonrelativistic* addition of velocities, consider the averaged current, $\langle \mathbf{j}(\mathbf{x}, t) \rangle$.

(a) Show that the averaged current can be written in the form of (6.96) with the definitions (6.92), (6.97), and (6.98).

(b) Show that for a medium whose internal molecular velocities can be neglected, but which is in bulk motion (i.e., $\mathbf{v}_n = \mathbf{v}$ for all n),

$$\mathbf{B} - \mathbf{H} = 4\pi\mathbf{M} + (\mathbf{D} - \mathbf{E}) \times \frac{\mathbf{v}}{c}$$

This shows that a moving polarization (\mathbf{P}) produces an effective magnetization density. *Hints for (a):* Consider quantities like $(d\mathbf{p}_n/dt)$, $(dQ_{ab}^{(n)}/dt)$ and see what they look like. Also note that

$$\frac{d}{dt}(\mathbf{x} - \mathbf{x}_n(t)) = -\mathbf{v}_n \cdot \nabla f(\mathbf{x} - \mathbf{x}_n(t))$$

- 6.9 A dielectric sphere of dielectric constant ϵ and radius a is located at the origin. There is a uniform applied electric field E_0 in the x direction. The sphere rotates with an angular velocity ω about the z axis. Show that there is a magnetic field $\mathbf{H} = -\nabla\Phi_M$, where

$$\Phi_M = \frac{3}{5} \left(\frac{\epsilon - 1}{\epsilon + 2} \right) E_0 \frac{\omega}{c} \left(\frac{a}{r_{>}} \right)^5 \cdot xz$$

where $r_{>}$ is the larger of r and a . The motion is nonrelativistic.

You may use the results of Section 4.4 for the dielectric sphere in an applied field.

- 6.10 Discuss the conservation of energy and linear momentum for a macroscopic system of sources and electromagnetic fields in a uniform, isotropic medium described by a dielectric constant ϵ and a permeability μ . Show that in a straightforward calculation the energy density, Poynting vector, field-momentum density, and Maxwell stress tensor are given by the Minkowski expressions,

$$u = \frac{1}{8\pi} (\epsilon E^2 + \mu H^2)$$

$$\mathbf{S} = \frac{c}{4\pi} (\mathbf{E} \times \mathbf{H})$$

$$\mathbf{g} = \frac{\mu\epsilon}{4\pi c} (\mathbf{E} \times \mathbf{H})$$

$$T_{ij} = \frac{1}{4\pi} [\epsilon E_i E_j + \mu H_i H_j - \frac{1}{2} \delta_{ij} (\epsilon E^2 + \mu H^2)]$$

What modifications arise if ϵ and μ are functions of position?

- 6.11 With the same assumptions as in Problem 6.10 discuss the conservation of angular momentum. Show that the differential and integral forms of the conservation law are

$$\frac{\partial}{\partial t} (\mathcal{L}_{\text{mech}} + \mathcal{L}_{\text{field}}) + \nabla \cdot \vec{\mathbf{M}} = 0$$

and

$$\frac{d}{dt} \int_V (\mathcal{L}_{\text{mech}} + \mathcal{L}_{\text{field}}) d^3x + \int_S \mathbf{n} \cdot \vec{\mathbf{M}} da = 0$$

where the field angular-momentum density is

$$\mathcal{L}_{\text{field}} = \mathbf{x} \times \mathbf{g} = \frac{\mu\epsilon}{4\pi c} \mathbf{x} \times (\mathbf{E} \times \mathbf{H})$$

and the flux of angular momentum is described by the tensor

$$\vec{\mathbf{M}} = \vec{\mathbf{T}} \times \mathbf{x}$$

Note: Here we have used the dyadic notation for M_{ij} and T_{ij} . The double-headed arrow conveys a fairly obvious meaning. For example, $\mathbf{n} \cdot \vec{\mathbf{M}}$ is a vector whose j th component is $\sum_i n_i M_{ij}$. The second-rank $\vec{\mathbf{M}}$ can be written as a third-rank tensor, $M_{ijk} = T_{ij}x_k - T_{ik}x_j$. But in the indices j and k it is antisymmetric and so has only three independent elements. Including the index i , M_{ijk} therefore has nine components and can be written as a pseudo tensor of the second rank, as above.

6.12 A transverse plane wave is incident normally in vacuum on a perfectly absorbing flat screen.

(a) From the law of conservation of linear momentum show that the pressure (called radiation pressure) exerted on the screen is equal to the field energy per unit volume in the wave.

(b) In the neighborhood of the earth the flux of electromagnetic energy from the sun is approximately 0.14 watt/cm^2 . If an interplanetary "sailplane" had a sail of mass 10^{-4} gm/cm^2 of area and negligible other weight, what would be its maximum acceleration in centimeters per second squared due to the solar radiation pressure? How does this compare with the acceleration due to the solar "wind" (corpuscular radiation)?

6.13 Consider the definition of the admittance $Y = G - iB$ of a two-terminal linear passive network in terms of field quantities by means of the complex Poynting theorem of Section 6.10.

(a) By considering the complex conjugate of (6.134) obtain general expressions for the conductance G and susceptance B for the general case including radiation loss.

(b) Show that at low frequencies the expressions equivalent to (6.139) and (6.140) are

$$G \approx \frac{1}{|\mathbf{V}_i|^2} \int_V \sigma |\mathbf{E}|^2 d^3x$$

$$B \approx -\frac{4\omega}{|\mathbf{V}_i|^2} \int_V (w_m - w_e) d^3x$$

6.14 A parallel plate capacitor is formed of two flat rectangular perfectly conducting sheets of dimensions a and b separated by a distance d small compared to a or b . Current is fed in and taken out uniformly along the adjacent edges of length b . With the input current and voltage defined at this end of the capacitor, calculate the input impedance or admittance using the field concepts of Section 6.10.

(a) Calculate the electric and magnetic fields in the capacitor correct to second order in powers of the frequency, but neglecting fringing fields.

(b) Show that the expansion of the reactance (6.140) in powers of the frequency to an appropriate order is the same as that obtained for a lumped circuit consisting of a capacitance $C = ab/4\pi d$ in series with an inductance $L = 4\pi ad/3bc^2$, where c is the velocity of light.

6.15 An ideal circular parallel plate capacitor of radius a and plate separation $d \ll a$ is connected to a current source by axial leads, as shown in the sketch. The current in the wire is $I(t) = I_0 \cos \omega t$.

Problem 6.15

(a) Calculate the electric and magnetic fields between the plates to second order in powers of the frequency (or wave number), neglecting the effects of fringing fields.

(b) Calculate the volume integrals of w_e and w_m that enter the definition of the reactance X , (6.140), to second order in ω . Show that in terms of the input current I_i , defined by $I_i = -i\omega Q$, where Q is the total charge on one plate, these energies are

$$\int w_e d^3x = \frac{|I_i|^2 d}{\omega^2 a^2}, \quad \int w_m d^3x = \frac{|I_i|^2 d}{8c^2} \left(1 + \frac{\omega^2 a^2}{12c^2}\right)$$

(c) Show that the equivalent series circuit has $C \approx a^2/4d$, $L \approx d/2c^2$, and that an estimate for the resonant frequency of the system is $\omega_{res} \approx 2\sqrt{2} c/a$. Compare with the first root of $J_0(x)$.

6.16 If a conductor or semiconductor has current flowing in it because of an applied electric field, and a transverse magnetic field is applied, there develops a component of electric field in the direction orthogonal to both the applied electric field (direction of current flow) and the magnetic field, resulting in a voltage difference between the sides of the conductor. This phenomenon is known as the *Hall effect*.

(a) Use the known properties of electromagnetic fields under rotations and spatial reflections and the assumption of Taylor series expansions around zero magnetic field strength to show that for an isotropic medium the generalization of Ohm's law, correct to second order in the magnetic field, must have the form,

$$\mathbf{E} = \rho_0 \mathbf{J} + R(\mathbf{H} \times \mathbf{J}) + \beta_1 H^2 \mathbf{J} + \beta_2 (\mathbf{H} \cdot \mathbf{J}) \mathbf{H}$$

where ρ_0 is the resistivity in the absence of the magnetic field and R is called the Hall coefficient.

(b) What about the requirements of time-reversal invariance?

6.17 (a) Calculate the force in dynes acting on a Dirac monopole of the minimum magnetic charge located a distance 0.5 angstroms from and in the median plane of a magnetic dipole with dipole moment equal to one nuclear magneton ($e\hbar/2m_p c$).

(b) Compare the force in (a) with atomic forces such as the direct electrostatic force between charges (at the same separation), the spin-orbit force, the hyperfine interaction. Comment on the question of binding of magnetic monopoles to nuclei with magnetic moments. Assume that the monopole mass is at least that of a proton.

Ref: D. Sivers, *Phys. Rev. D* **2**, 2048 (1970).

6.18 Consider the Dirac expression

$$\mathbf{A}(\mathbf{x}) = g \int_L \frac{d\mathbf{l}' \times (\mathbf{x} - \mathbf{x}')}{|\mathbf{x} - \mathbf{x}'|^3}$$

for the vector potential of a magnetic monopole and its associated string L . Suppose for definiteness that the monopole is located at the origin and the string along the negative z axis.

(a) Calculate \mathbf{A} explicitly and show that in spherical coordinates it has components

$$A_r = 0, \quad A_\theta = 0, \quad \text{and} \quad A_\phi = \frac{g(1 - \cos \theta)}{r \sin \theta} = (g/r) \tan(\theta/2)$$

(b) Verify that $\mathbf{B} = \nabla \times \mathbf{A}$ is the Coulomb-like field of a point charge, except perhaps at $\theta = \pi$.

(c) With the \mathbf{B} determined in part (b), evaluate the total magnetic flux passing through the circular loop of radius $R \sin \theta$ shown in the figure below. Consider $\theta < \pi/2$ and $\theta > \pi/2$ separately, but always calculate the upwards flux.

(d) From $\oint \mathbf{A} \cdot d\mathbf{l}$ around the loop, determine the total magnetic flux through the loop. Compare the result with that found in part (c). Show that they are equal for $0 < \theta < \pi/2$, but have a constant difference for $\pi/2 < \theta < \pi$. Interpret this difference.

Problem 6.18

6.19 An example of the preservation of causality and finite speed of propagation in spite of the use of the Coulomb gauge is afforded by a dipole source that is flashed on and off at $t=0$. The effective charge and current densities are

$$\rho(\mathbf{x}, t) = \delta(x)\delta(y)\delta'(z)\delta(t)$$

$$J_z(\mathbf{x}, t) = -\delta(x)\delta(y)\delta(z)\delta'(t)$$

where a prime means differentiation with respect to the argument. This dipole is of unit strength and it points in the negative z -direction.

(a) Show that the instantaneous Coulomb potential (6.45) is

$$\Phi(\mathbf{x}, t) = -\delta(t) \frac{z}{r^3}$$

(b) Show that the transverse current \mathbf{J}_t is

$$\mathbf{J}_t(\mathbf{x}, t) = -\delta'(t) \left[\frac{2}{3} \boldsymbol{\epsilon}_3 \delta(\mathbf{x}) - \frac{\boldsymbol{\epsilon}_3}{4\pi r^3} + \frac{3}{4\pi r^3} \mathbf{n}(\boldsymbol{\epsilon}_3 \cdot \mathbf{n}) \right]$$

where the factor of 2/3 multiplying the delta function comes from treating the gradient of z/r^3 according to Eq. (4.20).

(c) Show that the electric and magnetic fields are causal and that the electric field components are

$$E_x(\mathbf{x}, t) = \frac{c}{r} \left[-\delta''(r-ct) + \frac{3}{r} \delta'(r-ct) - \frac{3}{r^2} \delta(r-ct) \right] \sin \theta \cos \theta \cos \phi$$

E_y is the same as E_x , with $\cos \phi$ replaced by $\sin \phi$, and

$$E_z(\mathbf{x}, t) = \frac{c}{r} \left[\sin^2 \theta \delta''(r-ct) + (3 \cos^2 \theta - 1) \cdot \left(\frac{\delta'(r-ct)}{r} - \frac{\delta(r-ct)}{r^2} \right) \right]$$

Hint: While the answer in (b) displays the transverse current explicitly, the less explicit form,

$$\mathbf{J}_t(\mathbf{x}, t) = -\delta'(t) \left[\boldsymbol{\epsilon}_3 \delta(\mathbf{x}) + \frac{1}{4\pi} \nabla \frac{\partial}{\partial z} \left(\frac{1}{r} \right) \right]$$

can be used with Eq. (6.69) to calculate the vector potential and the fields for part (c). An alternative method is to use the Fourier transforms in time of \mathbf{J}_t and \mathbf{A} , the Green function (6.62) and its spherical wave expansion from Chapter 16.

7

Plane Electromagnetic Waves and Wave Propagation

This chapter is concerned with plane waves in unbounded, or perhaps semiinfinite, media. The basic properties of plane electromagnetic waves in nonconducting media—their transverse nature, linear and circular polarization states—are treated first. Then the important Fresnel formulas for reflection and refraction at a plane interface are derived and applied. This is followed by a survey of the high-frequency dispersion properties of dielectrics, conductors, and plasmas. The richness of nature is illustrated with a panoramic view (Fig. 7.9) of the index of refraction and absorption coefficient of liquid water over 20 decades of frequency. Then comes a simplified discussion of propagation in the ionosphere, and of waves in a conducting or dissipative medium. The ideas of phase and group velocities and the spreading of a pulse or wave packet as it propagates in a dispersive medium come next. The important subject of causality and its consequences for the dispersive properties of a medium are discussed in some detail, including the Kramers–Kronig dispersion relations and various sum rules derived from them. The chapter concludes with a treatment of the classic problem of the arrival of a signal in a dispersive medium, first discussed by Sommerfeld and Brillouin (1914) but only recently subjected to experimental test.

7.1 Plane Waves in a Nonconducting Medium

A basic feature of the Maxwell equations for the electromagnetic field is the existence of traveling wave solutions which represent the transport of energy from one point to another. The simplest and most fundamental electromagnetic waves are transverse, plane waves. We proceed to see how such solutions can be obtained in simple nonconducting media described by spatially constant permeability and susceptibility. In the absence of sources, the Maxwell equations in an

infinite medium are:

$$\left. \begin{aligned} \nabla \cdot \mathbf{E} &= 0 & \nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} &= 0 \\ \nabla \cdot \mathbf{B} &= 0 & \nabla \times \mathbf{B} - \frac{\mu\epsilon}{c} \frac{\partial \mathbf{E}}{\partial t} &= 0 \end{aligned} \right\} \quad (7.1)$$

where the medium is characterized by the parameters μ , ϵ , assumed for the moment to be independent of frequency. By combining the two curl equations and making use of the vanishing divergences, we find easily that each cartesian component of \mathbf{E} and \mathbf{B} satisfies the wave equation:

$$\nabla^2 u - \frac{1}{v^2} \frac{\partial^2 u}{\partial t^2} = 0 \quad (7.2)$$

where

$$v = \frac{c}{\sqrt{\mu\epsilon}} \quad (7.3)$$

is a constant of the dimensions of velocity characteristic of the medium. The wave equation (7.2) has the well-known plane-wave solutions:

$$u = e^{i\mathbf{k} \cdot \mathbf{x} - i\omega t} \quad (7.4)$$

where the frequency ω and the magnitude of the wave vector \mathbf{k} are related by

$$k = \frac{\omega}{v} = \sqrt{\mu\epsilon} \frac{\omega}{c} \quad (7.5)$$

If we consider waves propagating in only one direction, say, the x direction, the fundamental solution is

$$u(x, t) = Ae^{ikx - i\omega t} + Be^{-ikx - i\omega t} \quad (7.6)$$

Using (7.5), this can be written

$$u_k(x, t) = Ae^{ik(x-vt)} + Be^{-ik(x+vt)}$$

If v is not a function of k (i.e., a nondispersive medium, with $\mu\epsilon$ independent of frequency), we know by the Fourier integral theorem (2.44) and (2.45) that by linear superposition we can construct from $u_k(x, t)$ a general solution of the form:

$$u(x, t) = f(x - vt) + g(x + vt) \quad (7.7)$$

where $f(z)$ and $g(z)$ are arbitrary functions. It is easy to verify directly that this is a solution of the wave equation (7.2). Equation (7.7) represents waves traveling to the right and to the left with velocities of propagation equal to v , which is called the *phase velocity* of the wave.

If the medium is dispersive, that is, if the product $\mu\epsilon$ is a function of frequency, some parts of the above discussion need modification. By making a Fourier

integral expansion in ω before combining the equations in (7.1), one is led to the Helmholtz wave equation,

$$\nabla^2 u + \mu\epsilon \frac{\omega^2}{c^2} u = 0 \quad (7.8)$$

Thus k is still given by (7.5). This means that for each frequency component the plane-wave solutions are (7.4). Only when we reconstitute the wave as a function of \mathbf{x} and t , does the dispersion produce modifications. Equation (7.7) no longer holds. The wave changes shape as it propagates (see Sections 7.8, 7.9, and 7.11).

The basic plane wave (7.4) and (7.5) satisfies the scalar-wave equation (7.8). But we still must consider the vector nature of the electromagnetic fields and the requirement of satisfying the Maxwell equations. With the convention that the physical electric and magnetic fields are obtained by taking the real parts of complex quantities, we assume that the plane-wave fields are of the form,

$$\begin{aligned} \mathbf{E}(\mathbf{x}, t) &= \mathcal{E} e^{i\mathbf{k}\cdot\mathbf{x} - i\omega t} \\ \mathbf{B}(\mathbf{x}, t) &= \mathcal{B} e^{i\mathbf{k}\cdot\mathbf{x} - i\omega t} \end{aligned} \quad (7.9)$$

where \mathcal{E} , \mathcal{B} , and \mathbf{n} are vectors that are constant in time and space. Each component of \mathbf{E} and \mathbf{B} satisfies the wave equation (7.8) provided

$$k^2 \mathbf{n} \cdot \mathbf{n} = \mu\epsilon \frac{\omega^2}{c^2}$$

To recover (7.5) it is necessary to assume that \mathbf{n} is a vector such that $\mathbf{n} \cdot \mathbf{n} = 1$. With the wave equation satisfied, there only remains the fixing of the vectorial properties so that (7.1) are valid. The divergence equations in (7.1) demand that

$$\mathbf{n} \cdot \mathcal{E} = 0 \quad \text{and} \quad \mathbf{n} \cdot \mathcal{B} = 0 \quad (7.10)$$

This means that \mathbf{E} and \mathbf{B} are both perpendicular to the direction of propagation \mathbf{n} . Such a wave is called a *transverse wave*. The curl equations provide a further restriction, namely

$$\mathcal{B} = \sqrt{\mu\epsilon} \mathbf{n} \times \mathcal{E} \quad (7.11)$$

If \mathbf{n} is real, (7.11) implies that \mathcal{E} and \mathcal{B} have the same phase. It is then useful to introduce a set of real mutually orthogonal unit vectors (\mathbf{e}_1 , \mathbf{e}_2 , \mathbf{n}), as shown in Fig. 7.1. In terms of these unit vectors the field strengths \mathcal{E} and \mathcal{B} are

$$\mathcal{E} = \epsilon_1 E_0, \quad \mathcal{B} = \epsilon_2 \sqrt{\mu\epsilon} E_0 \quad (7.12)$$

or

$$\mathcal{E} = \epsilon_2 E'_0, \quad \mathcal{B} = -\epsilon_1 \sqrt{\mu\epsilon} E'_0 \quad (7.12')$$

where E_0 and E'_0 are constants, possibly complex. The wave described by (7.9) and (7.12) or (7.12') is a transverse wave propagating in the direction \mathbf{n} . It

Fig. 7.1 Propagation vector \mathbf{k} and two orthogonal polarization vectors ϵ_1 and ϵ_2 .

represents a time-averaged flux of energy given by the real part of the complex Poynting vector:

$$\mathbf{S} = \frac{1}{2} \frac{c}{4\pi} \mathbf{E} \times \mathbf{H}^*$$

The energy flow (energy per unit area per unit time) is

$$\mathbf{S} = \frac{c}{8\pi} \sqrt{\frac{\epsilon}{\mu}} |E_0|^2 \mathbf{n} \quad (7.13)$$

The time-averaged density u is correspondingly

$$u = \frac{1}{16\pi} \left(\epsilon \mathbf{E} \cdot \mathbf{E}^* + \frac{1}{\mu} \mathbf{B} \cdot \mathbf{B}^* \right)$$

This gives

$$u = \frac{\epsilon}{8\pi} |E_0|^2 \quad (7.14)$$

The ratio of the magnitude of (7.13) to (7.14) shows that the speed of energy flow is $v = c/\sqrt{\mu\epsilon}$, as expected from (7.3).

In the discussion below (7.11) we assumed that \mathbf{n} was a real unit vector. This does not yield the most general possible solution for a plane wave. Suppose that \mathbf{n} is complex, and written as $\mathbf{n} = \mathbf{n}_R + i\mathbf{n}_I$. Then the exponential in (7.9) becomes

$$e^{i\mathbf{k}\mathbf{n}\cdot\mathbf{x} - i\omega t} = e^{-k\mathbf{n}_I\cdot\mathbf{x}} e^{i\mathbf{k}\mathbf{n}_R\cdot\mathbf{x} - i\omega t}$$

The wave possesses exponential growth or decay in some directions. It is then called an *inhomogeneous plane wave*. The surfaces of constant amplitude and constant phase are still planes, but they are no longer parallel. The relations (7.10) and (7.11) still hold. The requirement $\mathbf{n} \cdot \mathbf{n} = 1$ has real and imaginary

parts,*

$$\begin{aligned} n_R^2 - n_I^2 &= 1 \\ \mathbf{n}_R \cdot \mathbf{n}_I &= 0 \end{aligned} \quad (7.15)$$

The second of these conditions shows that \mathbf{n}_R and \mathbf{n}_I are orthogonal. The coordinate axes can be oriented so that \mathbf{n}_R is in the x direction and \mathbf{n}_I in the y direction. The first equation in (7.15) can be satisfied generally by writing

$$\mathbf{n} = \mathbf{e}_1 \cosh \theta + i\mathbf{e}_2 \sinh \theta \quad (7.16)$$

where θ is a real constant and \mathbf{e}_1 and \mathbf{e}_2 are real unit vectors in the x and y directions (not to be confused with \mathbf{e}_1 and \mathbf{e}_2). The most general vector \mathcal{E} satisfying $\mathbf{n} \cdot \mathcal{E} = 0$ is then

$$\mathcal{E} = (i\mathbf{e}_1 \sinh \theta - \mathbf{e}_2 \cosh \theta)A + \mathbf{e}_3 A' \quad (7.17)$$

where A and A' are complex constants. For $\theta \neq 0$, \mathcal{E} in general has components in the direction(s) of \mathbf{n} . It is easily verified that for $\theta = 0$, the solutions (7.12) and (7.12') are recovered.

We encounter simple examples of inhomogeneous plane waves in the discussion of total internal reflection and refraction in a conducting medium later in the chapter, although in the latter case the inhomogeneous nature arises from a complex wave number, not a complex unit vector \mathbf{n} . Inhomogeneous plane waves form a general basis for the treatment of boundary-value problems for waves and are especially useful in the solution of diffraction in two dimensions. The interested reader can refer to the book by *Clemmow* for an extensive treatment with examples.

7.2 Linear and Circular Polarization, Stokes Parameters

The plane wave (7.9) and (7.12) is a wave with its electric field vector always in the direction \mathbf{e}_1 . Such a wave is said to be linearly polarized with polarization vector \mathbf{e}_1 . Evidently the wave described by (7.12') is linearly polarized with polarization vector \mathbf{e}_2 and is linearly independent of the first. Thus the two waves,

$$\left. \begin{aligned} \mathbf{E}_1 &= \mathbf{e}_1 E_1 e^{i\mathbf{k} \cdot \mathbf{x} - i\omega t} \\ \mathbf{E}_2 &= \mathbf{e}_2 E_2 e^{i\mathbf{k} \cdot \mathbf{x} - i\omega t} \\ \mathbf{B}_j &= \sqrt{\mu\epsilon} \frac{\mathbf{k} \times \mathbf{E}_j}{k}, \quad j = 1, 2 \end{aligned} \right\} \quad (7.18)$$

with

* Note that if \mathbf{n} is complex it does not have unit magnitude, that is, $\mathbf{n} \cdot \mathbf{n} = 1$ does not imply $|\mathbf{n}|^2 = 1$.

can be combined to give the most general homogeneous plane wave propagating in the direction $\mathbf{k} = k\mathbf{n}$,

$$\mathbf{E}(\mathbf{x}, t) = (\epsilon_1 E_1 + \epsilon_2 E_2) e^{i\mathbf{k} \cdot \mathbf{x} - i\omega t} \quad (7.19)$$

The amplitudes E_1 and E_2 are complex numbers in order to allow the possibility of a phase difference between waves of different polarization.

If E_1 and E_2 have the same phase, (7.19) represents a *linearly polarized* wave, with its polarization vector making an angle $\theta = \tan^{-1}(E_2/E_1)$ with ϵ_1 and a magnitude $E = \sqrt{E_1^2 + E_2^2}$, as shown in Fig. 7.2.

If E_1 and E_2 have different phases, the wave (7.19) is *elliptically polarized*. To understand what this means let us consider the simplest case, *circular polarization*. Then E_1 and E_2 have the same magnitude, but differ in phase by 90° . The wave (7.19) becomes:

$$\mathbf{E}(\mathbf{x}, t) = E_0(\epsilon_1 \pm i\epsilon_2) e^{i\mathbf{k} \cdot \mathbf{x} - i\omega t} \quad (7.20)$$

with E_0 the common real amplitude. We imagine axes chosen so that the wave is propagating in the positive z direction, while ϵ_1 and ϵ_2 are in the x and y directions, respectively. Then the components of the actual electric field, obtained by taking the real part of (7.20), are

$$\left. \begin{aligned} E_x(\mathbf{x}, t) &= E_0 \cos(kz - \omega t) \\ E_y(\mathbf{x}, t) &= \mp E_0 \sin(kz - \omega t) \end{aligned} \right\} \quad (7.21)$$

At a *fixed point in space*, the fields (7.21) are such that the electric vector is constant in magnitude, but sweeps around in a circle at a frequency ω , as shown in Fig. 7.3. For the upper sign ($\epsilon_1 + i\epsilon_2$), the rotation is counter-clockwise when the observer is facing into the oncoming wave. This wave is called *left circularly polarized* in optics. In the terminology of modern physics, however, such a wave is said to have *positive helicity*. The latter description seems more appropriate because such a wave has a positive projection of angular momentum on the z axis (see Problem 7.21). For the lower sign ($\epsilon_1 - i\epsilon_2$), the rotation of \mathbf{E} is clockwise when looking into the wave; the wave is *right circularly polarized* (optics); it has *negative helicity*.

The two circularly polarized waves (7.20) form an equally acceptable set of basic fields for description of a general state of polarization. We introduce the

Fig. 7.2 Electric field of a linearly polarized wave.

Fig. 7.3 Electric field of a circularly polarized wave.

complex orthogonal unit vectors:

$$\epsilon_{\pm} = \frac{1}{\sqrt{2}}(\epsilon_1 \pm i\epsilon_2) \quad (7.22)$$

with properties

$$\left. \begin{aligned} \epsilon_{\pm}^* \cdot \epsilon_{\mp} &= 0 \\ \epsilon_{\pm}^* \cdot \epsilon_{\pm} &= 1 \end{aligned} \right\} \quad (7.23)$$

Then a general representation, equivalent to (7.19), is

$$\mathbf{E}(\mathbf{x}, t) = (E_+ \epsilon_+ + E_- \epsilon_-) e^{i\mathbf{k} \cdot \mathbf{x} - i\omega t} \quad (7.24)$$

where E_+ and E_- are complex amplitudes. If E_+ and E_- have different magnitudes, but the same phase, (7.24) represents an elliptically polarized wave with principal axes of the ellipse in the directions of ϵ_1 and ϵ_2 . The ratio of semimajor to semiminor axis is $|(1+r)/(1-r)|$, where $E_-/E_+ = r$. If the amplitudes have a phase difference between them, $E_-/E_+ = re^{i\alpha}$, then it is easy to show that the ellipse traced out by the \mathbf{E} vector has its axes rotated by an angle $(\alpha/2)$. Figure 7.4 shows the general case of elliptical polarization and the ellipses traced out by both \mathbf{E} and \mathbf{B} at a given point in space.

For $r = \pm 1$ we get back a linearly polarized wave.

The polarization content of a plane electromagnetic wave is known if it can be written in the form of either (7.19) or (7.24) with known coefficients (E_1, E_2) or (E_+, E_-). In practice, the converse problem arises. Given that the wave is of the form (7.9), how can we determine from observations on the beam the state of polarization in all its particulars? A useful vehicle for this are the four *Stokes parameters*, proposed by G. G. Stokes in 1852. These parameters are quadratic in the field strength and can be determined through intensity measurements only, in conjunction with a linear polarizer and a quarter-wave plate or

Fig. 7.4 Electric field and magnetic induction for an elliptically polarized wave.

equivalents. Their measurement determines completely the state of polarization of the wave.

The Stokes parameters can be motivated by observing that for a wave propagating in the z direction, the scalar products,

$$\epsilon_1 \cdot \mathbf{E}, \quad \epsilon_2 \cdot \mathbf{E}, \quad \epsilon_+^* \cdot \mathbf{E}, \quad \epsilon_-^* \cdot \mathbf{E} \quad (7.25)$$

are the amplitudes of radiation, respectively, with linear polarization in the x direction, linear polarization in the y direction, positive helicity and negative helicity. Note that for circular polarization the *complex conjugate* of the appropriate polarization vector must be used, in accord with (7.23). The squares of these amplitudes give a measure of the intensity of each type of polarization. Phase information is also needed; this is obtained from cross products. We give definitions of the Stokes parameters with respect to both the linear polarization and the circular polarization bases, in terms of the projected amplitudes (7.25) and also explicitly in terms of the magnitudes and relative phases of the components. For the latter purpose we define each of the scalar coefficients in (7.19) and (7.24) as a magnitude times a phase factor:

$$\begin{aligned} E_1 &= a_1 e^{i\delta_1}, & E_2 &= a_2 e^{i\delta_2} \\ E_+ &= a_+ e^{i\delta_+}, & E_- &= a_- e^{i\delta_-} \end{aligned} \quad (7.26)$$

In terms of the linear polarization basis (ϵ_1, ϵ_2), the Stokes parameters are*

$$\begin{aligned} s_0 &= |\epsilon_1 \cdot \mathbf{E}|^2 + |\epsilon_2 \cdot \mathbf{E}|^2 = a_1^2 + a_2^2 \\ s_1 &= |\epsilon_1 \cdot \mathbf{E}|^2 - |\epsilon_2 \cdot \mathbf{E}|^2 = a_1^2 - a_2^2 \\ s_2 &= 2 \operatorname{Re} [(\epsilon_1 \cdot \mathbf{E})^* (\epsilon_2 \cdot \mathbf{E})] = 2a_1 a_2 \cos(\delta_2 - \delta_1) \\ s_3 &= 2 \operatorname{Im} [(\epsilon_1 \cdot \mathbf{E})^* (\epsilon_2 \cdot \mathbf{E})] = 2a_1 a_2 \sin(\delta_2 - \delta_1) \end{aligned} \quad (7.27)$$

* The notation for the Stokes parameters is unfortunately not uniform. Stokes himself used (A, B, C, D); other labelings are (I, Q, U, V) and (I, M, C, S). Our notation is that of *Born and Wolf*.

If the circular polarization basis (ϵ_+ , ϵ_-) is used instead, the definitions read

$$\begin{aligned} s_0 &= |\epsilon_+^* \cdot \mathbf{E}|^2 + |\epsilon_-^* \cdot \mathbf{E}|^2 = a_+^2 + a_-^2 \\ s_1 &= 2 \operatorname{Re} [(\epsilon_+^* \cdot \mathbf{E})^*(\epsilon_-^* \cdot \mathbf{E})] = 2a_+a_- \cos(\delta_- - \delta_+) \\ s_2 &= 2 \operatorname{Im} [(\epsilon_+^* \cdot \mathbf{E})^*(\epsilon_-^* \cdot \mathbf{E})] = 2a_+a_- \sin(\delta_- - \delta_+) \\ s_3 &= |\epsilon_+^* \cdot \mathbf{E}|^2 - |\epsilon_-^* \cdot \mathbf{E}|^2 = a_+^2 - a_-^2 \end{aligned} \quad (7.28)$$

The expressions (7.27) and (7.28) show an interesting rearrangement of roles of the Stokes parameters with respect to the two bases. The parameter s_0 measures the relative intensity of the wave in either case. The parameter s_1 gives the preponderance of x-linear polarization over y-linear polarization, while s_2 and s_3 in the linear basis give phase information. We see from (7.28) that s_3 has the interpretation of the difference in relative intensity of positive and negative helicity, while in this basis s_1 and s_2 concern the phases. The four Stokes parameters are not independent since they depend on only three quantities, a_1 , a_2 , and $\delta_2 - \delta_1$. They satisfy the relation

$$s_0^2 = s_1^2 + s_2^2 + s_3^2 \quad (7.29)$$

Discussion of the operational steps needed to measure the Stokes parameters and so determine the state of polarization of a plane wave would take us too far afield. We refer the reader to Section 13.13 of *Stone* for details. Also neglected, except for the barest mention, is the important problem of quasi-monochromatic radiation. Beams of radiation, even if monochromatic enough for the purposes at hand, actually consist of a superposition of finite wave trains. By Fourier's theorem they thus contain a range of frequencies and are not completely monochromatic. One way of viewing this is to say that the magnitudes and phases (a_i , δ_i) in (7.26) vary slowly in time, slowly, that is, when compared to the frequency ω . The observable Stokes parameters then become averages over a relatively long time interval, and are written as

$$s_0 = 2\langle a_1 a_2 \cos(\delta_2 - \delta_1) \rangle$$

for example, where the brackets indicate the macroscopic time average. One consequence of the averaging process is that the Stokes parameters for a quasi-monochromatic beam satisfy an inequality,

$$s_0^2 \geq s_1^2 + s_2^2 + s_3^2$$

rather than the equality, (7.29). "Natural light," even if monochromatic to a high degree, has $s_1 = s_2 = s_3 = 0$. Further discussion of quasi-monochromatic light and partial coherence can be found in *Born and Wolf*, Chapter 10.

An astrophysical example of the use of Stokes parameters to describe the state of polarization is afforded by the study of optical and radio-frequency radiation from the pulsar in the Crab nebula. The optical light shows some small amount

of linear polarization,* while the radio emission at $\omega \approx 2.5 \times 10^9 \text{ sec}^{-1}$ has a high degree of linear polarization.† At neither frequency is there evidence for circular polarization. Information of this type obviously helps to elucidate the mechanism of radiation from these fascinating objects.

7.3 Reflection and Refraction of Electromagnetic Waves at a Plane Interface between Dielectrics

The reflection and refraction of light at a plane surface between two media of different dielectric properties are familiar phenomena. The various aspects of the phenomena divide themselves into two classes.

(1) Kinematic properties:

(a) Angle of reflection equals angle of incidence.

(b) Snell's law: $\frac{\sin i}{\sin r} = \frac{n'}{n}$, where i, r are the angles of incidence and refraction, while n, n' are the corresponding indices of refraction.

(2) Dynamic properties:

(a) Intensities of reflected and refracted radiation.

(b) Phase changes and polarization.

The kinematic properties follow immediately from the wave nature of the phenomena and the fact that there are boundary conditions to be satisfied. But they do not depend on the detailed nature of the waves or the boundary conditions. On the other hand, the dynamic properties depend entirely on the specific nature of electromagnetic fields and their boundary conditions.

The coordinate system and symbols appropriate to the problem are shown in Fig. 7.5. The media below and above the plane $z=0$ have permeabilities and dielectric constants μ, ϵ and μ', ϵ' , respectively. The indices of refraction, defined through (7.5) as ck/ω , are $n = \sqrt{\mu\epsilon}$ and $n' = \sqrt{\mu'\epsilon'}$. A plane wave with wave vector \mathbf{k} and frequency ω is incident from medium μ, ϵ . The refracted and reflected waves have wave vectors \mathbf{k}' and \mathbf{k}'' , respectively, and \mathbf{n} is a unit normal directed from medium μ, ϵ into medium μ', ϵ' .

According to (7.18), the three waves are

INCIDENT

$$\left. \begin{aligned} \mathbf{E} &= \mathbf{E}_0 e^{i\mathbf{k} \cdot \mathbf{x} - i\omega t} \\ \mathbf{B} &= \sqrt{\mu\epsilon} \frac{\mathbf{k} \times \mathbf{E}}{k} \end{aligned} \right\} \quad (7.30)$$

* E. J. Wampler, J. D. Scargle, and J. S. Miller, *Astrophys. J. Lett.* **157** L1 (1969).

† D. A. Graham, A. G. Lyne, and F. G. Smith, *Nature* **225**, 526 (7 February 1970), D. B. Campbell, C. Heiles, and J. M. Rankin, *Nature* **225**, 527 (7 February 1970).

Fig. 7.5 Incident wave \mathbf{k} strikes plane interface between different media, giving rise to a reflected wave \mathbf{k}'' and a refracted wave \mathbf{k}' .

REFRACTED

$$\left. \begin{aligned} \mathbf{E}' &= \mathbf{E}_0' e^{i\mathbf{k}' \cdot \mathbf{x} - i\omega t} \\ \mathbf{B}' &= \sqrt{\mu' \epsilon'} \frac{\mathbf{k}' \times \mathbf{E}'}{k'} \end{aligned} \right\} \quad (7.31)$$

REFLECTED

$$\left. \begin{aligned} \mathbf{E}'' &= \mathbf{E}_0'' e^{i\mathbf{k}'' \cdot \mathbf{x} - i\omega t} \\ \mathbf{B}'' &= \sqrt{\mu \epsilon} \frac{\mathbf{k}'' \times \mathbf{E}''}{k} \end{aligned} \right\} \quad (7.32)$$

The wave numbers have the magnitudes

$$\left. \begin{aligned} |\mathbf{k}| &= |\mathbf{k}''| = k = \frac{\omega}{c} \sqrt{\mu \epsilon} \\ |\mathbf{k}'| &= k' = \frac{\omega}{c} \sqrt{\mu' \epsilon'} \end{aligned} \right\} \quad (7.33)$$

The existence of boundary conditions at $z=0$, which boundary conditions must be satisfied at all points on the plane at all times, implies that the spatial (and time) variation of all fields must be the same at $z=0$. Consequently, we must have the phase factors all equal at $z=0$,

$$(\mathbf{k} \cdot \mathbf{x})_{z=0} = (\mathbf{k}' \cdot \mathbf{x})_{z=0} = (\mathbf{k}'' \cdot \mathbf{x})_{z=0} \quad (7.34)$$

independent of the nature of the boundary conditions. Equation (7.34) contains the kinematic aspects of reflection and refraction. We see immediately that all three wave vectors must lie in a plane. Furthermore, in the notation of Fig. 7.5,

$$k \sin i = k' \sin r = k'' \sin r' \quad (7.35)$$

Since $k'' = k$, we find $i = r'$; the angle of incidence equals the angle of reflection. Snell's law is

$$\frac{\sin i}{\sin r} = \frac{k'}{k} = \sqrt{\frac{\mu' \epsilon'}{\mu \epsilon}} = \frac{n'}{n} \quad (7.36)$$

The dynamic properties are contained in the boundary conditions—normal components of \mathbf{D} and \mathbf{B} are continuous; tangential components of \mathbf{E} and \mathbf{H} are continuous. In terms of fields (7.30)–(7.32) these boundary conditions at $z=0$ are:

$$\left. \begin{aligned} & [\epsilon(\mathbf{E}_0 + \mathbf{E}_0'') - \epsilon' \mathbf{E}_0'] \cdot \mathbf{n} = 0 \\ & [\mathbf{k} \times \mathbf{E}_0 + \mathbf{k}'' \times \mathbf{E}_0'' - \mathbf{k}' \times \mathbf{E}_0'] \cdot \mathbf{n} = 0 \\ & (\mathbf{E}_0 + \mathbf{E}_0'' - \mathbf{E}_0') \times \mathbf{n} = 0 \\ & \left[\frac{1}{\mu} (\mathbf{k} \times \mathbf{E}_0 + \mathbf{k}'' \times \mathbf{E}_0'') - \frac{1}{\mu'} (\mathbf{k}' \times \mathbf{E}_0') \right] \times \mathbf{n} = 0 \end{aligned} \right\} \quad (7.37)$$

In applying these boundary conditions it is convenient to consider two separate situations, one in which the incident plane wave is linearly polarized with its polarization vector perpendicular to the plane of incidence (the plane defined by \mathbf{k} and \mathbf{n}), and the other in which the polarization vector is parallel to the plane of incidence. The general case of arbitrary elliptic polarization can be obtained by appropriate linear combinations of the two results, following the methods of Section 7.2.

We first consider the electric field perpendicular to the plane of incidence, as shown in Fig. 7.6. All the electric fields are shown directed away from the viewer. The orientations of the \mathbf{B} vectors are chosen to give a positive flow of energy in the direction of the wave vectors. Since the electric fields are all parallel to the surface, the first boundary condition in (7.37) yields nothing. The

Fig. 7.6 Reflection and refraction with polarization perpendicular to the plane of incidence.

Fig. 7.7 Reflection and refraction with polarization parallel to the plane of incidence.

third and fourth equations in (7.37) give

$$\left. \begin{aligned} E_0 + E_0'' - E_0' &= 0 \\ \sqrt{\frac{\epsilon}{\mu}} (E_0 - E_0'') \cos i - \sqrt{\frac{\epsilon'}{\mu'}} E_0' \cos r &= 0 \end{aligned} \right\} \quad (7.38)$$

while the second, using Snell's law, duplicates the third. The relative amplitudes of the refracted and reflected waves can be found from (7.38). These are:

E PERPENDICULAR TO PLANE OF INCIDENCE

$$\left. \begin{aligned} \frac{E_0'}{E_0} &= \frac{2n \cos i}{n \cos i + \frac{\mu}{\mu'} \sqrt{n'^2 - n^2 \sin^2 i}} \\ \frac{E_0''}{E_0} &= \frac{n \cos i - \frac{\mu}{\mu'} \sqrt{n'^2 - n^2 \sin^2 i}}{n \cos i + \frac{\mu}{\mu'} \sqrt{n'^2 - n^2 \sin^2 i}} \end{aligned} \right\} \quad (7.39)$$

The square root in these expressions is $n' \cos r$, but Snell's law has been used to express it in terms of the angle of incidence. For optical frequencies it is usually permitted to put $\mu/\mu' = 1$. Equations (7.39) and (7.41) and (7.42) below, are most often employed in optical contexts with real n and n' , but they are also valid for complex dielectric constants.

If the electric field is parallel to the plane of incidence, as shown in Fig. 7.7, the boundary conditions involved are normal D , tangential E , and tangential H [the first, third, and fourth equations in (7.37)]. The tangential E and H continuous demand that

$$\left. \begin{aligned} \cos i (E_0 - E_0'') - \cos r E_0' &= 0 \\ \sqrt{\frac{\epsilon}{\mu}} (E_0 + E_0'') - \sqrt{\frac{\epsilon'}{\mu'}} E_0' &= 0 \end{aligned} \right\} \quad (7.40)$$

Normal D continuous, plus Snell's law, merely duplicates the second of these equations. The relative amplitudes of refracted and reflected fields are therefore

E PARALLEL TO PLANE OF INCIDENCE

$$\left. \begin{aligned} \frac{E'_0}{E_0} &= \frac{2nn' \cos i}{\frac{\mu}{\mu'} n'^2 \cos i + n\sqrt{n'^2 - n^2 \sin^2 i}} \\ \frac{E''_0}{E_0} &= \frac{\frac{\mu}{\mu'} n'^2 \cos i - n\sqrt{n'^2 - n^2 \sin^2 i}}{\frac{\mu}{\mu'} n'^2 \cos i + n\sqrt{n'^2 - n^2 \sin^2 i}} \end{aligned} \right\} \quad (7.41)$$

For normal incidence ($i=0$), both (7.39) and (7.41) reduce to

$$\left. \begin{aligned} \frac{E'_0}{E_0} &= \frac{2}{\sqrt{\frac{\mu\epsilon'}{\mu'\epsilon}} + 1} \rightarrow \frac{2n}{n' + n} \\ \frac{E''_0}{E_0} &= \frac{\sqrt{\frac{\mu\epsilon'}{\mu'\epsilon}} - 1}{\sqrt{\frac{\mu\epsilon'}{\mu'\epsilon}} + 1} \rightarrow \frac{n' - n}{n' + n} \end{aligned} \right\} \quad (7.42)$$

where the results on the right hold for $\mu' = \mu$. For the reflected wave the sign convention is that for polarization parallel to the plane of incidence. This means that if $n' > n$ there is a phase reversal for the reflected wave.

7.4 Polarization by Reflection and Total Internal Reflection

Two aspects of the dynamical relations on reflection and refraction are worthy of mention. The first is that for polarization parallel to the plane of incidence there is an angle of incidence, called *Brewster's angle*, for which there is no reflected wave. With $\mu' = \mu$ for simplicity, we find that the amplitude of the reflected wave in (7.41) vanishes when the angle of incidence is equal to Brewster's angle,

$$i_B = \tan^{-1} \left(\frac{n'}{n} \right) \quad (7.43)$$

For a typical ratio $(n'/n) = 1.5$, $i_B \approx 56^\circ$. If a plane wave of mixed polarization is incident on a plane interface at the Brewster angle, the reflected radiation is *completely plane polarized* with polarization vector *perpendicular* to the plane of incidence. This behavior can be utilized to produce beams of plane-polarized light, but is not as efficient as other means employing anisotropic properties of some dielectric media. Even if the unpolarized wave is reflected at angles other

than the Brewster angle, there is a tendency for the reflected wave to be predominantly polarized perpendicular to the plane of incidence. The success of dark glasses which selectively transmit only one direction of polarization depends on this fact. In the domain of radiofrequencies, receiving antennas can be so oriented as to discriminate against surface-reflected waves (and also waves reflected from the ionosphere) in favor of the directly transmitted wave.

The second phenomenon is called *total internal reflection*. The word internal implies that the incident and reflected waves are in a medium of larger index of refraction than the refracted wave ($n > n'$). Snell's law (7.36) shows that, if $n > n'$, then $r > i$. Consequently, $r = \pi/2$ when $i = i_0$, where

$$i_0 = \sin^{-1} \left(\frac{n'}{n} \right) \quad (7.44)$$

For waves incident at $i = i_0$, the refracted wave is propagated parallel to the surface. There can be no energy flow across the surface. Hence at that angle of incidence there must be total reflection. What happens if $i > i_0$? To answer this we first note that, for $i > i_0$, $\sin r > 1$. This means that r is a complex angle with a purely imaginary cosine.

$$\cos r = i \sqrt{\left(\frac{\sin i}{\sin i_0} \right)^2 - 1} \quad (7.45)$$

The meaning of these complex quantities becomes clear when we consider the propagation factor for the refracted wave:

$$e^{i\mathbf{k}' \cdot \mathbf{x}} = e^{ik'(x \sin r + z \cos r)} = e^{-k'[(\sin i / \sin i_0)^2 - 1]^{1/2} z} e^{ik'(\sin i / \sin i_0)x} \quad (7.46)$$

This shows that, for $i > i_0$, the refracted wave is propagated only parallel to the surface and is attenuated exponentially beyond the interface. The attenuation occurs within a very few wavelengths of the boundary, except for $i \approx i_0$.

Even though fields exist on the other side of the surface there is no energy flow through the surface. Hence total internal reflection occurs for $i \geq i_0$. The lack of energy flow can be verified by calculating the time-averaged *normal* component of the Poynting vector just inside the surface:

$$\mathbf{S} \cdot \mathbf{n} = \frac{c}{8\pi} \operatorname{Re} [\mathbf{n} \cdot (\mathbf{E}' \times \mathbf{H}'^*)] \quad (7.47)$$

With $\mathbf{H}' = \frac{c}{\mu'\omega} (\mathbf{k}' \times \mathbf{E}')$, we find

$$\mathbf{S} \cdot \mathbf{n} = \frac{c^2}{8\pi\omega\mu'} \operatorname{Re} [(\mathbf{n} \cdot \mathbf{k}') |\mathbf{E}_0|^2] \quad (7.48)$$

But $\mathbf{n} \cdot \mathbf{k}' = k' \cos r$ is purely imaginary, so that $\mathbf{S} \cdot \mathbf{n} = 0$.

The purely imaginary value (7.45) of $\cos r$, times n' , is the appropriate quantity to replace the square root appearing in the Fresnel formula, (7.39) and

(7.41). Inspection shows that the ratios E''/E_0 are now of modulus unity, as is expected physically for *total* internal reflection. The reflected wave does, however, suffer a phase change that is different for the two kinds of incidence and depends on the angle of incidence and on (n/n') . These phase changes can be utilized to convert one kind of polarization into another. Fresnel's rhombus is one such device, whereby linearly polarized light with equal amplitudes in the plane of incidence and perpendicular to it is converted by two successive internal reflections, each involving a relative phase change of 45° , into circularly polarized light (see *Born and Wolf*, p. 50).

The phenomenon of total internal reflection is exploited in many applications where it is required to transmit light without loss in intensity. In nuclear and particle physics plastic "light pipes" are used to carry light emitted from a scintillation crystal because of the passage of an ionizing particle to a photomultiplier tube, where it is converted into a useful electric signal. The photomultiplier must often be some distance away from the scintillation crystal because of space limitations or magnetic fields which disturb its performance. If the light pipe is large in cross section compared to a wavelength of the radiation involved, the considerations presented here for a plane interface have approximate validity. When the dielectric medium has cross-sectional dimensions of the order of a wavelength, however, the precise geometry must be taken into account. Then the propagation is that of a dielectric wave guide (see Section 8.10).

7.5 Frequency Dispersion Characteristics of Dielectrics, Conductors, and Plasmas

In Section 7.1 the permeability and susceptibility were assumed independent of frequency. This absence of dispersion had as its consequence the propagation of wave trains undistorted, as implied by the general solution (7.8). In reality all media show some dispersion. Only over a limited range of frequencies, or in vacuum, can the velocity of propagation be treated as constant in frequency. Of course, all the results of the previous sections that involve a single frequency component are valid in the presence of dispersion. The values of μ and ϵ need only be interpreted as those appropriate to the frequency being considered. Where a superposition of a range of frequencies occurs, however, new effects arise as a result of the frequency dependence of ϵ and μ . In order to examine some of these consequences we need to develop at least a simple model of dispersion.

(a) Simple Model for $\epsilon(\omega)$

Almost all of the physics of dispersion is illustrated by an extension to time-varying fields of the classical model described in Section 4.6. For simplicity we will neglect the difference between the applied electric field and the local

field. The model is therefore appropriate only for substances of relatively low density. [This deficiency can be removed by use of (4.69), if desired.] The permeability will be taken equal to unity. The equation of motion for an electron of charge $-e$ bound by a harmonic force (4.71) and acted on by an electric field $\mathbf{E}(\mathbf{x}, t)$ is

$$m[\ddot{\mathbf{x}} + \gamma\dot{\mathbf{x}} + \omega_0^2\mathbf{x}] = -e\mathbf{E}(\mathbf{x}, t) \quad (7.49)$$

where γ measures the phenomenological damping force. Magnetic force effects are neglected in (7.49). We make the additional approximation that the amplitude of oscillation is small enough that the electric field can be evaluated at the average position of the electron. If the field varies harmonically in time with frequency ω as $e^{-i\omega t}$, the dipole moment contributed by one electron is

$$\mathbf{p} = -e\mathbf{x} = \frac{e^2}{m} (\omega_0^2 - \omega^2 - i\omega\gamma)^{-1} \mathbf{E} \quad (7.50)$$

If we suppose that there are N molecules per unit volume with Z electrons per molecule, and that, instead of a single binding frequency for all, there are f_i electrons per molecule with binding frequency ω_i and damping constant γ_i , then the dielectric constant, $\epsilon = 1 + 4\pi\chi_e$, is given by

$$\epsilon(\omega) = 1 + \frac{4\pi N e^2}{m} \sum_i f_i (\omega_i^2 - \omega^2 - i\omega\gamma_i)^{-1} \quad (7.51)$$

where the oscillator strengths f_i satisfy the sum rule,

$$\sum_i f_i = Z \quad (7.52)$$

With suitable quantum-mechanical definitions of f_i , γ_i , and ω_i , (7.51) is an accurate description of the atomic contribution to the dielectric constant.

(b) Anomalous Dispersion and Resonant Absorption

The damping constants γ_i are generally small compared with the binding or resonant frequencies ω_i . This means that $\epsilon(\omega)$ is approximately real for most frequencies. The factor $(\omega_i^2 - \omega^2)^{-1}$ is positive for $\omega < \omega_i$ and negative for $\omega > \omega_i$. Thus, at low frequencies, below the smallest ω_i , all the terms in the sum in (7.51) contribute with the same positive sign and $\epsilon(\omega)$ is greater than unity. As successive ω_i values are passed, more and more negative terms occur in the sum, until finally the whole sum is negative and $\epsilon(\omega)$ is less than one. In the neighborhood of any ω_i , of course, there is rather violent behavior. The real part of the denominator in (7.51) vanishes for that term at $\omega = \omega_i$ and the term is large and purely imaginary. The general features of the real and imaginary parts of $\epsilon(\omega)$ around two successive resonant frequencies are shown in Fig. 7.8. *Normal dispersion* is associated with an increase in $\text{Re } \epsilon(\omega)$ with ω , *anomalous*

Fig. 7.8 Real and imaginary parts of the dielectric constant $\epsilon(\omega)$ in the neighborhood of two resonances. The region of anomalous dispersion is also the frequency interval where absorption occurs.

dispersion with the reverse. Normal dispersion is seen to occur everywhere except in the neighborhood of a resonant frequency. And only where there is anomalous dispersion is the imaginary part of ϵ appreciable. Since a positive imaginary part to ϵ represents dissipation of energy from the electromagnetic wave into the medium, the regions where $\text{Im } \epsilon$ is large are called regions of *resonant absorption*.*

The attenuation of a plane wave is most directly expressed in terms of the real and imaginary parts of the wave number k . If the wave number is written as

$$k = \beta + i \frac{\alpha}{2} \quad (7.53)$$

then the parameter α is known as the attenuation constant or absorption coefficient. The *intensity* of the wave falls off as $e^{-\alpha z}$. Equation (7.5) yields the

* If $\text{Im } \epsilon < 0$, energy is given to the wave by the medium; amplification occurs, as in a maser or laser. See M. Borenstein and W. E. Lamb, *Phys. Rev.* **A5**, 1298 (1972).

connection between (α, β) and $(\text{Re } \epsilon, \text{Im } \epsilon)$:

$$\begin{aligned}\beta^2 - \frac{\alpha^2}{4} &= \frac{\omega^2}{c^2} \text{Re } \epsilon \\ \beta\alpha &= \frac{\omega^2}{c^2} \text{Im } \epsilon\end{aligned}\tag{7.54}$$

If $\alpha \ll \beta$, as occurs unless the absorption is very strong or $\text{Re } \epsilon$ is negative, the attenuation constant α can be written approximately as

$$\alpha \approx \frac{\text{Im } \epsilon(\omega)}{\text{Re } \epsilon(\omega)} \beta\tag{7.55}$$

where $\beta = \sqrt{\text{Re } \epsilon} \omega/c$. The fractional decrease in intensity per wavelength divided by 2π is thus given by the ratio, $\text{Im } \epsilon/\text{Re } \epsilon$.

(c) *Low Frequency Behavior, Electric Conductivity*

In the limit $\omega \rightarrow 0$ there is a qualitative difference in the response of the medium depending on whether the lowest resonant frequency is zero or nonzero. For insulators the lowest resonant frequency is different from zero. Then at $\omega = 0$ the molecular polarizability is given by (4.73), corresponding to the limit $\omega = 0$ in (7.51). The elementary aspects of dielectrics in the static limit have been discussed in Section 4.6.

If some fraction f_0 of the electrons per molecule are “free” in the sense of having $\omega_0 = 0$, the dielectric constant is singular at $\omega = 0$. If the contribution of the free electrons is exhibited separately, (7.51) becomes

$$\epsilon(\omega) = \epsilon_0 + i \frac{4\pi N e^2 f_0}{m(\gamma_0 - i\omega)}\tag{7.56}$$

where ϵ_0 is the contribution of all the other dipoles. The singular behavior can be understood if we examine the Maxwell-Ampère equation,

$$\nabla \times \mathbf{H} = \frac{4\pi}{c} \mathbf{J} + \frac{1}{c} \frac{d\mathbf{D}}{dt}$$

and assume that the medium obeys Ohm’s law, $\mathbf{J} = \sigma \mathbf{E}$ and has a “normal” dielectric constant ϵ_0 . With harmonic time dependence the equation becomes

$$\nabla \times \mathbf{H} = -i \frac{\omega}{c} \left(\epsilon_0 + i \frac{4\pi\sigma}{\omega} \right) \mathbf{E}\tag{7.57}$$

If, on the other hand, we did not insert Ohm’s law explicitly but attributed instead all the properties of the medium to the dielectric constant, we would identify the quantity in brackets on the right-hand side of (7.57) with $\epsilon(\omega)$. Comparison with (7.56) yields an expression for the conductivity:

$$\sigma = \frac{f_0 N e^2}{m(\gamma_0 - i\omega)}\tag{7.58}$$

This is essentially the model of Drude (1900) for the electrical conductivity, with $f_0 N$ being the number of free electrons per unit volume in the medium. The damping constant γ_0/f_0 can be determined empirically from experimental data on the conductivity. For copper, $N \approx 8 \times 10^{22}$ atoms/cm³ and at normal temperatures the low frequency conductivity is $\sigma \approx 5 \times 10^{17}$ sec⁻¹. This gives $\gamma_0/f_0 \approx 3 \times 10^{13}$ sec⁻¹. Assuming that $f_0 \sim 1$, this shows that up to frequencies well beyond the microwave region ($\omega \lesssim 10^{11}$ sec⁻¹) conductivities of metals are essentially real (i.e., current in phase with the field) and independent of frequency. At higher frequencies (in the infrared and beyond) the conductivity is complex and varies with frequency in a way described qualitatively by the simple result (7.58). The problem of electrical conductivity is really a quantum-mechanical one in which the Pauli principle plays an important role. The free electrons are actually valence electrons of the isolated atoms that become quasi-free and move relatively unimpeded through the lattice (provided their energies lie in certain intervals or bands) when the atoms are brought together to form a solid. The damping effects come from collisions involving appreciable momentum transfer between the electrons and lattice vibrations, lattice imperfections, and impurities.*

The above considerations show that the distinction between dielectrics and conductors is an artificial one, at least away from $\omega = 0$. If the medium possess free electrons it is a conductor at low frequencies; otherwise, an insulator.† But at nonzero frequencies the “conductivity” contribution to $\epsilon(\omega)$ (7.51) merely appears as a resonant amplitude like the rest. The dispersive properties of the medium can be attributed as well to a complex dielectric constant as to a frequency-dependent conductivity and a dielectric constant.

(d) High-Frequency Limit, Plasma Frequency

At frequencies far above the highest resonant frequency the dielectric constant (7.51) takes on the simple form

$$\epsilon(\omega) \approx 1 - \frac{\omega_p^2}{\omega^2} \quad (7.59)$$

where

$$\omega_p^2 = \frac{4\pi NZe^2}{m} \quad (7.60)$$

The frequency ω_p , which depends only on the total number NZ of electrons per

* See A. H. Wilson, *Theory of Metals*, 2nd edition, Cambridge University Press (1953), or W. R. Beam, *Electronics of Solids*, McGraw-Hill, New York (1965).

† In terms of the quantum-mechanical band structure of the solid, the conductor has some electrons in a partially filled band, while the insulator has its bands filled to the full extent permitted by the Pauli principle. A “free” electron must have nearby energy-conserving quantum states to which it can move. In a partially filled band there are such states, but a filled band has, by definition, no such states available.

unit volume, is called the *plasma frequency* of the medium. The wave number is given in the limit by

$$ck = \sqrt{\omega^2 - \omega_p^2} \quad (7.61)$$

Sometimes (7.61) is expressed as $\omega^2 = \omega_p^2 + c^2 k^2$, and is called a dispersion relation or equation for $\omega = \omega(k)$. In dielectric media, (7.59) only applies for $\omega^2 \gg \omega_p^2$. The dielectric constant is then close to unity, although slightly less, and increases with frequency somewhat as the highest frequency part of the curve shown in Fig. 7.8. The wave number is real and varies with frequency as for a mode in a wave guide with cut-off frequency ω_p . (See Fig. 8.4.)

In certain situations, such as in the ionosphere or in a tenuous electronic plasma in the laboratory, the electrons are free and the damping is negligible. Then (7.59) holds over a wide range of frequencies, including $\omega < \omega_p$. For frequencies lower than the plasma frequency the wave number (7.61) is purely imaginary. Such waves incident on a plasma are reflected and the fields inside fall off exponentially with distance from the surface. At $\omega = 0$ the attenuation constant is

$$\alpha_{\text{plasma}} \simeq \frac{2\omega_p}{c} \quad (7.62)$$

On the laboratory scale, plasma densities are of the order of 10^{12} – 10^{16} electrons/cm³. This means $\omega_p \approx 6 \times 10^{10}$ – 6×10^{12} sec⁻¹, so that typically attenuation lengths (α^{-1}) are of the order of 0.2 cm– 2×10^{-3} cm for static or low frequency fields. The expulsion of fields from within a plasma is a well-known effect in controlled thermonuclear processes and is exploited in attempts at confinement of hot plasma (see Section 10.5).

The reflectivity of metals at optical and higher frequencies is caused by essentially the same behavior as for the tenuous plasma. The dielectric constant of a metal is given by (7.56). At high frequencies ($\omega \gg \gamma_0$) this takes the approximate form,

$$\epsilon(\omega) \simeq \epsilon_0(\omega) - \frac{\omega_p^2}{\omega^2}$$

where $\omega_p^2 = 4\pi ne^2/m^*$ is the plasma frequency of the conduction electrons, given an effective mass m^* to include partially the effects of binding. For $\omega \ll \omega_p$ the behavior of light incident on the metal is approximately the same as for the plasma described by (7.59). The light penetrates only a very short distance into the metal and is almost entirely reflected. But when the frequency is increased into the domain where $\epsilon(\omega) > 0$, the metal suddenly can transmit light and its reflectivity changes drastically. This occurs typically in the ultraviolet and leads to the terminology, ultraviolet transparency of metals. Determination of the

critical frequency gives information on the density or the effective mass of the conduction electrons.*

(e) *Index of Refraction and Absorption Coefficient of Liquid Water as a Function of Frequency*

As an example of the overall frequency behavior of the real part of the index of refraction and the absorption coefficient of a real medium, we take the ubiquitous substance, water. Our intent is to give a broad view and to indicate the tremendous variations that are possible, rather than to discuss specific details. Accordingly, we show in Fig. 7.9, on a log-log plot with 20 decades in frequency and 11 decades in absorption, a compilation of the gross features of $n(\omega) = \text{Re} \sqrt{\mu\epsilon}$ and $\alpha(\omega) = 2 \text{Im} \sqrt{\mu\epsilon} \omega/c$ for liquid water at N.T.P. The upper part of the graph shows the interesting, but not spectacular, behavior of $n(\omega)$. At very low frequencies, $n(\omega) \approx 9$, a value arising from the partial orientation of the permanent dipole moments of the water molecules. Above 10^{10} Hz the curve falls relatively smoothly to the structure in the infrared. In the visible region, shown by the vertical dashed lines, $n(\omega) \approx 1.34$, with little variation. Then in the ultraviolet there is more structure. Above 6×10^{15} Hz ($h\nu \approx 25$ eV) there are no data on the real part of the index of refraction. The asymptotic approach to unity shown in the figure assumes (7.59).

Much more dramatic is the behavior of the absorption coefficient α . At frequencies below 10^8 Hz the absorption coefficient is extremely small. The data seem unreliable (two different sets are shown), probably because of variations in sample purity. As the frequency increases toward 10^{11} Hz, the absorption coefficient increases rapidly to $\alpha \approx 10^2 \text{ cm}^{-1}$, corresponding to an attenuation length of 100 microns in liquid water. This is the well-known microwave absorption by water. It is the phenomenon (in moist air) that terminated the trend during World War II toward better and better resolution in radar by going to shorter and shorter wavelengths.

In the infrared region absorption bands associated with vibrational modes of the molecule and possibly oscillations of a molecule in the field of its neighbors cause the absorption to reach peak values of $\alpha \approx 10^4 \text{ cm}^{-1}$. Then the absorption coefficient falls precipitously over $7\frac{1}{2}$ decades to a value of $\alpha < 3 \times 10^{-3} \text{ cm}^{-1}$ in a narrow frequency range between 4×10^{14} Hz and 8×10^{14} Hz. It then rises again by more than 8 decades by 2×10^{15} Hz. This is a dramatic absorption *window* in what we call the *visible region*. The extreme transparency of water here has its origins in the basic energy level structure of the atoms and molecules. The reader may meditate on the fundamental question of biological evolution on this water-soaked planet, of why animal eyes see the spectrum from red to violet and of why the grass is green. Mother Nature has certainly exploited her window! In

Fig. 7.9 The index of refraction (top) and absorption coefficient (bottom) for liquid water as a function of linear frequency. Also shown as abscissas are an energy scale (arrows) and a wavelength scale (vertical lines). The visible region of the frequency spectrum is indicated by the vertical dashed lines. The absorption coefficient for sea water is indicated by the dashed diagonal line at the left. Note that the scales are logarithmic in both directions.

the very far ultraviolet the absorption has a peak value of $\alpha \approx 1.1 \times 10^6 \text{ cm}^{-1}$ at $\nu \approx 5 \times 10^{15} \text{ Hz}$ (21 eV). This is exactly at the plasmon energy $\hbar\omega_p$, corresponding to a collective excitation of all the electrons in the molecule. The attenuation is given in order of magnitude by (7.62). At higher frequencies data are absent until the photoelectric effect, and then Compton scattering and other high-energy processes take over. There the nuclear physicists have studied the absorption in detail. The behavior is basically governed by the atomic properties and the density, not by the fact that the substance is water.

At the low frequency end of the graph in Fig. 7.9 we have indicated the absorption coefficient of *sea water*. At low frequencies, sea water has an electrical conductivity $\sigma \approx 4 \times 10^{10} \text{ sec}^{-1}$ (4.4 mhos/meter). From (7.57) we find that below about 10^8 Hz $\alpha \approx (8\pi\omega\sigma/c^2)^{1/2}$. The absorption coefficient is thus proportional to $\sqrt{\omega}$ and becomes very small at low frequencies. The line shown is $\alpha (\text{cm}^{-1}) = 8.4 \times 10^{-5} \sqrt{\nu(\text{Hz})}$. At 10^2 Hz , the attenuation length in sea water is $\alpha^{-1} \approx 10$ meters. This means that 1 percent of the intensity at the surface will survive at 50 meters below the surface. If one had a large fleet of submarines scattered throughout the oceans of the world and one wished to be able to send messages to them from a land base while they remained submerged, one would be led to consider extremely low frequency (ELF) communications. The existence of prominent resonances of the earth-ionosphere cavity in the range from 8 Hz to a few hundred Hz (see Section 8.9) makes that region of the frequency spectrum specially attractive, as does the reduced attenuation. With wavelengths of the order of $5 \times 10^3 \text{ km}$, very large antennas are needed (still small compared to a wavelength!). Speculations and more along these lines can be traced from time to time in the daily press.*

7.6 Simplified Model of Propagation in the Ionosphere and Magnetosphere

The propagation of electromagnetic waves in the ionosphere is described in zeroth approximation by the dielectric constant (7.59), but the presence of the earth's magnetic field modifies the behavior significantly. The influence of a static external magnetic field is also present for many laboratory plasmas. To illustrate the influence of an external magnetic field, we consider the simple problem of a tenuous electronic plasma of uniform density with a strong, static, uniform, magnetic induction \mathbf{B}_0 and transverse waves propagating parallel to the direction of \mathbf{B}_0 . (The more general problem of an arbitrary direction of propagation is contained in Problem 10.7.) If the amplitude of electronic motion is small and collisions are neglected, the equation of motion is approximately

$$m\ddot{\mathbf{x}} - \frac{e}{c} \mathbf{B}_0 \times \dot{\mathbf{x}} = -e\mathbf{E}e^{-i\omega t} \quad (7.63)$$

* *New York Times*, October 14, 1969, p. 49, column 1; August 19, 1973, p. 8, column 1.

where the influence of the \mathbf{B} field of the transverse wave has been neglected compared to the static induction \mathbf{B}_0 and the electronic charge has been written as $-e$. It is convenient to consider the transverse waves as circularly polarized. Thus we write

$$\mathbf{E} = (\epsilon_1 \pm i\epsilon_2)E \quad (7.64)$$

and a similar expression for \mathbf{x} . Since the direction of \mathbf{B}_0 is taken orthogonal to ϵ_1 and ϵ_2 , the cross product in (7.63) has components only in the directions ϵ_1 and ϵ_2 and the transverse components decouple. The steady-state solution of (7.63) is

$$\mathbf{x} = \frac{e}{m\omega(\omega \mp \omega_B)} \mathbf{E} \quad (7.65)$$

where ω_B is the frequency of precession of a charged particle in a magnetic field,

$$\omega_B = \frac{eB_0}{mc} \quad (7.66)$$

The frequency dependence of (7.65) can be understood by the transformation of (7.63) to a coordinate system precessing with frequency ω_B about the direction of \mathbf{B}_0 . The static magnetic field is eliminated; the rate of change of momentum there is caused by a rotating electric field of effective frequency $(\omega \pm \omega_B)$, depending on the sign of the circular polarization.

The amplitude of oscillation (7.65) gives a dipole moment for each electron and yields, for a bulk sample, the dielectric constant

$$\epsilon_{\mp} = 1 - \frac{\omega_p^2}{\omega(\omega \mp \omega_B)} \quad (7.67)$$

The upper sign corresponds to a positive helicity wave (left-handed circular polarization in the optics terminology), while the lower is for negative helicity. For propagation antiparallel to the magnetic field \mathbf{B}_0 , the signs are reversed. This is the extension of (7.59) to include a static magnetic induction. It is not completely general, since it applies only to waves propagating along the static field direction. But even in this simple example we see the essential characteristic that waves of right-handed and left-handed circular polarizations propagate differently. The ionosphere is birefringent. For propagation in directions other than parallel to the static field \mathbf{B}_0 it is straightforward to show that, if terms of the order of ω_B^2 are neglected compared to ω^2 and $\omega\omega_B$, the dielectric constant is still given by (7.67). But the precession frequency (7.66) is now to be interpreted as that due to only the component of B_0 parallel to the direction of propagation. This means that ω_B in (7.67) is a function of angle—the medium is not only birefringent, but also anisotropic (see Problem 10.7).

For the ionosphere a typical maximum density of free electrons is 10^4 – 10^6

Fig. 7.10 Dielectric constants as functions of frequency for model of the ionosphere (tenuous electronic plasma in a static, uniform magnetic induction). $\epsilon_{\pm}(\omega)$ apply to right and left circularly polarized waves propagating parallel to the magnetic field. ω_B is the gyration frequency: ω_p is the plasma frequency. The two sets of curves correspond to $\omega_p/\omega_B = 2.0, 0.5$.

electrons/cm³, corresponding to a plasma frequency of the order of $\omega_p \approx 6 \times 10^6 - 6 \times 10^7 \text{ sec}^{-1}$. If we take a value of 0.3 gauss as representative of the earth's magnetic field, the precession frequency is $\omega_B = 6 \times 10^6 \text{ sec}^{-1}$.

Figure 7.10 shows ϵ_{\pm} as a function of frequency for two values of the ratio of (ω_p/ω_B). In both examples there are wide intervals of frequency where one of ϵ_{+} or ϵ_{-} is positive while the other is negative. At such frequencies one state of circular polarization cannot propagate in the plasma. Consequently a wave of that polarization incident on the plasma will be totally reflected. The other state of polarization will be partially transmitted. Thus, when a linearly polarized wave is incident on a plasma, the reflected wave will be elliptically polarized, with its major axis generally rotated away from the direction of the polarization of the incident wave.

The behavior of radio waves reflected from the ionosphere is explicable in terms of these ideas, but the presence of several layers of plasma with densities and relative positions varying with height and time makes the problem considerably more complicated than our simple example. The electron densities at various heights can be inferred by studying the reflection of pulses of radiation transmitted vertically upwards. The number n_0 of free electrons per unit volume increases slowly with height in a given layer of the ionosphere, as shown in Fig.

7.11, reaches a maximum, and then falls abruptly with further increase in height. A pulse of a given frequency ω_1 enters the layer without reflection because of the slow change in n_0 . When the density n_0 is large enough, however, $\omega_p(h_1) \approx \omega_1$. Then the dielectric constants (7.67) vanish and the pulse is reflected. The actual density n_0 where the reflection occurs is given by the roots of the right-hand side of (7.67). By observing the time interval between the initial transmission and reception of the reflected signal the height h_1 corresponding to that density can be found. By varying the frequency ω_1 and studying the change in time intervals the electron density as a function of height can be determined. If the frequency ω_1 is too high, the index of refraction does not vanish and very little reflection occurs. The frequency above which reflections disappear determines the maximum electron density in a given layer. A somewhat more quantitative treatment using the WKB approximation is sketched in Problem 7.9.

The behavior of $\epsilon_-(\omega)$ at low frequencies is responsible for a peculiar magnetospheric propagation phenomenon called "whistlers." As $\omega \rightarrow 0$, $\epsilon_-(\omega)$ tends to positive infinity as $\epsilon_- \approx \omega_p^2/\omega\omega_B$. Propagation occurs, but with a wave number (7.5),

$$k_- \approx \frac{\omega_p}{c} \sqrt{\frac{\omega}{\omega_B}}$$

This corresponds to a highly dispersive medium. Energy transport is governed by the group velocity (7.86)—see Section 7.8—which is

$$v_g(\omega) \approx 2v_p(\omega) \approx 2c \frac{\sqrt{\omega_B \omega}}{\omega_p}$$

Pulses of radiation at different frequencies travel at different speeds: the lower the frequency the slower the speed. A thunderstorm in one hemisphere generates a wide spectrum of radiation, some of which propagates more or less

Fig. 7.11 Electron density as a function of height in a layer of the ionosphere (schematic).

along the dipole field lines of the earth's magnetic field in a fashion described approximately by (7.67). The higher frequency components reach the antipodal point first, the lower frequency ones later. This gives rise at 10^5 Hz and below to *whistlers*, so named because the signal, as detected in an audio receiver, is a whistle-like sound beginning at high audio frequencies and falling rapidly through the audible range. With the estimates given above for ω_p and ω_B and distances of the order of 10^4 km, the reader can verify that the time scale for the whistlers is measured in seconds. Further discussion on whistlers can be found in the reading suggestions at the end of the chapter and in the problems.

7.7 Waves in a Conducting or Dissipative Medium

We have seen in Section 7.5 that the dielectric constant of a medium is generally complex, whether the material is an insulator or conductor. For insulators the imaginary part of ϵ can be neglected for many purposes, but for conductors this is far from true. The behavior of waves in conducting media is of such practical importance that we consider it separately here, even though the essentials have already been presented in Sections 7.5(a) and (c). It is customary to separate the complex dielectric constant of the conducting medium formally into two parts, a real "dielectric constant" ϵ , and a real "conductivity" σ . This separation can be viewed as merely a convenient way of exhibiting explicitly the real and imaginary parts of the dielectric constant, but it has a more intuitive basis in that the conductivity so defined is usually independent of frequency, at least for microwave and lower frequencies as already discussed.

If the fields in the conductor vary in space and time as $e^{i\mathbf{k}\cdot\mathbf{x}-i\omega t}$, the wave number k is given, according to (7.56), (7.57), and (7.5), by the complex expression

$$k^2 = \mu\epsilon \frac{\omega^2}{c^2} \left(1 + i \frac{4\pi\sigma}{\omega\epsilon} \right) \quad (7.68)$$

The first term corresponds to the displacement-current and the second to the conduction-current contribution. In taking the square root to find k the branch is chosen to give the familiar results when $\sigma=0$. Then one finds, assuming that σ , μ , and ϵ are real,

$$k = \beta + i \frac{\alpha}{2}$$

where

$$\left. \begin{matrix} \beta \\ \alpha \end{matrix} \right\} = \sqrt{\mu\epsilon} \frac{\omega}{c} \left[\frac{\sqrt{1 + \left(\frac{4\pi\sigma}{\omega\epsilon} \right)^2} \pm 1}{2} \right]^{1/2} \quad (7.69)$$

For a poor conductor ($\frac{4\pi\sigma}{\omega\epsilon} \ll 1$) we find approximately

$$k = \beta + i\frac{\alpha}{2} \approx \sqrt{\mu\epsilon} \frac{\omega}{c} + i\frac{2\pi}{c} \sqrt{\frac{\mu}{\epsilon}} \sigma \quad (7.70)$$

correct to first order in $(\sigma/\omega\epsilon)$. In this limit $\text{Re } k \gg \text{Im } k$ and the attenuation of the wave ($\text{Im } k$) is independent of frequency, aside from the possible frequency variation of the dielectric constant and conductivity. For a good conductor ($\frac{4\pi\sigma}{\omega\epsilon} \gg 1$), on the other hand, $\frac{\alpha}{2}$ and β are approximately equal:

$$k \approx (1+i) \frac{\sqrt{2\pi\omega\mu\sigma}}{c} \quad (7.71)$$

where only the lowest-order terms in $(\omega\epsilon/\sigma)$ have been kept.

The waves propagating as $\exp(i\mathbf{k} \cdot \mathbf{x} - i\omega t)$ are damped, transverse waves. The fields can be written as

$$\left. \begin{aligned} \mathbf{E} &= \mathbf{E}_0 e^{-\frac{\alpha}{2}\mathbf{n} \cdot \mathbf{x}} e^{i\beta\mathbf{n} \cdot \mathbf{x} - i\omega t} \\ \mathbf{H} &= \mathbf{H}_0 e^{-\frac{\alpha}{2}\mathbf{n} \cdot \mathbf{x}} e^{i\beta\mathbf{n} \cdot \mathbf{x} - i\omega t} \end{aligned} \right\} \quad (7.72)$$

where \mathbf{n} is a unit vector in the direction of \mathbf{k} . The divergence equation for \mathbf{E} shows that $\mathbf{E}_0 \cdot \mathbf{n} = 0$, while Faraday's law gives

$$\mathbf{H}_0 = \frac{c}{\mu\omega} \left(\beta + i\frac{\alpha}{2} \right) \mathbf{n} \times \mathbf{E}_0 \quad (7.73)$$

This shows that \mathbf{H} and \mathbf{E} are out of phase in a conductor. With the magnitude and phase of k defined as

$$\left. \begin{aligned} |k| &= \sqrt{\frac{\alpha^2}{4} + \beta^2} = \sqrt{\mu\epsilon} \frac{\omega}{c} \left[1 + \left(\frac{4\pi\sigma}{\omega\epsilon} \right)^2 \right]^{1/4} \\ \phi &= \tan^{-1} \frac{\alpha}{2\beta} = \frac{1}{2} \tan^{-1} \left(\frac{4\pi\sigma}{\omega\epsilon} \right) \end{aligned} \right\} \quad (7.74)$$

we can write (7.73) in the form:

$$\mathbf{H}_0 = \sqrt{\frac{\epsilon}{\mu}} \left[1 + \left(\frac{4\pi\sigma}{\omega\epsilon} \right)^2 \right]^{1/4} e^{i\phi} \mathbf{n} \times \mathbf{E}_0 \quad (7.75)$$

The interpretation of (7.75) is that \mathbf{H} lags \mathbf{E} in time by the phase angle ϕ and has a relative amplitude:

$$\frac{|\mathbf{H}_0|}{|\mathbf{E}_0|} = \sqrt{\frac{\epsilon}{\mu}} \left[1 + \left(\frac{4\pi\sigma}{\omega\epsilon} \right)^2 \right]^{1/4} \quad (7.76)$$

In very good conductors we see that the magnetic field is very large compared to the electric field and lags in phase by almost 45° . The field energy is almost entirely magnetic in nature.

The waves given by (7.72) show an exponential damping with distance. This means that an electromagnetic wave entering a conductor is damped to $1/e = 0.369$ of its initial amplitude in a distance:

$$\delta = \frac{2}{\alpha} \approx \frac{c}{\sqrt{2\pi\mu\omega\sigma}} \quad (7.77)$$

the last form being the approximation for good conductors. The distance δ is called the *skin depth* or the *penetration depth*.^{*} For a conductor like copper, $\delta \approx 0.85$ cm for frequencies of 60 cps, and $\delta \approx 0.71 \times 10^{-3}$ cm for 100 Mc/sec. This rapid attenuation of waves means that in high-frequency circuits current flows only on the surface of the conductors. One simple consequence is that the high-frequency inductance of circuit elements is somewhat smaller than the low-frequency inductance because of the expulsion of flux from the interior of the conductors.

The problem of reflection and refraction at an interface between conducting media is rather complicated in detail and will not be treated here. The interested reader may refer to *Stratton*, pp. 500 ff. for a discussion of this point. We only observe that, in the notation of Section 7.3, the refracted wave has spatial variation,

$$e^{i\mathbf{k}' \cdot \mathbf{x}} = e^{i(k' \sin \tau)x + i(k' \cos \tau)z}$$

where the x direction is parallel to the surface and the z direction is normal to it. Using Snell's law this can be written

$$e^{i\mathbf{k}' \cdot \mathbf{x}} = e^{i(k \sin i)x + i\sqrt{k'^2 - k^2 \sin^2 i}z}$$

In a dissipative medium k'^2 is complex [given by (7.68)] and so the coefficient of z is complex. The wave is attenuated in the z direction. For a good conductor, where (7.71) holds, $|k'^2| \gg k^2$ and the exponential is given approximately by

$$e^{i\mathbf{k}' \cdot \mathbf{x}} \approx e^{-z/\delta} e^{i[(k \sin i)x + z/\delta]} \quad (7.78)$$

Equation (7.78) represents an inhomogeneous plane wave, alluded to at the end of Section 7.1, with the surfaces of constant amplitude parallel to the surface of the conductor and the surfaces of constant phase inclined only slightly away from this, at an angle $(k\delta \sin i)$ to the surface. In Section 8.1 this problem is examined again in more detail.

^{*} For reference, the skin depth (7.77) appears in MKSA units as $\delta = (2/\mu\omega\sigma)^{1/2}$.

7.8 Superposition of Waves in One Dimension, Group Velocity

In the previous sections plane-wave solutions to the Maxwell equations were found and their properties discussed. Only monochromatic waves, those with a definite frequency and wave number, were treated. In actual circumstances such idealized solutions do not arise. Even in the most monochromatic light source or the most sharply tuned radio transmitter or receiver, one deals with a finite (although perhaps small) spread of frequencies or wavelengths. This spread may originate in the finite duration of a pulse, in inherent broadening in the source, or in many other ways. Since the basic equations are linear, it is in principle an elementary matter to make the appropriate linear superposition of solutions with different frequencies. In general, however, there are several new features which arise.

1. If the medium is dispersive (i.e., the dielectric constant is a function of the frequency of the fields), the phase velocity is not the same for each frequency component of the wave. Consequently different components of the wave travel with different speeds and tend to change phase with respect to one another.
2. In a dispersive medium the velocity of energy flow may differ greatly from the phase velocity, or may even lack precise meaning.
3. In a dissipative medium, a pulse of radiation will be attenuated as it travels with or without distortion, depending on whether the dissipative effects are or are not sensitive functions of frequency.

The essentials of these dispersive and dissipative effects are implicit in the ideas of Fourier series and integrals (Section 2.8). For simplicity, we consider scalar waves in only one dimension. The scalar amplitude $u(x, t)$ can be thought of as one of the components of the electromagnetic field. The basic solution to the wave equation (7.2) has been exhibited in (7.6). The relationship between frequency ω and wave number k is given by (7.5) for the electromagnetic field. Either ω or k can be viewed as the independent variable when one considers making a linear superposition. Initially we will find it most convenient to use k as an independent variable. To allow for the possibility of dispersion we will consider ω as a general function of k :

$$\omega = \omega(k) \quad (7.79)$$

Since the dispersive properties cannot depend on whether the wave travels to the left or to the right, ω must be an even function of k , $\omega(-k) = \omega(k)$. For most wavelengths ω is a smoothly varying function of k . But, as we have seen in Section 7.5, at certain frequencies there are regions of "anomalous dispersion" where ω varies rapidly over a narrow interval of wavelengths. With the general form (7.79), our subsequent discussion can apply equally well to electromagnetic waves, sound waves, de Broglie matter waves, etc. For the present we assume that k and $\omega(k)$ are real, and so exclude dissipative effects.

From the basic solutions (7.6) we can build up a general solution of the form

$$u(x, t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} A(k) e^{ikx - i\omega(k)t} dk \quad (7.80)$$

The factor $1/\sqrt{2\pi}$ has been inserted to conform with the Fourier integral notation of (2.44) and (2.45). The amplitude $A(k)$ describes the properties of the linear superposition of the different waves. It is given by the transform of the spatial amplitude $u(x, t)$, evaluated at $t=0$.*

$$A(k) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} u(x, 0) e^{-ikx} dx \quad (7.81)$$

If $u(x, 0)$ represents a harmonic wave $e^{ik_0 x}$ for all x , the orthogonality relation (2.46) shows that $A(k) = \sqrt{2\pi} \delta(k - k_0)$, corresponding to a monochromatic traveling wave $u(x, t) = e^{ik_0 x - i\omega(k_0)t}$, as required. If, however, at $t=0$, $u(x, 0)$ represents a finite wave train with a length of order Δx , as shown in Fig. 7.12, then the amplitude $A(k)$ is not a delta function. Rather, it is a peaked function with a breadth of the order of Δk , centered around a wave number k_0 which is the dominant wave number in the modulated wave $u(x, 0)$. If Δx and Δk are defined as the rms deviations from the average values of x and k [defined in

Fig. 7.12 A harmonic wave train of finite extent and its Fourier spectrum in wave number.

* The following discussion slights somewhat the initial-value problem. For a second-order differential equation we must specify not only $u(x, 0)$ but also $\partial u(x, 0)/\partial t$. This omission is of no consequence for the rest of the material in this section. It is remedied in the following section.

terms of the intensities $|u(x, 0)|^2$ and $|A(k)|^2$, it is possible to draw the general conclusion:

$$\Delta x \Delta k \geq \frac{1}{2} \quad (7.82)$$

The reader may readily verify that, for most reasonable pulses or wave packets which do not cut off too violently, Δx times Δk lies near the lower limiting value in (7.82). This means that short wave trains with only a few wavelengths present have a very wide distribution of wave numbers of monochromatic waves, and conversely that long sinusoidal wave trains are almost monochromatic. Relation (7.82) applies equally well to distributions in time and in frequency.

The next question is the behavior of a pulse or finite wave train in time. The pulse shown at $t=0$ in Fig. 7.12 begins to move as time goes on. The different frequency or wave-number components in it move at different phase velocities. Consequently there is a tendency for the original coherence to be lost and for the pulse to become distorted in shape. At the very least, we might expect it to propagate with a rather different velocity from, say, the average phase velocity of its component waves. The general case of a highly dispersive medium or a very sharp pulse with a great spread of wave numbers present is difficult to treat. But the propagation of a pulse which is not too broad in its wave-number spectrum, or a pulse in a medium for which the frequency depends weakly on wave number, can be handled in the following approximate way. The wave at time t is given by (7.80). If the distribution $A(k)$ is fairly sharply peaked around some value k_0 , then the frequency $\omega(k)$ can be expanded around that value of k :

$$\omega(k) = \omega_0 + \left. \frac{d\omega}{dk} \right|_0 (k - k_0) + \cdots \quad (7.83)$$

and the integral performed. Thus

$$u(x, t) \approx \frac{e^{i[k_0(d\omega/dk)|_0 - \omega_0]t}}{\sqrt{2\pi}} \int_{-\infty}^{\infty} A(k) e^{i[x - (d\omega/dk)|_0 t]k} dk \quad (7.84)$$

From (7.81) and its inverse it is apparent that the integral in (7.84) is just $u(x', 0)$, where $x' = x - (d\omega/dk)|_0 t$:

$$u(x, t) \approx u\left(x - \left. \frac{d\omega}{dk} \right|_0 t, 0\right) e^{i[k_0(d\omega/dk)|_0 - \omega_0]t} \quad (7.85)$$

This shows that, apart from an overall phase factor, the pulse travels along undistorted in shape with a velocity, called the *group velocity*:

$$v_g = \left. \frac{d\omega}{dk} \right|_0 \quad (7.86)$$

If an energy density is associated with the magnitude of the wave (or its absolute square), it is clear that in this approximation the transport of energy occurs with the group velocity, since that is the rate at which the pulse travels along.

For light waves the relation between ω and k is given by

$$\omega(k) = \frac{ck}{n(k)} \quad (7.87)$$

where c is the velocity of light in vacuum, and $n(k)$ is the index of refraction expressed as a function of k . The phase velocity is

$$v_p = \frac{\omega(k)}{k} = \frac{c}{n(k)} \quad (7.88)$$

and is greater or smaller than c depending on whether $n(k)$ is smaller or larger than unity. For most optical wavelengths $n(k)$ is greater than unity in almost all substances. The group velocity (7.86) is

$$v_g = \frac{c}{[n(\omega) + \omega(dn/d\omega)]} \quad (7.89)$$

In this equation it is more convenient to think of n as a function of ω than of k . For normal dispersion $(dn/d\omega) > 0$, and also $n > 1$; then the velocity of energy flow is less than the phase velocity and also less than c . In regions of anomalous dispersion, however, $dn/d\omega$ can become large and negative as can be inferred from Fig. 7.8. Then the group velocity differs greatly from the phase velocity, often becoming larger than c .* The behavior of group and phase velocities as a

Fig. 7.13 Index of refraction $n(\omega)$ as a function of frequency ω at a region of anomalous dispersion; phase velocity v_p and group velocity v_g as functions of ω .

* There is no cause for alarm that our ideas of special relativity are violated; group velocity is just not a useful concept here. A large value of $dn/d\omega$ is equivalent to a rapid variation of ω as a function of k . Consequently the approximations made in (7.83) ff. are no longer valid. The behavior of the pulse is much more involved.

function of frequency in the neighborhood of a region of anomalous dispersion is shown in Fig. 7.13.

7.9 Illustration of the Spreading of a Pulse as It Propagates in a Dispersive Medium

To illustrate the ideas of the previous section and to show the validity of the concept of group velocity we will now consider a specific model for the dependence of frequency on wave number and will calculate without approximations the propagation of a pulse in this model medium. Before specifying the particular model it is necessary to state the initial-value problem in more detail than was done in (7.80) and (7.81). As noted there, the proper specification of an initial-value problem for the wave equation demands the initial values of both function $u(x, 0)$ and time derivative $\partial u(x, 0)/\partial t$. If we agree to take the real part of (7.80) to obtain $u(x, t)$,

$$u(x, t) = \frac{1}{2} \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} A(k) e^{ikx - i\omega(k)t} dk + \text{c.c.} \quad (7.90)$$

then it is easy to show that $A(k)$ is given in terms of the initial values by:

$$A(k) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-ikx} \left[u(x, 0) + \frac{i}{\omega(k)} \frac{\partial u}{\partial t}(x, 0) \right] dx \quad (7.91)$$

We will take a Gaussian modulated oscillation

$$u(x, 0) = e^{-x^2/2L^2} \cos k_0 x \quad (7.92)$$

as the initial shape of the pulse. For simplicity, we will assume that

$$\frac{\partial u}{\partial t}(x, 0) = 0 \quad (7.93)$$

This means that at times immediately before $t=0$ the wave consisted of two pulses, both moving towards the origin, such that at $t=0$ they coalesced into the shape given by (7.92). Clearly at later times we expect each pulse to re-emerge on the other side of the origin. Consequently the initial distribution (7.92) may be expected to split into two identical packets, one moving to the left and one to the right. The Fourier amplitude $A(k)$ for the pulse described by (7.92) and (7.93) is:

$$\begin{aligned} A(k) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-ikx} e^{-x^2/2L^2} \cos k_0 x dx \\ &= \frac{L}{2} [e^{-(L^2/2)(k-k_0)^2} + e^{-(L^2/2)(k+k_0)^2}] \end{aligned} \quad (7.94)$$

The symmetry $A(-k) = A(k)$ is a reflection of the presence of two pulses traveling away from the origin, as will be seen below.

In order to calculate the wave form at later times we must specify $\omega = \omega(k)$. As a model allowing exact calculation and showing the essential dispersive effects, we assume

$$\omega(k) = \nu \left(1 + \frac{a^2 k^2}{2} \right) \quad (7.95)$$

where ν is a constant frequency, and a is a constant length which is a typical wavelength where dispersive effects become important. Equation (7.95) is an approximation to the dispersion equation of the tenuous plasma, (7.59) or (7.61). Since the pulse (7.92) is a modulated wave of wave number $k = k_0$, the approximate arguments of the preceding section imply that the two pulses will travel with the group velocity

$$v_g = \frac{d\omega}{dk}(k_0) = \nu a^2 k_0 \quad (7.96)$$

and will be essentially unaltered in shape provided the pulse is not too narrow in space.

The exact behavior of the wave as a function of time is given by (7.90), with (7.94) for $A(k)$:

$$u(x, t) = \frac{L}{2\sqrt{2\pi}} \operatorname{Re} \int_{-\infty}^{\infty} \left[e^{-(L^2/2)(k-k_0)^2} + e^{-(L^2/2)(k+k_0)^2} \right] e^{ikx - i\nu t [1 + (a^2 k^2/2)]} dk \quad (7.97)$$

The integrals can be performed by appropriately completing the squares in the exponents. The result is

$$u(x, t) = \frac{1}{2} \operatorname{Re} \left\{ \frac{\exp \left[-\frac{(x - \nu a^2 k_0 t)^2}{2L^2 \left(1 + \frac{ia^2 \nu t}{L^2} \right)} \right]}{\left(1 + \frac{ia^2 \nu t}{L^2} \right)^{1/2}} \exp \left[ik_0 x - i\nu \left(1 + \frac{a^2 k_0^2}{2} \right) t \right] + (k_0 \rightarrow -k_0) \right\} \quad (7.98)$$

Equation (7.98) represents two pulses traveling in opposite directions. The peak amplitude of each pulse travels with the group velocity (7.96), while the modulation envelope remains Gaussian in shape. The width of the Gaussian is not constant, however, but increases with time. The width of the envelope is

$$L(t) = \left[L^2 + \left(\frac{a^2 \nu t}{L} \right)^2 \right]^{1/2} \quad (7.99)$$

Thus the dispersive effects on the pulse are greater (for a given elapsed time), the

sharper the envelope. The criterion for a small change in shape is that $L \gg a$. Of course, at long times the width of the Gaussian increases linearly with time

$$L(t) \rightarrow \frac{a^2 vt}{L} \quad (7.100)$$

but the time of attainment of this asymptotic form depends on the ratio (L/a) . A measure of how rapidly the pulse spreads is provided by a comparison of $L(t)$ given by (7.99), with $v_g t = \nu a^2 k_0 t$. Figure 7.14 shows two examples of curves of the position of peak amplitude ($v_g t$) and the positions $v_g t \pm L(t)$, which indicate the spread of the pulse, as functions of time. On the left the pulse is not too narrow compared to the wavelength k_0^{-1} and so does not spread too rapidly. The pulse on the right, however, is so narrow initially that it is very rapidly spread out and scarcely represents a pulse after a short time.

Although the above results have been derived for a special choice (7.92) of initial pulse shape and dispersion relation (7.95), their implications are of a more general nature. We have seen in Section 7.8 that the average velocity of a pulse is the group velocity $v_g = d\omega/dk = \omega'$. The spreading of the pulse can be accounted for by noting that a pulse with an initial spatial width Δx_0 must have inherent in it a spread of wave numbers $\Delta k \sim (1/\Delta x_0)$. This means that the group velocity, when evaluated for various k values within the pulse, has a spread in it of the order

$$\Delta v_g \sim \omega'' \Delta k \sim \frac{\omega''}{\Delta x_0} \quad (7.101)$$

At a time t this implies a spread in position of the order of $\Delta v_g t$. If we combine the uncertainties in position by taking the square root of the sum of squares, we

Fig. 7.14 Change in shape of a wave packet as it travels along. The broad packet, containing many wavelengths ($k_0 L \gg 1$), is distorted comparatively little, while the narrow packet ($k_0 L \lesssim 1$) broadens rapidly.

obtain the width $\Delta x(t)$ at time t :

$$\Delta x(t) = \sqrt{(\Delta x_0)^2 + \left(\frac{\omega'' t}{\Delta x_0}\right)^2} \quad (7.102)$$

We note that (7.102) agrees exactly with (7.99) if we put $\Delta x_0 = L$. The expression (7.102) for $\Delta x(t)$ shows the general result that, if $\omega'' \neq 0$, a narrow pulse spreads rapidly because of its broad spectrum of wave numbers, and vice versa. All these ideas carry over immediately into wave mechanics. They form the basis of the Heisenberg uncertainty principle. In wave mechanics, the frequency is identified with energy divided by Planck's constant, while wave number is momentum divided by Planck's constant.

The problem of wave packets in a dissipative, as well as dispersive, medium is rather complicated. Certain aspects can be discussed analytically, but the analytical expressions are not readily interpreted physically. Wave packets are attenuated and distorted appreciably as they propagate. The reader may refer to *Stratton* pp. 301–309, for a discussion of the problem, including numerical examples.

7.10 Causality in the Connection Between \mathbf{D} and \mathbf{E} , Kramers-Kronig Relations

(a) Nonlocality in Time

Another consequence of the frequency dependence of $\epsilon(\omega)$ is a temporally nonlocal connection between the displacement $\mathbf{D}(\mathbf{x}, t)$ and the electric field $\mathbf{E}(\mathbf{x}, t)$. If the monochromatic components of frequency ω are related by

$$\mathbf{D}(\mathbf{x}, \omega) = \epsilon(\omega) \mathbf{E}(\mathbf{x}, \omega) \quad (7.103)$$

the dependence on time can be constructed by Fourier superposition. Treating the spatial coordinate as a parameter, the Fourier integrals in time and frequency can be written

$$\mathbf{D}(\mathbf{x}, t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \mathbf{D}(\mathbf{x}, \omega) e^{-i\omega t} d\omega$$

and

$$\mathbf{D}(\mathbf{x}, \omega) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \mathbf{D}(\mathbf{x}, t') e^{i\omega t'} dt' \quad (7.104)$$

with corresponding equations for \mathbf{E} . The substitution of (7.103) for $\mathbf{D}(\mathbf{x}, \omega)$ gives

$$\mathbf{D}(\mathbf{x}, t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \epsilon(\omega) \mathbf{E}(\mathbf{x}, \omega) e^{-i\omega t} d\omega$$

We now insert the Fourier representation of $\mathbf{E}(\mathbf{x}, \omega)$ into the integral and obtain

$$\mathbf{D}(\mathbf{x}, t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} d\omega \epsilon(\omega) e^{-i\omega t} \int_{-\infty}^{\infty} dt' e^{i\omega t'} \mathbf{E}(\mathbf{x}, t')$$

With the assumption that the orders of integration can be interchanged, the last expression can be written as

$$\mathbf{D}(\mathbf{x}, t) = \mathbf{E}(\mathbf{x}, t) + \int_{-\infty}^{\infty} G(\tau) \mathbf{E}(\mathbf{x}, t - \tau) d\tau \quad (7.105)$$

where $G(\tau)$ is the Fourier transform of $4\pi\chi_e = \epsilon(\omega) - 1$:

$$G(\tau) = \frac{1}{2\pi} \int_{-\infty}^{\infty} [\epsilon(\omega) - 1] e^{-i\omega\tau} d\omega \quad (7.106)$$

Equation (7.105) and (7.106) give a nonlocal connection between \mathbf{D} and \mathbf{E} , in which \mathbf{D} at time t depends on the electric field at times other than t .^{*} If $\epsilon(\omega)$ is independent of ω for all ω , (7.106) yields $G(\tau) \propto \delta(\tau)$ and the instantaneous connection is obtained, but if $\epsilon(\omega)$ varies with ω , $G(\tau)$ is nonvanishing for some values of τ different from zero.

(b) *Simple Model for $G(\tau)$, Limitations*

To illustrate the character of the connection implied by (7.105) and (7.106) we consider a one-resonance version of the index of refraction (7.51):

$$\epsilon(\omega) - 1 = \omega_p^2 (\omega_0^2 - \omega^2 - i\gamma\omega)^{-1} \quad (7.107)$$

The susceptibility kernel $G(\tau)$ for this model of $\epsilon(\omega)$ is

$$G(\tau) = \frac{\omega_p^2}{2\pi} \int_{-\infty}^{\infty} \frac{e^{-i\omega\tau}}{\omega_0^2 - \omega^2 - i\gamma\omega} d\omega \quad (7.108)$$

The integral can be evaluated by contour integration. The integrand has poles in the lower half ω plane at

$$\omega_{1,2} = -\frac{i\gamma}{2} \pm \nu_0, \quad \text{where } \nu_0^2 = \omega_0^2 - \frac{\gamma^2}{4} \quad (7.109)$$

^{*} Equations (7.103) and (7.105) are recognizable as an example of the *faltung* theorem of Fourier integrals: if $A(t)$, $B(t)$, $C(t)$ and $a(\omega)$, $b(\omega)$, $c(\omega)$ are two sets of functions related in pairs by the Fourier inversion formulas (7.104), and

$$c(\omega) = a(\omega)b(\omega)$$

then, under suitable restrictions concerning integrability,

$$C(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} A(t') B(t - t') dt'$$

For $\tau < 0$ the contour can be closed in the upper half plane without affecting the value of the integral. Since the integrand is regular inside the closed contour the integral vanishes. For $\tau > 0$, the contour is closed in the lower half-plane and the integral is given by $-2\pi i$ times the residues at the two poles. The kernel (7.108) is therefore

$$G(\tau) = \omega_p^2 e^{-\gamma\tau/2} \frac{\sin \nu_0\tau}{\nu_0} \theta(\tau) \quad (7.110)$$

where $\theta(\tau)$ is the step function [$\theta(\tau) = 0$ for $\tau < 0$; $\theta(\tau) = 1$ for $\tau > 0$]. For the dielectric constant (7.51) the kernel $G(\tau)$ is just a linear superposition of terms like (7.110). The kernel $G(\tau)$ is oscillatory with the characteristic frequency of the medium and damped in time with the damping constant of the electronic oscillators. The nonlocality in time of the connection between \mathbf{D} and \mathbf{E} is thus confined to times of the order of γ^{-1} . Since γ is the width in frequency of spectral lines and these are typically 10^7 – 10^9 sec^{-1} , the departure from simultaneity is of the order of 10^{-7} – 10^{-9} sec . For frequencies above the microwave region many cycles of the electric field oscillations contribute an average weighed by $G(\tau)$ to the displacement \mathbf{D} at a given instant of time.

Equation (7.105) is nonlocal in time, but not in space. This approximation is valid provided the spatial variation of the applied fields has a scale that is large compared with the dimensions involved in the creation of the atomic or molecular polarization. For bound charges the latter scale is of the order of atomic dimensions or less, and so the concept of a dielectric constant that is a function only of ω can be expected to hold for frequencies well beyond the visible range. For conductors, however, the presence of free charges with macroscopic mean free paths makes the assumption of a simple $\epsilon(\omega)$ or $\sigma(\omega)$ break down at much lower frequencies. For a good conductor like copper we have seen that the damping constant (corresponding to a collision frequency) is of the order of $\gamma_0 \sim 3 \times 10^{13} \text{ sec}^{-1}$ at room temperature. At liquid helium temperatures, the damping constant may be 10^{-3} times the room temperature value. Taking the Bohr velocity in hydrogen ($c/137$) as typical of electron velocities in metals, we find mean free paths of the order of $L \sim c/(137\gamma_0) \sim 10^{-2} \text{ cm}$ at liquid helium temperatures. On the other hand, the conventional skin depth δ (7.77) can be much smaller, of the order of 10^{-5} or 10^{-6} cm at microwave frequencies. In such circumstances, Ohm's law must be replaced by a nonlocal expression. The conductivity becomes a tensorial quantity depending on wave number \mathbf{k} and frequency ω . The associated departures from the standard behavior are known collectively as the *anomalous skin effect*. They can be utilized to map out the Fermi surfaces in metals.* Similar nonlocal effects occur

* A. B. Pippard, in *Reports on Progress in Physics* **33**, 176 (1960), and the article entitled "The Dynamics of Conduction Electrons," by the same author in *Low-Temperature Physics*, Les Houches 1961, eds., C. de Witt, B. Dreyfus, and P. G. de Gennes, Gordon and Breach, New York (1962). The latter article has been issued separately by the same publisher.

in superconductors where the electromagnetic properties involve a coherence length of the order of 10^{-4} cm.* With this brief mention of the limitations of (7.105) and the areas where generalizations have been fruitful we return to the discussion of the physical content of (7.105).

(c) *Causality and Analyticity Domain of $\epsilon(\omega)$*

The most obvious and fundamental feature of the kernel (7.110) is that it vanishes for $\tau < 0$. This means that at time t only values of the electric field *prior* to that time enter in determining the displacement, in accord with our fundamental ideas of causality in physical phenomena. Equation (7.105) can thus be written

$$\mathbf{D}(\mathbf{x}, t) = \mathbf{E}(\mathbf{x}, t) + \int_0^\infty G(\tau) \mathbf{E}(\mathbf{x}, t - \tau) d\tau \quad (7.111)$$

This is, in fact, the most general spatially local, linear, and causal relation that can be written between \mathbf{D} and \mathbf{E} in a uniform isotropic medium. Its validity transcends any specific model of $\epsilon(\omega)$. From (7.106) the dielectric constant can be expressed in terms of $G(\tau)$ as

$$\epsilon(\omega) = 1 + \int_0^\infty G(\tau) e^{i\omega\tau} d\tau \quad (7.112)$$

This relation has several interesting consequences. From the reality of \mathbf{D} , \mathbf{E} , and therefore $G(\tau)$ in (7.111) we can deduce from (7.112) that for complex ω ,

$$\epsilon(-\omega) = \epsilon^*(\omega^*) \quad (7.113)$$

Furthermore, if (7.112) is viewed as a representation of $\epsilon(\omega)$ in the complex ω plane, it shows that $\epsilon(\omega)$ is an analytic function of ω in the upper half plane, provided $G(\tau)$ is finite for all τ . On the real axis it is necessary to invoke the “physically reasonable” requirement that $G(\tau) \rightarrow 0$ as $\tau \rightarrow \infty$ to assure that $\epsilon(\omega)$ is also analytic there. This is true for dielectrics, but not for conductors, where $G(\tau) \rightarrow 4\pi\sigma$ as $\tau \rightarrow \infty$ and $\epsilon(\omega)$ has a simple pole at $\omega = 0$ ($\epsilon \rightarrow i4\pi\sigma/\omega$ as $\omega \rightarrow 0$). Apart, then, from a possible pole at $\omega = 0$, the dielectric constant $\epsilon(\omega)$ is analytic in ω for $\text{Im } \omega \geq 0$ as a direct result of the causal relation (7.111) between \mathbf{D} and \mathbf{E} . These properties can be verified, of course, for the models discussed in Sections 7.5(a) and 7.5(c).

The behavior of $\epsilon(\omega) - 1$ for large ω can be related to the behavior of $G(\tau)$ at small times. A Taylor series expansion of G in (7.112) leads to the asymptotic series,

$$\epsilon(\omega) - 1 \approx \frac{iG(0)}{\omega} - \frac{G'(0)}{\omega^2} + \dots$$

* See, for example, the article “Superconductivity,” by M. Tinkham in the book, *Low Temperature Physics*, cited above.

where the argument of G and its derivatives is $\tau=0^+$. It is unphysical to have $G(0^-)=0$, but $G(0^+)\neq 0$. Thus the first term in the series is absent, and $\epsilon(\omega)-1$ falls off at high frequencies as ω^{-2} , just as was found in (7.59) for the oscillator model. The asymptotic series shows, in fact, that the real and imaginary parts of $\epsilon(\omega)-1$ behave for large real ω as

$$\operatorname{Re} [\epsilon(\omega)-1]=0\left(\frac{1}{\omega^2}\right), \quad \operatorname{Im} \epsilon(\omega)=0\left(\frac{1}{\omega^3}\right) \quad (7.114)$$

These asymptotic forms depend only upon the possibility of a Taylor series expansion of $G(\tau)$ around $\tau=0^+$.

(d) *Kramers-Kronig Relations*

The analyticity of $\epsilon(\omega)$ in the upper half ω plane permits the use of Cauchy's theorem to relate the real and imaginary part of $\epsilon(\omega)$ on the real axis. For any point z inside a closed contour C in the upper half ω plane, Cauchy's theorem gives

$$\epsilon(z)=1+\frac{1}{2\pi i} \oint_C \frac{[\epsilon(\omega')-1]}{\omega'-z} d\omega'$$

The contour C is now chosen to consist of the real ω axis and a great semicircle at infinity in the upper half plane. From the asymptotic expansion just discussed or the specific results of Section 7.5(d), we see that $\epsilon-1$ vanishes sufficiently rapidly at infinity so that there is no contribution to the integral from the great semicircle. Thus the Cauchy integral can be written

$$\epsilon(z)=1+\frac{1}{2\pi i} \int_{-\infty}^{\infty} \frac{[\epsilon(\omega')-1]}{\omega'-z} d\omega' \quad (7.115)$$

where z is now any point in the upper half plane and the integral is taken along the real axis. Taking the limit as the complex frequency approaches the real axis from above, we write $z=\omega+i\epsilon$ in (7.115):

$$\epsilon(\omega)=1+\frac{1}{2\pi i} \int_{-\infty}^{\infty} \frac{[\epsilon(\omega')-1]}{\omega'-\omega-i\epsilon} d\omega' \quad (7.116)$$

For real ω the presence of the $i\epsilon$ in the denominator is a mnemonic for the distortion of the contour along the real axis by giving it a infinitesimal semicircular detour *below* the point $\omega'=\omega$. The denominator can be written formally as

$$\frac{1}{\omega'-\omega-i\epsilon}=P\left(\frac{1}{\omega'-\omega}\right)+\pi i\delta(\omega'-\omega) \quad (7.117)$$

where P means principal part. The delta function serves to pick up the contribution from the small semicircle going in a positive sense halfway around

the pole at $\omega' = \omega$. Use of (7.117) and a simple rearrangement turns (7.116) into

$$\epsilon(\omega) = 1 + \frac{1}{\pi i} P \int_{-\infty}^{\infty} \frac{[\epsilon(\omega') - 1]}{\omega' - \omega} d\omega' \quad (7.118)$$

The real and imaginary parts of this equation are

$$\begin{aligned} \operatorname{Re} \epsilon(\omega) &= 1 + \frac{1}{\pi} P \int_{-\infty}^{\infty} \frac{\operatorname{Im} \epsilon(\omega')}{\omega' - \omega} d\omega' \\ \operatorname{Im} \epsilon(\omega) &= -\frac{1}{\pi} P \int_{-\infty}^{\infty} \frac{[\operatorname{Re} \epsilon(\omega') - 1]}{\omega' - \omega} d\omega' \end{aligned} \quad (7.119)$$

These relations, or the ones recorded immediately below, are called *Kramers-Kronig relations* or *dispersion relations*. They were first derived by H. A. Kramers (1927) and R. de L. Kronig (1926) independently. The symmetry property (7.113) shows that $\operatorname{Re} \epsilon(\omega)$ is even in ω , while $\operatorname{Im} \epsilon(\omega)$ is odd. The integrals in (7.119) can thus be transformed to span only positive frequencies:

$$\begin{aligned} \operatorname{Re} \epsilon(\omega) &= 1 + \frac{2}{\pi} P \int_0^{\infty} \frac{\omega' \operatorname{Im} \epsilon(\omega')}{\omega'^2 - \omega^2} d\omega' \\ \operatorname{Im} \epsilon(\omega) &= -\frac{2\omega}{\pi} P \int_0^{\infty} \frac{[\operatorname{Re} \epsilon(\omega') - 1]}{\omega'^2 - \omega^2} d\omega' \end{aligned} \quad (7.120)$$

In writing (7.119) and (7.120) we have tacitly assumed that $\epsilon(\omega)$ was regular at $\omega = 0$. For conductors the simple pole at $\omega = 0$ can be exhibited separately with little further complication.

The Kramer-Kronig relations are of very general validity, following from little more than the assumption of the causal connection (7.111) between the polarization and the electric field. Empirical knowledge of $\operatorname{Im} \epsilon(\omega)$ from absorption studies allows the calculation of $\operatorname{Re} \epsilon(\omega)$ from the first equation in (7.120). The connection between absorption and anomalous dispersion, shown in Fig. 7.8, is contained in the relations. The presence of a very narrow absorption line or band at $\omega = \omega_0$ can be approximated by taking

$$\operatorname{Im} \epsilon(\omega') \approx \frac{\pi K}{2\omega_0} \delta(\omega' - \omega_0) + \dots$$

where K is a constant and the dots indicated the other (smoothly varying) contributions to $\operatorname{Im} \epsilon$. The first equation in (7.120) then yields

$$\operatorname{Re} \epsilon(\omega) \approx \bar{\epsilon} + \frac{K}{\omega_0^2 - \omega^2} \quad (7.121)$$

for the behavior of $\operatorname{Re} \epsilon(\omega)$ near, but not exactly at, $\omega = \omega_0$. The term $\bar{\epsilon}$ represents the slowly varying part of $\operatorname{Re} \epsilon$ resulting from the more remote contributions to $\operatorname{Im} \epsilon$. The approximation (7.121) exhibits the rapid variation of $\operatorname{Re} \epsilon(\omega)$ in the neighborhood of an absorption line, shown in Fig. 7.8 for lines of

finite width. A more realistic description for $\text{Im } \epsilon$ would lead to an expression for $\text{Re } \epsilon$ in complete accord with the behavior shown in Fig. 7.8. The demonstration of this is left to the problems at the end of the chapter.

Relations of the general type (7.119) or (7.120) connecting the dispersive and absorptive aspects of a process are extremely useful in all areas of physics. Their widespread application stems from the very small number of physically well-founded assumptions necessary for their derivation. References to their application in particle physics, as well as solid-state physics, are given at the end of the chapter. We end with mention of two *sum rules* obtainable from (7.120). It was shown in Section 7.5(d), within the context of a specific model, that the dielectric constant is given at high frequencies by (7.59). The form of (7.59) is, in fact, quite general, as was shown at the end of part (c). The plasma frequency can therefore be *defined* by means of (7.59) as

$$\omega_p^2 = \lim_{\omega \rightarrow \infty} \{\omega^2 [1 - \epsilon(\omega)]\}$$

Provided the falloff of $\text{Im } \epsilon(\omega)$ at high frequencies is given by (7.114), the first Kramers-Kronig relation yields a *sum rule* for ω_p^2 :

$$\omega_p^2 = \frac{2}{\pi} \int_0^\infty \omega \text{Im } \epsilon(\omega) d\omega \quad (7.122)$$

This relation is sometimes known as the sum rule for oscillator strengths. It can be shown to be equivalent to (7.52) for the dielectric constant (7.51), but is obviously more general.

The second sum rule concerns the integral over the real part of $\epsilon(\omega)$ and follows from the second relation (7.120). With the assumption that $[\text{Re } \epsilon(\omega') - 1] = -\omega_p^2/\omega'^2 + O(1/\omega'^4)$ for all $\omega' > N$, it is straightforward to show that for $\omega > N$

$$\text{Im } \epsilon(\omega) = \frac{2}{\pi\omega} \left\{ -\frac{\omega_p^2}{N} + \int_0^N [\text{Re } \epsilon(\omega') - 1] d\omega' \right\} + O\left(\frac{1}{\omega^3}\right)$$

It was shown in part (c) that, excluding conductors and barring the unphysical happening that $G(0^+) \neq 0$, $\text{Im } \epsilon(\omega)$ behaves at large frequencies as ω^{-3} . It therefore follows that the expression in curly brackets must vanish. We are thus led to a *second sum rule*,

$$\frac{1}{N} \int_0^N \text{Re } \epsilon(\omega) d\omega = 1 + \frac{\omega_p^2}{N^2} \quad (7.123)$$

which, for $N \rightarrow \infty$, states that the average value of $\text{Re } \epsilon(\omega)$ over all frequencies is equal to unity. For conductors, the plasma frequency sum rule (7.122) still holds, but the second sum rule (sometimes called a *superconvergence relation*) has an added term $-2\pi^2\sigma(0)/N$, on the right hand side (see Problem 7.15). These optical sum rules and several others are discussed by Altarelli et al.*

7.11 Arrival of a Signal After Propagation Through a Dispersive Medium

Some of the effects of dispersion have been considered in the previous sections. There remains one important aspect, the actual arrival at a remote point of a wave train that initially has a well-defined beginning. How does the signal build up? If the phase velocity or group velocity is greater than the velocity of light in vacuum for important frequency components, does the signal propagate faster than allowed by causality and relativity? Can the arrival time of the disturbance be given an unambiguous definition? These questions were examined authoritatively by Sommerfeld and Brillouin in papers published in *Annalen der Physik* in 1914.* The original papers, plus subsequent work by Brillouin, are contained in English translation in the book, *Wave Propagation and Group Velocity*, by Brillouin. A briefer account is given in Sommerfeld's *Optics*, Chapter III. A complete discussion is lengthy and technically complicated. We treat the qualitative features and the main points. The reader can obtain more detail in the cited literature.

For definiteness we consider a plane wave train normally incident from vacuum on a semi-infinite uniform medium of index of refraction $n(\omega)$ filling the region $x > 0$. From the Fresnel equations (7.42) and Problem 7.12 the amplitude of the electric field of the wave for $x > 0$ is given by

$$u(x, t) = \int_{-\infty}^{\infty} \left[\frac{2}{1 + n(\omega)} \right] A(\omega) e^{ik(\omega)x - i\omega t} d\omega \quad (7.124)$$

where

$$A(\omega) = \frac{1}{2\pi} \int_{-\infty}^{\infty} u_i(0, t) e^{i\omega t} dt \quad (7.125)$$

is the Fourier transform of the real incident electric field $u_i(x, t)$ evaluated just outside the medium, at $x = 0^-$. The wave number $k(\omega)$ is

$$k(\omega) = \frac{\omega}{c} n(\omega) \quad (7.126)$$

and is generally complex, with positive imaginary part corresponding to absorption of energy during propagation. Many media are sufficiently transparent that the wave number can be treated as real for most purposes, but there is always some damping present. [Parenthetically we observe that in (7.124) frequency, not wave number, is used as the independent variable. The change from the practice of the previous Sections 7.8 and 7.9 is dictated by the present emphasis on the *time* development of the wave at a fixed point in space.]

* A Sommerfeld, *Ann. Phys.* **44**, 177 (1914). L. Brillouin, *Ann. Phys.* **44**, 203 (1914).

(a) General Properties of $A(\omega)$

In order to discuss general aspects of the propagation we must know a little about $A(\omega)$ as a function of complex ω . Suppose that the incident wave has a well-defined front edge that reaches $x=0$ at $t=0$. Then it is true that

$$u_i(0, t) = 0, \quad \text{for } t < 0 \quad (7.127)$$

This condition, together with certain mathematical requirements that are physically reasonable, is both necessary and sufficient to assure that $A(\omega)$ is analytic in the upper half of the ω plane. The argument is entirely similar to the proof that the representation (7.112) implies analyticity of $\epsilon(\omega)$ in the upper half ω plane. In the lower half ω plane $A(\omega)$ will have singularities determined by the exact form of $u_i(0, t)$. The behavior for $|\omega| \rightarrow \infty$ is governed by the way in which $u_i(0, t)$ varies at very short times. For example, if

$$u_i(0, t) \rightarrow \frac{at^m}{m!}, \quad \text{for } t \rightarrow 0 \quad (7.128)$$

then

$$A(\omega) \rightarrow \frac{a}{2\pi} \left(\frac{i}{\omega} \right)^{m+1}, \quad \text{for } |\omega| \rightarrow \infty$$

(b) General Properties of $n(\omega)$ in the Complex ω Plane

The characteristics of the propagation obviously depend on the index of refraction $n(\omega)$ and detailed results require specification of a definite model. Some features follow, however, from general properties of $n(\omega)$ —its domain of analyticity and its behavior as $|\omega| \rightarrow \infty$. For simplicity we discuss the simple classical model for $n^2(\omega)$ described in Section 7.5, with only one resonant frequency. The dielectric constant $\epsilon(\omega) = n^2(\omega)$ is thus of the form,

$$n^2(\omega) = 1 + \frac{\omega_p^2}{\omega_0^2 - \omega^2 - i\omega\gamma} \quad (7.129)$$

where ω_0 is the resonant frequency, γ is the damping constant ($\gamma \geq 0$), and ω_p is the plasma frequency (7.60) of the medium. The singularity structure of $n(\omega)$ is determined by the location of the poles and zeros of $n^2(\omega)$ in the ω plane. The zeros of $n^2(\omega)$ are given by

$$\omega_a = \omega_1 - \frac{i\gamma}{2}, \quad \omega_b = -\omega_1 - \frac{i\gamma}{2}, \quad \text{with } \omega_1^2 = \omega_0^2 + \omega_p^2 - \frac{\gamma^2}{4}$$

The poles of $n^2(\omega)$ are located at

$$\omega_c = \omega_2 - \frac{i\gamma}{2}, \quad \omega_d = -\omega_2 - \frac{i\gamma}{2}, \quad \text{where } \omega_2^2 = \omega_0^2 - \frac{\gamma^2}{4}$$

The index of refraction can thus be written as

$$n(\omega) = \left[\frac{(\omega - \omega_a)(\omega - \omega_b)}{(\omega - \omega_c)(\omega - \omega_d)} \right]^{1/2} \quad (7.130)$$

Fig. 7.15 Branch cuts defining the singularities of the simple one-resonance model (7.129) for the index of refraction $n(\omega)$. For transparent media the branch cuts lie much closer to (but still below) the real axis than shown here. More realistic models for $n(\omega)$ have more complicated cut structures, all in the lower half ω plane. The crosses mark the possible locations of singularities of $A(\omega)$.

The branches of the square roots are defined so that $n(\omega) \rightarrow +1$ for $|\omega| \rightarrow \infty$; the branch cuts are shown in Fig. 7.15. The index of refraction and also the wave number $k(\omega)$ are seen to be analytic in the upper half ω plane.*

Inspection of (7.129) shows that for large frequencies the index of refraction goes as

$$n(\omega) \rightarrow 1 - \frac{\omega_p^2}{2\omega^2}, \quad \text{for } |\omega| \rightarrow \infty \quad (7.131)$$

This result holds more generally than the model would indicate, as has been discussed in connection with (7.59).

(c) Upper Limit for the Speed of Propagation of Light in Matter

Proof that no signal can propagate faster than the speed of light in vacuum, whatever the detailed properties of the medium, is now straightforward. We formally evaluate the amplitude (7.124) by contour integration. Since $n(\omega) \rightarrow 1$ for $|\omega| \rightarrow \infty$, the argument of the exponential in (7.124) becomes $i\omega(x-ct)/c$ for large ω , and the closing of the contour can be done in the upper half plane for $x > ct$ and the lower half plane for $x < ct$. With $n(\omega)$ and $A(\omega)$ analytic in the upper half ω plane the whole integrand in (7.124) is analytic there, and Cauchy's

* The branch cuts are chosen so that $\text{Re } n(\omega) > 0$ on the real axis. Note that $n(\omega)$ as well as $\epsilon(\omega)$ satisfies the Kramers-Kronig relations (7.120).

theorem shows that the integral vanishes. We have thus proved that

$$u(x, t) = 0, \quad \text{for } (x - ct) > 0 \quad (7.132)$$

provided $A(\omega)$ and $n(\omega)$ are analytic for $\text{Im } \omega > 0$ and $n(\omega) \rightarrow 1$ for $|\omega| \rightarrow \infty$. The specific model for $n(\omega)$ does not enter. Equation (7.132), together with (7.127), establishes that no signal propagates with a velocity greater than c , whatever the medium.

(d) Method of Stationary Phase

In order to go beyond the proof of causality, it is necessary to have some way of estimating the amplitude (7.124) at various times $t > x/c$. Sommerfeld and Brillouin used the method of *steepest descent** to evaluate (7.124) in various regimes. We will use the less rigorous and less accurate method of *stationary phase* to gain a qualitative understanding. In the book cited earlier, Brillouin compares the two approaches.

The method of stationary phase addresses itself to the problem of evaluating approximately integrals of the general type,

$$I = \int F(\omega) e^{i\phi(\omega)} d\omega \quad (7.133)$$

where $F(\omega)$ is a function that varies relatively slowly with ω and $\phi(\omega)$ is a phase that is generally large and rapidly varying. Both $F(\omega)$ and $\phi(\omega)$ may depend on parameters that are held constant during the integration. The rapid oscillations of $e^{i\phi}$ over most of the range of integration mean that the integrand averages to almost zero. Exceptions to this cancellation occur only when $\phi(\omega)$ is “stationary,” that is, when $\phi(\omega)$ has an extremum. The integral can therefore be estimated by finding the places where $\phi(\omega)$ has a vanishing derivative, evaluating approximately the integral in the neighborhood of each of these points, and summing the contributions.

Let $\phi(\omega)$ have a vanishing first derivative at $\omega = \omega_s$. In the neighborhood of this point, $\phi(\omega)$ can be expanded in a Taylor series,

$$\phi(\omega) = \phi_s + \frac{1}{2}\phi_s''(\omega - \omega_s)^2 + \cdots \quad (7.134)$$

Here the subscript s is used to indicate ϕ or its second derivative evaluated at $\omega = \omega_s$. Since $F(\omega)$ is slowly varying, the contribution to the integral from this stationary phase point is approximately

$$I_s \approx F(\omega_s) e^{i\phi_s} \int e^{(i/2)\phi_s''(\omega - \omega_s)^2} d\omega$$

The remaining integral can be recognized as a Fresnel integral (see *Magnus and*

* See *Jeffreys and Jeffreys*, Section 17.04, or *Born and Wolf*, Appendix III, for a discussion of this method, originally developed by P. Debye.

Oberhettinger, p. 96). The result is

$$I_s \approx \left(\frac{2\pi i}{\phi_s''} \right)^{1/2} F(\omega_s) e^{i\phi(\omega_s)} \quad (7.135)$$

where ω_s is defined by $(\partial\phi/\partial\omega)=0$ at $\omega=\omega_s$. If there is more than one point of stationary phase on the range of integration, the integral is approximated by a sum of terms like (7.135).

The stationary phase approximation (7.135) agrees with the leading term of the method of steepest descent provided $\phi(\omega)$ is real. If ϕ is complex, however, the stationary phase method can yield erroneous results. In the present problem ϕ involves the index of refraction $n(\omega)$, which is generally complex. Nevertheless, we will use the method of stationary phase to gain a qualitative understanding of the development of the signal. The more careful considerations of Brillouin give an a posteriori justification to our somewhat cavalier approach.

(e) Qualitative Discussion

The amplitude (7.124) can be viewed as having the form (7.133) with a phase,

$$\phi(\omega) = k(\omega)x - \omega t \quad (7.136)$$

with $k(\omega)$ given by (7.126). The points of stationary phase defined by $\partial\phi/\partial\omega=0$ satisfy the condition,

$$\frac{c}{\omega} \frac{dk}{d\omega} = \frac{ct}{x}, \quad \text{for } ct > x \quad (7.137)$$

Figure 7.16 shows the left-hand side of (7.137) as a function of frequency for the simple one-resonance model (7.129) with $\gamma=0$. The left-hand side of (7.137) is c/v_g , where v_g is the group velocity at frequency ω . With $\gamma=0$ the group velocity is less than c for all ω , except for $\omega_0 < \omega < \sqrt{\omega_0^2 + \omega_p^2}$, where it is purely imaginary. For $\gamma \neq 0$ the behavior in this region is more involved, as is shown in Fig. 7.13, but we ignore this complication here. Also shown in Fig. 7.16 is $ck/\omega = c/v_p$.

The frequency region that contributes to the amplitude at time t is determined graphically by finding the intersection of a horizontal line with ordinate $(ct/x) > 1$ with the solid curve in Fig. 7.16. For times immediately after $t_0 = x/c$ the point of stationary phase is seen to be at $\omega \rightarrow \infty$. With the approximation (7.131) for the behavior of $n(\omega)$ for large ω we find the point of stationary phase given by

$$\omega_s \approx \omega_p \sqrt{\frac{t_0}{2(t-t_0)}} \quad (7.138)$$

and its negative, of course. The stationary phase approximation (7.135) gives

$$u(x, t) \approx \frac{a}{2\pi} \left(\frac{\pi}{\xi} \right)^{1/2} \left(\frac{t-t_0}{\xi} \right)^{(m/2)-(1/4)} e^{-2i\sqrt{\xi(t-t_0)} + i(\pi/2)(m+1/2)} + \text{c.c.} \quad (7.139)$$

Fig. 7.16 The functions $c dk/d\omega = c/v_g$ and $n(\omega) = ck/\omega = c/v_p$ versus frequency for a simple one-resonance model (7.129) without damping for the index of refraction. The behavior far from resonance is physically reasonable, but not in the interval, $\omega_0 < \omega < \sqrt{\omega_0^2 + \omega_p^2}$ (this is the interval between ω_2 and ω_1 in Fig. 7.15). Points of stationary phase are given by the intersection of the horizontal line (ct/x) with the solid curve $c dk/d\omega$. For each point of stationary phase $\omega = \omega_s$, there is also one at $\omega = -\omega_s$, since the plotted functions are even in ω .

where

$$\xi = \frac{\omega_p^2 x}{2c} = \frac{\omega_p^2 t_0}{2} \quad (7.140)$$

In writing (7.139) we have made use of the specific behavior (7.128) for $A(\omega)$ at large ω . We reserve detailed comment on (7.139) until the next section where a more accurate result is derived. It suffices to note that the initial amplitude is very small, and oscillates with a (usually very high) frequency that depends only on the gross properties of the medium (ω_p) and the distance traveled ($x = ct_0$). This part of the signal is called the *first* or *Sommerfeld precursor* and is the earliest arrival.

At later times, as the horizontal line ct/x in Fig. 7.16 rises, the point of stationary phase moves to lower frequencies, into the region where the detailed

behavior of $n(\omega)$ and the location of its poles and branch cuts needs to be considered for an accurate description of the amplitude. In general the amplitude remains very small, however. Only when the elapsed time reaches

$$t_1 = k'(0)x = \frac{n(0)x}{c} \quad (7.141)$$

is there a qualitative change. This time marks the arrival of the *second* or *Brillouin precursor*. The reason for the qualitative change can be seen from Fig. 7.16. At $t = t_1$ the lower region of the $dk/d\omega$ curve is intersected for the first time and $\omega = 0$ becomes a point of stationary phase. This by itself would cause a qualitative change, making the amplitude oscillate with a considerably longer period than at earlier times. The most important aspect, however, is the *vanishing of the second derivative* of $k(\omega)$ at $\omega = 0$.^{*} This means that $\phi''_s = 0$. The stationary phase result (7.135) gives an infinite answer in such circumstances. The amplitude is not infinite, of course, but can be supposed to be much larger than before and of relatively long period at $t \approx t_1$. In order to obtain even an approximate result for the second precursor, it is necessary to go beyond the quadratic expansion (7.134). We examine this briefly below.

After the arrival of the second precursor there are, in our simple model, two points of stationary phase so that the amplitude becomes more complicated. Of more importance is the fact that $A(\omega)$ begins to dominate the behavior of the integral (7.124). It becomes inappropriate to use the method of stationary phase. The signal has arrived; the amplitude behaves in time as if it were the initial wave propagating with the appropriate phase velocity, as is shown below.

The qualitative features of the propagation of a signal are now clear. Some minute part of the wave propagates with the velocity of light in vacuum. This initial signal, called the first or Sommerfeld precursor, is very small and oscillates rapidly. At a later time t_1 (7.141) there is a sudden change when $\omega = 0$ becomes a point of stationary phase. The second or Brillouin precursor, of greater amplitude and longer period, arrives. At later times, depending on the details of $n(\omega)$ and the incident wave, the signal settles down to the expected steady-state behavior. It is evident that the exact build up of the signal is a complicated matter, that causality and relativity are obeyed regardless of the detailed dispersive properties of the medium, and that the arrival of the signal cannot be given an unambiguous definition. The general usage is to take the group velocity of the dominant frequency component as the signal velocity and velocity of energy transport. This suffices in most circumstances, but with sensitive enough detectors the signal velocity can evidently be pushed close to the velocity of light in vacuum, independent of the medium.

^{*} For more elaborate models of the index of refraction the vanishing of $d^2k/d\omega^2$ at a point of stationary phase may occur for $\omega \neq 0$. The discussion can be modified to handle such cases, but we will not bother to do so here. The reader is given the opportunity in Problem 7.17.

(f) First Precursor

A more accurate expression than (7.139) for the amplitude at early times can be obtained following Sommerfeld. We have seen that the amplitude at times soon after $t = t_0$ is determined by the behavior of the integrand in (7.124) at large frequencies. It is thus plausible to distort the path of integration in (7.124) into a semicircle of large radius R in the upper half ω plane. On this contour the leading behavior (7.128) and (7.131) for $A(\omega)$ and $n(\omega)$ can be used to write (7.124) in the approximate form,

$$u(x, t) \approx \frac{ai^m}{2\pi i} \oint \frac{d\omega}{\omega^{m+1}} e^{-i[(t-t_0)\omega + \xi/\omega]} \quad (7.142)$$

where the contour is taken in a positive (counterclockwise) sense around the whole circle of radius R . The extra piece added by extending the contour to the full circle is seen to be vanishingly small for large enough R , provided $(t-t_0) > 0$. A change of variable $w = -i(t-t_0)\omega$, transforms (7.142) into

$$u(x, t) \approx \frac{a}{2\pi i} (t-t_0)^m \oint \frac{dw}{w^{m+1}} e^{w - [\xi(t-t_0)/w]}$$

The integral is identifiable as proportional to an integral representation of a Bessel function if m is an integer. The specific form is

$$J_m(z) = \frac{1}{2\pi i} \left(\frac{z}{2}\right)^m \oint \frac{dw}{w^{m+1}} e^{w - (z^2/4w)} \quad (7.143)$$

where the contour is around the origin. The amplitude (7.142) is therefore

$$u(x, t) \approx a \left(\frac{t-t_0}{\xi}\right)^{m/2} J_m[2\sqrt{\xi(t-t_0)}] \quad (7.144)$$

Comparison of this expression with the approximation (7.139) of the method of stationary phase shows agreement provided we substitute the asymptotic form (3.91) for the Bessel function in (7.144). Equation (7.144) gives a description right down to $t = t_0$. The method of stationary phase breaks down very close to $t = t_0$ because the point of stationary phase moves to infinity and the steps from (7.133) are then not valid.

Before examining the behavior of the first precursor in detail, we remark on why (7.144) is only approximate. The reader's faith in Cauchy's theorem may be so great that he imagines that no approximation has been made. All we did was distort the contour and consider the integrand in a limit appropriate to that contour! But there lies the flaw. The exponential in (7.142) becomes very large in the upper half plane for large $(t-t_0)$ or large radius R . This means that nonleading terms in $A(\omega)$ and $n(\omega)$ make contributions that cannot be neglected. For example, the next term in the expansion of $u_i(0, t)$ in (7.128) might go as t^{m+1} . This would give a contribution to $A(\omega)$ varying as $(1/\omega)^{m+2}$ and lead to a term like (7.144) with m replaced by $m+1$. Evidently (7.144) describes the

amplitude only for times $(t-t_0)$ small compared to the dominant period present in the incident wave.

As remarked already, the first precursor is small and very rapidly oscillating, with a frequency that depends only on the gross properties of the medium and the distance traveled, and not at all on the frequency of the incident wave. The frequency of the oscillations of the precursor decreases with time because of the square root argument of the Bessel function. If the local frequency $\omega_l(t)$ is defined in terms of a half period between successive zeros of Bessel function, one finds $\omega_l(t) \approx \sqrt{\xi/(t-t_0)}$, with the initial value, $\omega_l(0) \approx \xi$. The amplitude grows very slowly in time, going as $(t-t_0)^{1/4}$ for $m=1$. The frequency parameter ξ , given by (7.140), depends on the plasma frequency of the medium. If all the electrons in each atom are assumed to contribute, the square of the plasma frequency is

$$\omega_p^2 = \frac{4\pi NZe^2}{m}$$

where Z is the atomic number and N is the number of atoms per unit volume. In terms of the density ρ in gm/cm^3 , atomic number Z and atomic weight A ,

$$\omega_p = 4.38 \sqrt{\frac{Z\rho}{A}} \times 10^{16} \text{ sec}^{-1}$$

or

$$\hbar\omega_p = 28.8 \sqrt{\frac{Z\rho}{A}} \text{ eV}$$

Some representative values are:

Air at N.T.P.,	$\omega_p \approx 1.1 \times 10^{15} \text{ sec}^{-1}$	$(\hbar\omega_p \approx 0.73 \text{ eV})$
Graphite,	$\omega_p \approx 3.9 \times 10^{16} \text{ sec}^{-1}$	$(\hbar\omega_p \approx 25.0 \text{ eV})$
Water,	$\omega_p \approx 3.3 \times 10^{16} \text{ sec}^{-1}$	$(\hbar\omega_p \approx 21.0 \text{ eV})$

With a typical value of $\omega_p \approx 10^{16} \text{ sec}^{-1}$ and a distance of 1 mm (corresponding to 2000 wavelengths of visible light), ξ is of the order of $\xi \approx 1.7 \times 10^{20} \text{ sec}^{-1}$. This corresponds to a wavelength of 10^{-9} cm , a tenth the linear dimension of atoms. Since our treatment is based on a continuum description of the medium, the rapid oscillations contained in (7.144) cannot be expected to be quantitatively reliable. As time goes on the frequency decreases in a square root fashion. In spite of this decrease in frequency, it is evident that, for our example at least, there are very many cycles of the precursor before any sizable fraction of a period of the incident wave has elapsed, only provided that its wavelength is in the optical range or longer.

(g) Second Precursor

The second or Brillouin precursor occurs when the elapsed time lies in the neighborhood of t_1 (7.141). As can be seen from Fig. 7.16, this is the time at

which, in the method of stationary phase, the integral receives its dominant contribution from around $\omega = 0$.* Since $\omega = 0$ is a point where ϕ'' , as well as ϕ' , vanishes, the simple result (7.135) is inadequate. To improve on this we expand $\phi(\omega)$, (7.136), around $\omega = 0$, keeping terms up to ω^3 :

$$\phi(\omega) \approx \omega(t_1 - t) + \frac{x}{6} \left(\frac{d^3 k}{d\omega^3} \right)_0 \omega^3 \quad (7.145)$$

For the simple model (7.129) of the index of refraction the third derivative of $k(\omega)$ is

$$\left(\frac{d^3 k}{d\omega^3} \right)_0 = \frac{3\omega_p^2}{cn(0)\omega_0^4}$$

The amplitude (7.124) is therefore given approximately by

$$u(x, t) \approx \frac{2A(0)}{1 + n(0)} \int_{-\infty}^{\infty} e^{i\omega(t_1 - t) + i(x/6)(d^3 k/d\omega^3)_0 \omega^3} d\omega$$

By a change of variable this can be written as

$$u(x, t) \approx \frac{4A(0)}{1 + n(0)} \left[\frac{3z}{x \left(\frac{d^3 k}{d\omega^3} \right)_0} \right]^{1/3} \int_0^{\infty} \cos \left[\frac{2}{3} z \left(\frac{v^3}{3} \pm v \right) \right] dv \quad (7.146)$$

where

$$z = \frac{2\sqrt{2} |t - t_1|^{3/2}}{3 \left(x \frac{d^3 k}{d\omega^3} \right)_0^{1/2}} \quad (7.147)$$

and the positive (negative) sign in the integrand is to be taken for $t < t_1$ ($t > t_1$). The integral in (7.146) is an Airy integral, first considered by G. B. Airy (1838) in his studies of the intensity of light in the neighborhood of a caustic (relevant

Fig. 7.17 The approximate behavior of the second or Brillouin precursor as a function of time. The amplitude is given by (7.146). The neglected contribution from the point of stationary phase at $\omega > \sqrt{\omega_0^2 + \omega_p^2}$ in Fig. 7.16 will superpose a high frequency ripple on the Airy integral behavior shown here.

* There is also a point of stationary phase above ω_0 , but the contribution from that region is much smaller than from $\omega \approx 0$ and will be neglected.

for the rainbow). It can be expressed in terms of Bessel functions of order $\frac{1}{3}$, as follows:

$$\int_0^\infty \cos \left[\frac{3}{2} z \left(\frac{v^3}{3} \pm v \right) \right] dv = \begin{cases} \frac{1}{\sqrt{3}} K_{1/3}(z) \\ \frac{\pi}{3} [J_{1/3}(z) + J_{-1/3}(z)] \end{cases} \quad (7.148)$$

From the properties of the Bessel functions in (7.148) the second precursor can be seen to have decaying exponential character for times earlier than $t = t_1$ [($t_1 - t$) increasing], and an oscillatory nature for ($t - t_1$) positive.* The amplitude in the neighborhood of $t = t_1$ is plotted in Fig. 7.17. The behavior is like that of a quantum-mechanical wave function at a classical turning point of the motion. The mathematics is, in fact, essentially the same even though the physics is different.

From the position of the first zero of the amplitude at $t > t_1$ the beginning frequency of the second precursor can be estimated as $\omega_{II}(0) \sim \pi(9xk''')^{-1/3}$. Using the simple one-resonance model with $\omega_0 \approx \omega_p \approx 10^{16} \text{ sec}^{-1}$ and $x = 1 \text{ mm}$ we find $\omega_{II}(0) \sim 10^{14} \text{ sec}^{-1}$. This value is extremely crude and also specific to the model and parameters chosen, but it does illustrate that the second precursor is of much lower frequency than the first. Since the dependence on distance of the frequency of the first and second precursor is as x and $x^{-1/3}$, respectively, the qualitative difference is magnified at large distances of travel in the medium.

(h) Steady-State Signal

After the arrival of the precursors the amplitude ultimately settles into a steady state related directly to the incident wave. To understand how this happens, consider the singularity structure shown in Fig. 7.15, and imagine the path of integration in (7.124) deformed, so that it is wrapped around the singularities of $A(\omega)$ (the crosses in Fig. 7.15) and the branch cuts of $n(\omega)$. The integrand in (7.124) contains a factor $e^{i\omega(t-t_0)}$. The contributions from the contour integrals around the branch cuts of $n(\omega)$ will thus contain a factor

$$e^{-(\gamma/2)(t-t_0)}$$

* The particular results, (7.146) and (7.148) depend on $A(0) \neq 0$. If $A(0) = 0$, the expressions are modified in detail, but are qualitatively the same. Specifically, if $A'(0) \neq 0$, $A(0)$ in (7.146) is replaced by $iA'(0)$, the factor $(3z/xk''')$ is raised to the $\frac{2}{3}$ power instead of the $\frac{1}{3}$ power, and the integral is replaced by

$$\int_0^\infty v \sin \left[\frac{3}{2} z \left(\frac{v^3}{3} \pm v \right) \right] dv = \begin{cases} \frac{1}{\sqrt{3}} K_{2/3}(z) \\ \frac{\pi}{3} [J_{-2/3}(z) - J_{2/3}(z)] \end{cases}$$

The behavior of this amplitude on either side of $t = t_1$ is similar to that shown in Fig. 7.17.

If the singularities of $A(\omega)$ are all closer to the real axis than the cuts of $n(\omega)$ (corresponding to one or more almost monochromatic waves incident), the singularities of $A(\omega)$ will ultimately dominate in the integral over those of $n(\omega)$. The amplitude will then be given accurately by an integration only over the contours wrapped around the singularities of $A(\omega)$.

For example, we consider an incident wave of the form

$$u_i(0, t) = \theta(t)e^{-\epsilon t} \sin(\beta - \nu t) \quad (7.149)$$

where $\theta(t)$ is the step function, β and ν are constants and ϵ is assumed infinitesimal. The Fourier transform (7.125) of this incident wave is

$$A(\omega) = \frac{1}{4\pi} \left(\frac{e^{i\beta}}{\omega - \nu + i\epsilon} - \frac{e^{-i\beta}}{\omega + \nu + i\epsilon} \right) \quad (7.150)$$

with simple poles at $\omega = \pm \nu - i\epsilon$. The contribution of these two poles to the integral (7.124) yields the amplitude,

$$u(x, t) = \frac{e^{i[k(\nu)x - \nu t + \beta - (\pi/2)]}}{1 + n(\nu)} + \text{c.c.} \quad (7.151)$$

This wave corresponds to an incident monochromatic wave of frequency ν being reduced in amplitude by the refraction at the surface of the medium and then propagating with its phase velocity $v_p = \nu/k(\nu)$. If absorption occurs the amplitude is diminished as it travels, according to the complex nature of $n(\nu)$.

(i) Experimental Observations on Precursors

The approximate results for the first precursor (7.144) and the second precursor (7.146) and also the arrival of the main signal have been verified by accurate numerical calculations for typical situations with a sinusoidal incident wave, and the simple one-resonance model for $\epsilon(\omega)$, with some small amount of damping.* At very early times the initial signal is given quite precisely by Sommerfeld's Bessel function approximation (7.144). The amplitude is very small and of high frequency. The Brillouin precursor, when it arrives at time t_1 (7.141), is of the form (7.146), but with a high frequency ripple superposed as expected. The incident signal, that is, something resembling the wave form at $x=0$, begins to be distinguishable at a time given by $t=x/v_g$, where v_g is the group velocity associated with the incident frequency, and is fully visible soon after.

More interesting is the experimental observation of the Sommerfeld and Brillouin precursors reported by Pleshko and Palócz.† A coaxial transmission line filled with a longitudinally magnetized ferrimagnetic material has, for its TEM mode, a dispersion characteristic that is almost the same as that shown in

* R. N. Cahn, private communication.

† P. Pleshko and I. Palócz, *Phys. Rev. Letters* **22**, 1201 (1969); IBM Research Division report RC 2488 (May 27, 1969).

Fig. 7.16, provided the “vacuum” speed c is scaled to $c' = c/\sqrt{\epsilon_r}$, ϵ_r being the dielectric constant in the absence of magnetization. The resonant and plasma frequencies are given in terms of the internal magnetic field H_i and saturation magnetization M_s as $\omega_0^2 = \gamma^2(H_i + 4\pi M_s)H_i$ and $\omega_p^2 = (4\pi M_s/H_i)\omega_0^2$, where γ is the gyromagnetic ratio. Variation of the applied magnetic field can thus be used to change the dispersion properties of the system. The material employed was aluminum-doped yttrium garnet. In one series of experiments a sinusoidal wave train with frequency $\nu/2\pi$ (in the notation of (7.149)) of 0.625 GHz and a rise time of approximately 1 nsec was incident. The results for three different applied magnetic fields are shown in Fig. 7.18. At 20 gauss the frequency ν lies between ω_0 and $\sqrt{\omega_0^2 + \omega_p^2}$ and therefore the main signal does not propagate. But the Sommerfeld and Brillouin precursors are visible in Fig. 7.18a. At 100 gauss,

Fig. 7.18 Experimental results on Sommerfeld and Brillouin precursors in dispersive media. A sinusoidal signal with a very short rise time is applied to a garnet-filled coaxial transmission line whose dispersion is similar to that of Fig. 7.16. The frequencies ω_0 and ω_p depend upon the applied magnetic field. (a) First and second precursors visible, but sinusoidal signal cut off. (b) Second precursor (compare Fig. 7.17), main signal still cut off. (c) Second precursor followed by propagating signal. (Figure courtesy of P. Pleshko and I. Palócz.)

the main signal still does not propagate; conditions are such that, while the first precursor is lost in the noise, the second is clearly visible and looks satisfyingly similar to the wave form of Fig. 7.17. The arrival times agree with the time t_1 within errors. At 200 gauss, where $\omega_0 \approx \omega_p$, the applied frequency ν lies below ω_0 . In Fig. 7.18c, the Brillouin precursor is seen, followed immediately by the propagating main signal.

While there is little reason to question the fundamental basis of the Sommerfeld-Brillouin treatment of signal propagation in a dispersive medium, it is nonetheless satisfying to see experimental evidence that the approximate methods of solution (stationary phase or steepest descent) preserve the essentials of the physics and mathematics. The application of the theory to the arrival of "whistlers," with their unusual dispersion characteristic (Fig. 7.10), is left to the problems.

REFERENCES AND SUGGESTED READING

The whole subject of optics as an electromagnetic phenomenon is treated authoritatively by

Born and Wolf.

Their first chapter covers plane waves, polarization, and reflection and refraction, among other topics. Stokes parameters are covered there and also by

Stone.

A very complete discussion of plane waves incident on boundaries of dielectrics and conductors is given by

Stratton, Chapter IX.

Another good treatment of electromagnetic waves in both isotropic and anisotropic media is that of

Landau and Lifshitz, *Electrodynamics of Continuous Media*, Chapters X and XI.

A more elementary, but clear and thorough, approach to plane waves and their properties appears in

Adler, Chu, and Fano, Chapters 7 and 8.

Propagation of waves in the ionosphere has, because of its practical importance, an extensive literature. The physical and mathematical aspects are covered in

Budden, *Radio Waves in the Ionosphere*,

Budden, *Lectures on Magnetoionic Theory*,

Wait.

The special topic of whistlers is discussed in detail in

R. A. Helliwell, *Whistlers and Related Ionospheric Phenomena*, Stanford University Press, (1965).

A survey of the basic physics involved in the interaction of light with matter can be found in the semipopular article by

V. F. Weisskopf, *Scientific American* **219**, 3, 60 (September 1968).

The propagation of waves in dispersive media is discussed in detail in the book by Brillouin.

The distortion and attenuation of pulses in dissipative materials are covered by Stratton, pp. 301-309.

Kramers-Kronig dispersion relations and their generalizations find application in many areas of physics. Examples in high-energy physics can be found in

Some uses in solid-state physics are discussed in the article by

F. Stern, in *Solid State Physics*, Vol. 15, eds. F. Seitz and D. Turnbull, Academic, New York (1963), pp. 299-408.

PROBLEMS

7.1 For each set of Stokes parameters given below deduce the amplitude of the electric field, up to an overall phase, in both linear polarization and circular polarization bases and make an accurate drawing similar to Fig. 7.4 showing the lengths of the axes of one of the ellipses and its orientation.

(a) $s_0 = 3$, $s_1 = -1$, $s_2 = 2$, $s_3 = -2$

(b) $s_0 = 25$, $s_1 = 0$, $s_2 = 24$, $s_3 = 7$

7.2 A plane wave is incident on a layered interface as shown in the figure below. The indices of refraction of the three nonpermeable media are n_1 , n_2 , n_3 . The thickness of the intermediate layer is d . The other media are each semi-infinite.

(a) Calculate the transmission and reflection coefficients (ratios of transmitted and reflected Poynting's flux to the incident flux), and sketch their behavior as a function of frequency for $n_1 = 1$, $n_2 = 2$, $n_3 = 3$; $n_1 = 3$, $n_2 = 2$, $n_3 = 1$; and $n_1 = 2$, $n_2 = 4$, $n_3 = 1$.

Problem 7.2

(b) The medium n_1 is part of an optical system (e.g., a lens); medium n_3 is air ($n_3 = 1$). It is desired to put an optical coating (medium n_2) on the surface so that there is no reflected wave for a frequency ω_0 . What thickness d and index of refraction n_2 are necessary?

7.3 Two plane semi-infinite slabs of the same uniform, isotropic, nonpermeable, lossless dielectric with index of refraction n are parallel and separated by an air gap ($n = 1$) of width d . A plane electromagnetic wave of frequency ω is incident on the gap from one of the slabs with angle of incidence i . For linear polarization both parallel to and perpendicular to the plane of incidence,

- (a) calculate the ratio of power transmitted into the second slab to the incident power and the ratio of reflected to incident power;
 (b) for i greater than the critical angle for total internal reflection, sketch the ratio of transmitted power to incident power as a function of d measured in units of wavelength in the gap.

7.4 A plane polarized electromagnetic wave of frequency ω in free space is incident normally on the flat surface of a nonpermeable medium of conductivity σ and dielectric constant ϵ .

- (a) Calculate the amplitude and phase of the reflected wave relative to the incident wave for arbitrary σ and ϵ .
 (b) Discuss the limiting cases of a very poor and a very good conductor, and show that for a good conductor the reflection coefficient (ratio of reflected to incident intensity) is approximately

$$R \approx 1 - 2 \frac{\omega}{c} \delta$$

where δ is the skin depth.

7.5 A plane polarized electromagnetic wave $\mathbf{E} = \mathbf{E}_i e^{i\mathbf{k} \cdot \mathbf{x} - i\omega t}$ is incident normally on a flat uniform sheet of an *excellent* conductor ($\sigma \gg \omega$) having a thickness D . Assuming that in space and in the conducting sheet $\mu = \epsilon = 1$, discuss the reflection and transmission of the incident wave.

- (a) Show that the amplitudes of the reflected and transmitted waves, correct to the first order in $(\omega/\sigma)^{1/2}$, are:

$$\frac{E_r}{E_i} = \frac{-(1 - e^{-2\lambda})}{(1 - e^{-2\lambda}) + \gamma(1 + e^{-2\lambda})}$$

$$\frac{E_t}{E_i} = \frac{2\gamma e^{-\lambda}}{(1 - e^{-2\lambda}) + \gamma(1 + e^{-2\lambda})}$$

where

$$\gamma = \sqrt{\frac{\omega}{2\pi\sigma}} (1 - i) = \frac{\omega\delta}{c} (1 - i)$$

$$\lambda = (1 - i)D/\delta$$

and $\delta = c/\sqrt{2\pi\omega\sigma}$ is the penetration depth.

- (b) Verify that for zero thickness and infinite thickness you obtain the proper limiting results.
 (c) Show that, except for sheets of very small thickness, the transmission coefficient is

$$T = \frac{8(\text{Re } \gamma)^2 e^{-2D/\delta}}{1 - 2e^{-2D/\delta} \cos(2D/\delta) + e^{-4D/\delta}}$$

Sketch $\log T$ as a function of (D/δ) , assuming $\text{Re } \gamma = 10^{-2}$.

Define "very small thickness."

7.6 A plane wave of frequency ω is incident normally from vacuum on a semi-infinite slab of material with a *complex* index of refraction $n(\omega)$ [$n^2(\omega) = \epsilon(\omega)$].

- (a) Show that the ratio of reflected power to incident power is

$$R = \left| \frac{1 - n(\omega)}{1 + n(\omega)} \right|^2$$

while the ratio of power transmitted into the medium to the incident power is

$$T = \frac{4 \operatorname{Re} n(\omega)}{[1 + n(\omega)]^2}$$

(b) Evaluate $\operatorname{Re} [i\omega(\mathbf{E} \cdot \mathbf{D}^* - \mathbf{B} \cdot \mathbf{H}^*)/8\pi]$ as a function of (x, y, z) . Show that this rate of change of energy per unit volume accounts for the relative transmitted power T .

(c) For a conductor, with $n^2 = 1 + i(4\pi\sigma/\omega)$, σ real, write out the results of (a) and (b) in the limit $\omega \ll \sigma$. Express your answer in terms of δ as much as possible. Calculate $\frac{1}{2} \operatorname{Re} (\mathbf{J}^* \cdot \mathbf{E})$ and compare with the result of (b). Do both enter the complex form of Poynting's theorem?

7.7 The time dependence of electrical disturbances in good conductors is governed by the frequency-dependent conductivity (7.58). Consider longitudinal electric fields in a conductor, using Ohm's law, the continuity equation, and the differential form of Coulomb's law.

(a) Show that the time-Fourier-transformed charge density satisfies the equation

$$[4\pi\sigma(\omega) - i\omega]\rho(\mathbf{x}, \omega) = 0$$

(b) Using the representation $\sigma(\omega) = \sigma_0/(1 - i\omega\tau)$, where $\sigma_0 = \omega_p^2\tau/4\pi$ and τ is a damping time, show that in the approximation $\omega_p\tau \gg 1$ any initial disturbance will oscillate with the plasma frequency and decay in amplitude with a decay constant $\lambda = 1/2\tau$. Note that if you use $\sigma(\omega) \approx \sigma(0) = \sigma_0$ in part (a), you will find no oscillations and extremely rapid damping with the (wrong) decay constant $\lambda_w = 4\pi\sigma_0$.

[W. M. Saslow and G. Wilkinson, *Am. J. Phys.* **39**, 1244 (1971)].

7.8 A stylized model of the ionosphere is a medium described by the dielectric constant (7.59). Consider the earth with such a medium beginning suddenly at a height h and extending to infinity. For waves with polarization both perpendicular to the plane of incidence (from a horizontal antenna) and in the plane of incidence (from a vertical antenna),

(a) Show from Fresnel's equations for reflection and refraction that for $\omega > \omega_p$ there is a range of angles of incidence for which reflection is not total, but for larger angles there is total reflection back toward the earth.

(b) A radio amateur operating at a wavelength of 21 meters in the early evening finds that she can receive distant stations located more than 1000 km away, but none closer. Assuming that the signals are being reflected from the F layer of the ionosphere at an effective height of 300 km, calculate the electron density. Compare with the known maximum and minimum F layer densities of $\sim 2 \times 10^6 \text{ cm}^{-3}$ in the daytime and $\sim (2-4) \times 10^5 \text{ cm}^{-3}$ at night.

7.9 A simple model of propagation of radio waves in the earth's atmosphere or ionosphere consists of a flat earth at $z=0$ and a nonuniform medium with $\epsilon = \epsilon(z)$ for $z > 0$. Consider the Maxwell equations under the assumption that the fields are independent of y and can be written as functions of z times $e^{i(kx - \omega t)}$.

(a) Show that the wave equation governing the propagation for $z > 0$ is

$$\frac{d^2 F}{dz^2} + q^2(z)F = 0$$

where

$$q^2(z) = \frac{\omega^2}{c^2} \epsilon(z) - k^2$$

and $F = E_y$ for horizontal polarization, and

$$q^2(z) = \frac{\omega^2}{c^2} \epsilon(z) + \frac{1}{2\epsilon} \frac{d^2\epsilon}{dz^2} - \frac{3}{4\epsilon^2} \left(\frac{d\epsilon}{dz} \right)^2 - k^2$$

with $F = \sqrt{\epsilon} E_z$ for vertical polarization.

(b) Use the WKB approximation to treat the propagation of waves directed vertically into the ionosphere ($k = 0$), assuming that the dielectric constant is given by (7.59) with a plasma frequency $\omega_p(z)$ governed by an electron density like that shown in Fig. 7.11. Verify that the qualitative arguments in Section 7.6 hold, with departures in detail only for $\omega \sim \omega_{p,\max}$.

(c) Using the WKB results of (b) and the concepts of the propagation of a pulse from Section 7.8, define an effective height of the ionosphere $h'(\omega)$ by calculating the time T for a pulse of dominant frequency ω to travel up and be reflected back ($h' \equiv cT/2$). [The WKB approximation is discussed in most books on quantum mechanics.]

7.10 Plane waves propagate in a homogeneous, nonpermeable, but *anisotropic* dielectric. The dielectric is characterized by a tensor ϵ_{ij} , but if coordinate axes are chosen as the principal axes the components of displacement along these axes are related to the electric-field components by $D_i = \epsilon_i E_i$ ($i = 1, 2, 3$), where ϵ_i are the eigenvalues of the matrix ϵ_{ij} .

(a) Show that plane waves with frequency ω and wave vector \mathbf{k} must satisfy

$$\mathbf{k} \times (\mathbf{k} \times \mathbf{E}) + \frac{\omega^2}{c^2} \mathbf{D} = 0$$

(b) Show that for a given wave vector $\mathbf{k} = k\mathbf{n}$ there are two distinct modes of propagation with different phase velocities $v = \omega/k$ which satisfy the Fresnel equation,

$$\sum_{i=1}^3 \frac{n_i^2}{v^2 - v_i^2} = 0$$

where $v_i = c/\sqrt{\epsilon_i}$ is called a principal velocity, and n_i is the component of \mathbf{n} along the i th principal axis.

(c) Show that $\mathbf{D}_a \cdot \mathbf{D}_b = 0$, where \mathbf{D}_a , \mathbf{D}_b are the displacements associated with the two modes of propagation.

7.11 An approximately monochromatic plane wave packet in one dimension has the instantaneous form, $u(x, 0) = f(x)e^{ik_0x}$, with $f(x)$ the modulation envelope. For each of the forms $f(x)$ below, calculate the wave-number spectrum $|A(k)|^2$ of the packet, sketch $|u(x, 0)|^2$ and $|A(k)|^2$, evaluate explicitly the rms deviations from the means, Δx and Δk (defined in terms of the intensities $|u(x, 0)|^2$ and $|A(k)|^2$), and test inequality (7.82).

(a) $f(x) = Ne^{-\alpha|x|/2}$

(b) $f(x) = Ne^{-\alpha^2 x^2/4}$

(c) $f(x) = \begin{cases} N(1 - \alpha|x|) & \text{for } \alpha|x| < 1 \\ 0 & \text{for } \alpha|x| > 1 \end{cases}$

(d) $f(x) = \begin{cases} N & \text{for } |x| < a \\ 0 & \text{for } |x| > a \end{cases}$

7.12 A homogeneous, isotropic, nonpermeable dielectric is characterized by an index of refraction $n(\omega)$ which is in general complex in order to describe absorptive processes.

(a) Show that the general solution for plane waves in one dimension can be written

$$u(x, t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} d\omega e^{-i\omega t} [A(\omega) e^{i(\omega/c)n(\omega)x} + B(\omega) e^{-i(\omega/c)n(\omega)x}]$$

where $u(x, t)$ is a component of \mathbf{E} or \mathbf{B} .

(b) If $u(x, t)$ is real, show that $n(-\omega) = n^*(\omega)$.

(c) Show that, if $u(0, t)$ and $\partial u(0, t)/\partial x$ are the boundary values of u and its derivative at $x=0$, the coefficients $A(\omega)$ and $B(\omega)$ are

$$\begin{cases} A(\omega) \\ B(\omega) \end{cases} = \frac{1}{2\sqrt{2\pi}} \int_{-\infty}^{\infty} dt e^{i\omega t} \left[u(0, t) \mp \frac{ic}{\omega n(\omega)} \frac{\partial u}{\partial x}(0, t) \right]$$

7.13 Consider the nonlocal (in time) connection between \mathbf{D} and \mathbf{E} ,

$$\mathbf{D}(\mathbf{x}, t) = \mathbf{E}(\mathbf{x}, t) + \int d\tau G(\tau) \mathbf{E}(\mathbf{x}, t - \tau)$$

with the $G(\tau)$ appropriate for the single-resonance model,

$$\epsilon(\omega) = 1 + \omega_p^2 (\omega_0^2 - \omega^2 - i\gamma\omega)^{-1}$$

(a) Convert the nonlocal connection between \mathbf{D} and \mathbf{E} into an instantaneous relation involving derivatives of \mathbf{E} with respect to time by expanding the electric field in the integral in a Taylor series in τ . Evaluate the integrals over $G(\tau)$ explicitly up to at least $\partial^2 \mathbf{E} / \partial t^2$.

(b) Show that the series obtained in (a) can be obtained formally by converting the frequency-representation relation, $\mathbf{D}(\mathbf{x}, \omega) = \epsilon(\omega) \mathbf{E}(\mathbf{x}, \omega)$ into a space-time relation,

$$\mathbf{D}(\mathbf{x}, t) = \epsilon \left(i \frac{\partial}{\partial t} \right) \mathbf{E}(\mathbf{x}, t)$$

where the variable ω in $\epsilon(\omega)$ is replaced by $\omega \rightarrow i(\partial/\partial t)$.

7.14 Use the Kramers-Kronig relation (7.120) to calculate the real part of $\epsilon(\omega)$, given the imaginary part of $\epsilon(\omega)$ for positive ω as

$$(a) \quad \text{Im } \epsilon = \lambda [\theta(\omega - \omega_1) - \theta(\omega - \omega_2)], \quad \omega_2 > \omega_1 > 0$$

$$(b) \quad \text{Im } \epsilon = \frac{\lambda \gamma \omega}{(\omega_0^2 - \omega^2)^2 + \gamma^2 \omega^2}$$

In each case sketch the behavior of $\text{Im } \epsilon(\omega)$ and the result for $\text{Re } \epsilon(\omega)$ as functions of ω . Comment on the reasons for similarities or differences of your results as compared with the curves in Fig. 7.8. The step function is $\theta(\mathbf{x}) = 0, \mathbf{x} < 0$ and $\theta(\mathbf{x}) = 1, \mathbf{x} > 0$.

7.15 Discuss the extension of the Kramers-Kronig relations (7.120) for a medium with a static electrical conductivity σ . Show that the first equation in (7.120) is unchanged, but that the second is changed into

$$\text{Im } \epsilon(\omega) = \frac{4\pi\sigma}{\omega} - \frac{2\omega}{\pi} P \int_0^{\infty} \frac{[\text{Re } \epsilon(\omega') - 1]}{\omega'^2 - \omega^2} d\omega'$$

[Hint: Consider $\epsilon(\omega) - 4\pi\sigma i/\omega$ as analytic for $\text{Im } \omega \geq 0$.]

- 7.16 (a) Use the relation (7.113) and the analyticity of $\epsilon(\omega)$ for $\text{Im } \omega \geq 0$ to prove that on the positive imaginary axis $\epsilon(\omega)$ is real and monotonically decreasing away from the origin toward unity as $\omega \rightarrow i\infty$, provided $\text{Im } \epsilon \geq 0$ for real positive frequencies.
 (b) With the assumption that $\text{Im } \epsilon$ vanishes for finite real ω only at $\omega = 0$, show that $\epsilon(\omega)$ has no zeros in the upper half ω plane.
 (c) Write down a Kramers-Kronig relation for $1/\epsilon(\omega)$ and deduce a sum rule similar to (7.122), but as an integral over $\text{Im } [1/\epsilon(\omega)]$.
 (d) With the one-resonance model (7.107) for $\epsilon(\omega)$ determine $\text{Im } \epsilon(\omega)$ and $\text{Im } [1/\epsilon(\omega)]$ and verify explicitly that the sum rules (7.122) and (c) are satisfied.

- 7.17 Equation (7.67) is an expression for the square of the index of refraction for waves propagating along field lines through a plasma in a uniform external magnetic field. Using this as a model for propagation in the magnetosphere, consider the arrival of a whistler signal (actually the Brillouin precursor and subsequently of Section 7.11).
 (a) Make a reasonably careful sketch of $c dk/d\omega$, where $k = \omega n(\omega)/c$, for the positive helicity wave, assuming $\omega_p/\omega_B \geq 1$. Indicate the interval where $c dk/d\omega$ is imaginary, but do not try to sketch it there!
 (b) Show that on the interval, $0 < \omega < \omega_B$, the minimum of $c dk/d\omega$ occurs at $\omega/\omega_B \approx \frac{1}{4}$, provided $\omega_p/\omega_B \geq 1$. Find approximate expressions for $c dk/d\omega$ for ω near zero and for ω near ω_B .
 (c) By means of the method of stationary phase and the general structure of the solution to Problem 7.12(a), show that the arrival of a whistler is signaled by a rising and falling frequency as a function of time, the falling frequency component being the source of the name.
 (d) (Optional) Consider the form of the signal in the Brillouin precursor. Show that it consists of a modulated waveform whose envelope is the Airy integral shape found by Brillouin and whose high frequency is $\omega_0 \approx \omega_B/4$. This then evolves into a signal beating with the two frequencies of part (c).

- 7.18 A charged particle (charge Ze) moves at constant velocity \mathbf{v} through a medium described by a dielectric function $\epsilon(\mathbf{q}, \omega)$ or, equivalently, by a conductivity function $\sigma(\mathbf{q}, \omega) = (i\omega/4\pi)[1 - \epsilon(\mathbf{q}, \omega)]$. It is desired to calculate the energy loss per unit time by the moving particle in terms of the dielectric function $\epsilon(\mathbf{q}, \omega)$ in the approximation that the electric field is the negative gradient of the potential and current flow obeys Ohm's law, $\mathbf{J}(\mathbf{q}, \omega) = \sigma(\mathbf{q}, \omega)\mathbf{E}(\mathbf{q}, \omega)$.
 (a) Show that with suitable normalization, the Fourier transform of the particle's charge density is

$$\rho(\mathbf{q}, \omega) = \frac{Ze}{(2\pi)^3} \delta(\omega - \mathbf{q} \cdot \mathbf{v})$$

- (b) Show that the Fourier components of the electrostatic potential are

$$\phi(\mathbf{q}, \omega) = \frac{4\pi \rho(\mathbf{q}, \omega)}{q^2 \epsilon(\mathbf{q}, \omega)}$$

- (c) Starting from $dW/dt = \int \mathbf{J} \cdot \mathbf{E} d^3x$ show that the energy loss per unit time can be written as

$$-\frac{dW}{dt} = \frac{Z^2 e^2}{\pi^2} \int \frac{d^3q}{q^2} \int_0^\infty d\omega \omega \text{Im} \left[\frac{1}{\epsilon(\mathbf{q}, \omega)} \right] \delta(\omega - \mathbf{q} \cdot \mathbf{v})$$

[This shows that $\text{Im} [\epsilon(\mathbf{q}, \omega)]^{-1}$ is related to energy loss and provides, by studying characteristic energy losses in thin foils, information on $\epsilon(\mathbf{q}, \omega)$ for solids.]

7.19 The angular momentum of a distribution of electromagnetic fields in vacuum is given by

$$\mathbf{L} = \frac{1}{4\pi c} \int d^3x \mathbf{x} \times (\mathbf{E} \times \mathbf{B})$$

where the integration is over all space.

(a) For fields produced a finite time in the past (and so localized to a finite region of space) show that, provided the magnetic field is eliminated in favor of the vector potential \mathbf{A} , the angular momentum can be written in the form

$$\mathbf{L} = \frac{1}{4\pi c} \int d^3x \left[\mathbf{E} \times \mathbf{A} + \sum_{j=1}^3 E_j (\mathbf{x} \times \nabla) A_j \right]$$

The first term is sometimes identified with the “spin” of the photon and the second with its “orbital” angular momentum because of the presence of the angular momentum operator $\mathbf{L}_{op} = -i(\mathbf{x} \times \nabla)$.

(b) Consider an expansion of the vector potential in the radiation gauge in terms of plane waves:

$$\mathbf{A}(\mathbf{x}, t) = \sum_{\mathbf{k}} \int \frac{d^3k}{(2\pi)^3} [\boldsymbol{\epsilon}_{\mathbf{k}}(\mathbf{k}) a_{\mathbf{k}}(\mathbf{k}) e^{i\mathbf{k} \cdot \mathbf{x} - i\omega t} + \text{c.c.}]$$

The polarization vectors $\boldsymbol{\epsilon}_{\mathbf{k}}(\mathbf{k})$ are conveniently chosen as the positive and negative helicity vectors $\boldsymbol{\epsilon}_{\pm} = (1/\sqrt{2})(\boldsymbol{\epsilon}_1 \pm i\boldsymbol{\epsilon}_2)$ where $\boldsymbol{\epsilon}_1$ and $\boldsymbol{\epsilon}_2$ are real orthogonal vectors in the x - y plane whose positive normal is in the direction of \mathbf{k} .

Show that the time average of the first (spin) term of \mathbf{L} can be written as

$$\mathbf{L}_{\text{spin}} = \frac{1}{2\pi c} \int \frac{d^3k}{(2\pi)^3} \mathbf{k} [|a_+(\mathbf{k})|^2 - |a_-(\mathbf{k})|^2]$$

Can the term “spin” angular momentum be justified from this expression? Calculate the energy of the field in terms of the plane wave expansion of \mathbf{A} and compare.

7.20 A circularly polarized plane wave moving in the z direction has a finite extent in the x and y directions. Assuming that the amplitude modulation is slowly varying (the wave is many wavelengths broad), show that the electric and magnetic fields are given approximately by

$$\mathbf{E}(x, y, z, t) \approx \left[E_0(x, y)(\mathbf{e}_1 \pm i\mathbf{e}_2) + \frac{i}{k} \left(\frac{\partial E_0}{\partial x} \pm i \frac{\partial E_0}{\partial y} \right) \mathbf{e}_3 \right] e^{ikz - i\omega t}$$

$$\mathbf{B} \approx \mp i\sqrt{\mu\epsilon} \mathbf{E}$$

where \mathbf{e}_1 , \mathbf{e}_2 , \mathbf{e}_3 are unit vectors in the x , y , z directions.

7.21 For the circularly polarized wave of Problem 7.20 calculate the time-averaged component of angular momentum parallel to the direction of propagation. Show that the ratio of this component of angular momentum to the energy of the wave is

$$\frac{L_3}{U} = \pm \omega^{-1}$$

Interpret this result in terms of quanta of radiation (photons). Show that for a cylindrically symmetric, finite plane wave the transverse components of angular momentum vanish.

8

Wave Guides and Resonant Cavities

Electromagnetic fields in the presence of metallic boundaries form a practical aspect of the subject of considerable importance. At high frequencies where the wavelengths are of the order of meters or less the only practical way of generating and transmitting electromagnetic radiation involves metallic structures with dimensions comparable to the wavelengths involved. In this chapter we consider first the fields in the neighborhood of a conductor and discuss their penetration into the surface and the accompanying resistive losses. Then the problems of waves guided in hollow metal pipes and of resonant cavities are treated from a fairly general viewpoint, with specific illustrations included along the way. Attenuation in wave guides and Q values of cavities are discussed from two different points of view. The earth-ionosphere system as a novel resonant cavity is treated next, followed by a brief discussion of dielectric wave guides. The normal mode expansion for an arbitrary field in a wave guide is presented

* In this chapter certain formulas, denoted by an asterisk on the equation number, are written so that they can be read as formulas in MKSA units provided the first factor in square brackets is omitted. For example, (8.12) is

$$\frac{dP_{\text{loss}}}{da} = \left[\frac{1}{4\pi} \right] \frac{\mu_c \omega \delta}{4} |\mathbf{H}_{\parallel}|^2$$

The corresponding equation in MKSA form is

$$\frac{dP_{\text{loss}}}{da} = \frac{\mu_c \omega \delta}{4} |\mathbf{H}_{\parallel}|^2$$

where all symbols are to be interpreted as MKSA symbols, perhaps with entirely different magnitudes and dimensions from those of the corresponding Gaussian symbols.

If an asterisk appears and there is no square bracket, the formula can be interpreted equally in Gaussian or MKSA symbols.

General rules for conversion of any equation into its corresponding MKSA form are given in Table 3 of the Appendix.

and applied to the fields generated by a localized source. The chapter ends with further application of the normal mode expansion to the treatment of obstacles in wave guides by variational methods.

8.1 Fields at the Surface of and within a Conductor

As was mentioned at the end of Section 7.7, the problem of reflection and refraction of waves at an interface of two conducting media is somewhat complicated. The most important and useful features of the phenomenon can, however, be obtained with an approximate treatment valid if one medium is a good conductor. Furthermore, the method, within its range of validity, is applicable to situations more general than incident plane waves.

First consider a surface with unit normal \mathbf{n} directed outward from a *perfect* conductor on one side into a nonconducting medium on the other side. Then, just as in the static case, there is no electric field inside the conductors. The charges inside a perfect conductor are assumed to be so mobile that they move instantly in response to changes in the fields, no matter how rapid, and always produce the correct surface-charge density Σ (capital Σ is used to avoid confusion with the conductivity σ):

$$\mathbf{n} \cdot \mathbf{D} = [4\pi]\Sigma \quad (8.1)^*$$

in order to give zero electric field inside the perfect conductor. Similarly, for time-varying magnetic fields, the surface charges move in response to the tangential magnetic field to produce always the correct surface current \mathbf{K} :

$$\mathbf{n} \times \mathbf{H} = \left[\frac{4\pi}{c} \right] \mathbf{K} \quad (8.2)^*$$

in order to have zero magnetic field inside the perfect conductor. The other two boundary conditions are on normal \mathbf{B} and tangential \mathbf{E} :

$$\left. \begin{aligned} \mathbf{n} \cdot (\mathbf{B} - \mathbf{B}_c) &= 0 \\ \mathbf{n} \times (\mathbf{E} - \mathbf{E}_c) &= 0 \end{aligned} \right\} \quad (8.3)^*$$

where the subscript c refers to the conductor. From these boundary conditions we see that just outside the surface of a perfect conductor only *normal* \mathbf{E} and *tangential* \mathbf{H} fields can exist, and that the fields drop abruptly to zero inside the perfect conductor. This behavior is indicated schematically in Fig. 8.1.

For a good, but not perfect, conductor the fields in the neighborhood of its surface must behave approximately the same as for a perfect conductor. In Section 7.7 we have seen that inside a conductor the fields are attenuated exponentially in a characteristic length δ , called the *skin depth*. For good conductors and moderate frequencies, δ is a small fraction of a centimeter.

Fig. 8.1 Fields near the surface of a perfect conductor.

Consequently, boundary conditions (8.1) and (8.2) are approximately true for a good conductor, aside from a thin transitional layer at the surface.

If we wish to examine that thin transitional region, however, care must be taken. First of all, Ohm's law $\mathbf{J} = \sigma \mathbf{E}$ shows that with a finite conductivity there cannot actually be a surface layer of current, as implied in (8.2). Instead, the boundary condition on the magnetic field is

$$\mathbf{n} \times (\mathbf{H} - \mathbf{H}_c) = 0 \quad (8.4)^*$$

To explore the changes produced by a finite, rather than an infinite, conductivity we employ a successive approximation scheme. First we assume that just outside the conductor there exists only a normal electric field \mathbf{E}_\perp and a tangential magnetic field \mathbf{H}_\parallel , as for a perfect conductor. The values of these fields are assumed to have been obtained from the solution of an appropriate boundary-value problem. Then we use the boundary conditions and the Maxwell equations in the conductor to find the fields within the transition layer and small corrections to the fields outside. In solving the Maxwell equations within the conductor we make use of the fact that the spatial variation of the fields normal to the surface is much more rapid than the variations parallel to the surface. This means that we can safely neglect all derivatives with respect to coordinates parallel to the surface compared to the normal derivative.

If there exists a tangential \mathbf{H}_\parallel outside the surface, boundary condition (8.4) implies the same \mathbf{H}_\parallel inside the surface. With the neglect of the displacement current in the conductor, the Maxwell curl equations become

$$\left. \begin{aligned} \mathbf{E}_c &\approx \frac{c}{4\pi\sigma} \nabla \times \mathbf{H}_c \\ \mathbf{H}_c &= -\frac{ic}{\mu_c \omega} \nabla \times \mathbf{E}_c \end{aligned} \right\} \quad (8.5)$$

where a harmonic variation $e^{-i\omega t}$ has been assumed. If \mathbf{n} is the unit normal outward from the conductor and ξ is the normal coordinate inward into the

conductor, then the gradient operator can be written

$$\nabla \approx -\mathbf{n} \frac{\partial}{\partial \xi}$$

neglecting the other derivatives when operating on the fields within the conductor. With this approximation (8.5) become:

$$\left. \begin{aligned} \mathbf{E}_c &\approx -\frac{c}{4\pi\sigma} \mathbf{n} \times \frac{\partial \mathbf{H}_c}{\partial \xi} \\ \mathbf{H}_c &\approx \frac{ic}{\mu_c \omega} \mathbf{n} \times \frac{\partial \mathbf{E}_c}{\partial \xi} \end{aligned} \right\} \quad (8.6)$$

These can be combined to yield

$$\left. \begin{aligned} \frac{\partial^2}{\partial \xi^2} (\mathbf{n} \times \mathbf{H}_c) + \frac{2i}{\delta^2} (\mathbf{n} \times \mathbf{H}_c) &\approx 0 \\ \mathbf{n} \cdot \mathbf{H}_c &\approx 0 \end{aligned} \right\} \quad (8.7)$$

where δ is the skin depth defined previously:

$$\delta = \left[\frac{c}{\sqrt{4\pi}} \right] \left(\frac{2}{\mu_c \omega \sigma} \right)^{1/2} \quad (8.8)^*$$

The second equation in (8.7) shows that inside the conductor \mathbf{H} is parallel to the surface, consistent with our boundary conditions. The solution for \mathbf{H}_c is:

$$\mathbf{H}_c = \mathbf{H}_{\parallel} e^{-\xi/\delta} e^{i\xi/\delta} \quad (8.9)$$

where \mathbf{H}_{\parallel} is the tangential magnetic field outside the surface. From (8.6) the electric field in the conductor is approximately:

$$\mathbf{E}_c \approx \sqrt{\frac{\mu_c \omega}{8\pi\sigma}} (1-i)(\mathbf{n} \times \mathbf{H}_{\parallel}) e^{-\xi/\delta} e^{i\xi/\delta} \quad (8.10)$$

These solutions for \mathbf{H} and \mathbf{E} inside the conductor exhibit the properties discussed in Section 7.7: (a) rapid exponential decay, (b) phase difference, (c) magnetic field much larger than the electric field. Furthermore, they show that, for a good conductor, the fields in the conductor are parallel to the surface[†] and propagate normal to it, with magnitudes which depend only on the tangential magnetic field \mathbf{H}_{\parallel} which exists just outside the surface.

[†] From the continuity of the tangential component of \mathbf{H} and the equation connecting \mathbf{E} to $\nabla \times \mathbf{H}$ on either side of the surface, one can show that there exists in the conductor a small normal component of electric field, $\mathbf{E}_c \cdot \mathbf{n} \approx (i\omega\epsilon/4\pi\sigma)E_{\perp}$, but this is of the next order in small quantities compared with (8.10). Note that our discussion here presupposes a tangential component of \mathbf{H} . In situations in which the lowest order approximation is essentially electrostatic, the present treatment is inapplicable. Different approximations must be employed. See T. H. Boyer, *Phys. Rev.* **A9**, 68 (1974).

From the boundary condition on tangential \mathbf{E} (8.3) we find that *just outside* the surface there exists a small tangential electric field given by (8.10), evaluated at $\xi=0$:

$$\mathbf{E}_{\parallel} \approx \sqrt{\frac{\mu_c \omega}{8\pi\sigma}} (1-i)(\mathbf{n} \times \mathbf{H}_{\parallel}) \quad (8.11)$$

In this approximation there is also a small normal component of \mathbf{B} just outside the surface. This can be obtained from Faraday's law of induction and gives \mathbf{B}_{\perp} of the same order of magnitude as \mathbf{E}_{\parallel} . The amplitudes of the fields both inside and outside the conductor are indicated schematically in Fig. 8.2.

The existence of a small tangential component of \mathbf{E} outside the surface, in addition to the normal \mathbf{E} and tangential \mathbf{H} , means that there is a power flow into the conductor. The time-average power absorbed per unit area is

$$\frac{dP_{\text{loss}}}{da} = -\frac{c}{8\pi} \text{Re} [\mathbf{n} \cdot \mathbf{E} \times \mathbf{H}^*] = \left[\frac{1}{4\pi} \right] \frac{\mu_c \omega \delta}{4} |\mathbf{H}_{\parallel}|^2 \quad (8.12)^*$$

This result can be given a simple interpretation as ohmic losses in the body of the conductor. According to Ohm's law, there exists a current density \mathbf{J} near the

Fig. 8.2 Fields near the surface of a good, but not perfect, conductor. For $\xi > 0$, the dashed curves show the envelope of the damped oscillations of \mathbf{H}_c (8.9).

surface of the conductor:

$$\mathbf{J} = \sigma \mathbf{E}_c = \sqrt{\frac{\mu_c \omega \sigma}{8\pi}} (1-i)(\mathbf{n} \times \mathbf{H}_{\parallel}) e^{-\xi(1-i)/\delta} \quad (8.13)$$

The time-average rate of dissipation of energy per unit volume in ohmic losses is $\frac{1}{2} \mathbf{J} \cdot \mathbf{E}^* = (1/2\sigma) |\mathbf{J}|^2$, so that the total rate of energy dissipation in the conductor for the volume lying beneath an area element ΔA is

$$\frac{1}{2\sigma} \Delta A \int_0^\infty d\xi \mathbf{J} \cdot \mathbf{J}^* = \Delta A \frac{\mu_c \omega}{8\pi} |\mathbf{H}_{\parallel}|^2 \int_0^\infty e^{-2\xi/\delta} d\xi = \Delta A \frac{\mu_c \omega \delta}{16\pi} |\mathbf{H}_{\parallel}|^2$$

This is the same rate of energy dissipation as given by the Poynting vector result (8.12).

The current density \mathbf{J} is confined to such a small thickness just below the surface of the conductor that it is equivalent to an effective surface current \mathbf{K}_{eff} :

$$\mathbf{K}_{\text{eff}} = \int_0^\infty \mathbf{J} d\xi = \left[\frac{c}{4\pi} \right] \mathbf{n} \times \mathbf{H}_{\parallel} \quad (8.14)^*$$

Comparison with (8.2) shows that a good conductor behaves effectively like a perfect conductor, with the idealized surface current replaced by an equivalent surface current which is actually distributed throughout a very small, but finite, thickness at the surface. The power loss can be written in terms of the effective surface current:

$$\frac{dP_{\text{loss}}}{da} = \frac{1}{2\sigma\delta} |\mathbf{K}_{\text{eff}}|^2 \quad (8.15)^*$$

This shows that $1/\sigma\delta$ plays the role of a surface resistance of the conductor.† Equation (8.15), with \mathbf{K}_{eff} given by (8.14), or (8.12) will allow us to calculate approximately the resistive losses for practical cavities, transmission lines, and wave guides, provided we have solved for the fields in the idealized problem of infinite conductivity.

8.2 Cylindrical Cavities and Wave Guides

A practical situation of great importance is the propagation or excitation of electromagnetic waves in hollow metallic cylinders. If the cylinder has end surfaces, it is called a cavity; otherwise, a wave guide. In our discussion of this problem the boundary surfaces will be assumed to be perfect conductors.

† The coefficient of proportionality linking \mathbf{E}_{\parallel} and \mathbf{K}_{eff} is called the *surface impedance* Z_s . For a good conductor (8.11) yields $Z_s = (1-i)/\sigma\delta$, but the concept of surface impedance obviously has wider applicability.

Fig. 8.3 Hollow, cylindrical wave guide of arbitrary cross-sectional shape.

The losses occurring in practice can be accounted for adequately by the methods of Section 8.1. A cylindrical surface S of general cross-sectional contour is shown in Fig. 8.3. For simplicity, the cross-sectional size and shape are assumed constant along the cylinder axis. With a sinusoidal time dependence $e^{-i\omega t}$ for the fields inside the cylinder, the Maxwell equations take the form:

$$\left. \begin{aligned} \nabla \times \mathbf{E} &= i \frac{\omega}{c} \mathbf{B} & \nabla \cdot \mathbf{B} &= 0 \\ \nabla \times \mathbf{B} &= -i\mu\epsilon \frac{\omega}{c} \mathbf{E} & \nabla \cdot \mathbf{E} &= 0 \end{aligned} \right\} \quad (8.16)$$

where it is assumed that the cylinder is filled with a uniform nondissipative medium having dielectric constant ϵ and permeability μ . It follows that both \mathbf{E} and \mathbf{B} satisfy

$$\left(\nabla^2 + \mu\epsilon \frac{\omega^2}{c^2} \right) \begin{Bmatrix} \mathbf{E} \\ \mathbf{B} \end{Bmatrix} = 0 \quad (8.17)$$

Because of the cylindrical geometry it is useful to single out the spatial variation of the fields in the z direction and to assume

$$\begin{Bmatrix} \mathbf{E}(x, y, z, t) \\ \mathbf{B}(x, y, z, t) \end{Bmatrix} = \begin{Bmatrix} \mathbf{E}(x, y) \\ \mathbf{B}(x, y) \end{Bmatrix} e^{\pm ikz - i\omega t} \quad (8.18)$$

Appropriate linear combinations can be formed to give traveling or standing waves in the z direction. The wave number k is, at present, an unknown parameter which may be real or complex. With this assumed z dependence of the fields the wave equation reduces to the two-dimensional form:

$$\left[\nabla_t^2 + \left(\mu\epsilon \frac{\omega^2}{c^2} - k^2 \right) \right] \begin{Bmatrix} \mathbf{E} \\ \mathbf{B} \end{Bmatrix} = 0 \quad (8.19)$$

where ∇_t^2 is the transverse part of the Laplacian operator:

$$\nabla_t^2 = \nabla^2 - \frac{\partial^2}{\partial z^2} \quad (8.20)$$

It is useful to separate the fields into components parallel to and transverse to the z axis:

$$\mathbf{E} = \mathbf{E}_z + \mathbf{E}_t \quad (8.21)$$

where

$$\begin{aligned}\mathbf{E}_z &= \mathbf{e}_3 E_z \\ \mathbf{E}_t &= (\mathbf{e}_3 \times \mathbf{E}) \times \mathbf{e}_3\end{aligned}\quad (8.22)$$

and \mathbf{e}_3 is a unit vector in the z direction. Similar definitions hold for the magnetic field \mathbf{B} . The Maxwell equations (8.16) can be written out in terms of transverse and parallel components as

$$\frac{\partial \mathbf{E}_t}{\partial z} + i \frac{\omega}{c} \mathbf{e}_3 \times \mathbf{B}_t = \nabla_t E_z, \quad \mathbf{e}_3 \cdot (\nabla_t \times \mathbf{E}_t) = i \frac{\omega}{c} B_z \quad (8.23)$$

$$\frac{\partial \mathbf{B}_t}{\partial z} - i \mu \epsilon \frac{\omega}{c} \mathbf{e}_3 \times \mathbf{E}_t = \nabla_t B_z, \quad \mathbf{e}_3 \cdot (\nabla_t \times \mathbf{B}_t) = -i \mu \epsilon \frac{\omega}{c} E_z \quad (8.24)$$

$$\nabla_t \cdot \mathbf{E}_t = -\frac{\partial E_z}{\partial z}, \quad \nabla_t \cdot \mathbf{B}_t = -\frac{\partial B_z}{\partial z} \quad (8.25)$$

It is evident from the first equations in (8.23) and (8.24) that if E_z and B_z are known the transverse components of \mathbf{E} and \mathbf{B} are determined, assuming the z dependence is given by (8.18).

Before considering the kinds of fields that can exist inside a hollow cylinder, we take note of a degenerate or special type of solution, called the *transverse electromagnetic* (TEM) wave. This solution has only field components transverse to the direction of propagation. From the second equation in (8.23) and the first in (8.25) it is seen that $E_z = 0$ and $B_z = 0$ imply that $\mathbf{E}_t = \mathbf{E}_{\text{TEM}}$ satisfies

$$\nabla_t \times \mathbf{E}_{\text{TEM}} = 0, \quad \nabla_t \cdot \mathbf{E}_{\text{TEM}} = 0 \quad (8.26)$$

This means that \mathbf{E}_{TEM} is a solution of an *electrostatic* problem in two dimensions. There are three main consequences. The first is that the axial wave number is given by the infinite-medium value,

$$k = k_0 = \left[\frac{1}{c} \right] \omega \sqrt{\mu \epsilon} \quad (8.27)^*$$

as can be seen from (8.19). The second consequence is that the magnetic field, deduced from the first equation in (8.24), is

$$\mathbf{B}_{\text{TEM}} = \pm \sqrt{\mu \epsilon} \mathbf{e}_3 \times \mathbf{E}_{\text{TEM}} \quad (8.28)$$

for waves propagating as $e^{\pm i k z}$. The connection between \mathbf{B}_{TEM} and \mathbf{E}_{TEM} is just the same as for plane waves in an infinite medium. The final consequence is that the TEM mode cannot exist inside a single, hollow, cylindrical conductor of infinite conductivity. The surface is an equipotential; the electric field therefore vanishes inside. It is necessary to have two or more cylindrical surfaces in order to support the TEM mode. The familiar coaxial cable and the parallel-wire transmission line are structures for which this is the

dominant mode. (See Problems 8.1 and 8.2.) An important property of the TEM mode is the absence of a cut-off frequency. The wave number (8.27) is real for all ω . This is not true for the modes occurring in hollow cylinders (see below).

In hollow cylinders (and on transmission lines at high frequencies) there occur two types of field configurations. Their existence can be seen from considering the wave equations (8.19) satisfied by the longitudinal components, E_z and B_z , and the boundary conditions to be satisfied. For a perfectly conducting cylinder the boundary conditions are

$$\mathbf{n} \times \mathbf{E} = 0, \quad \mathbf{n} \cdot \mathbf{B} = 0$$

where \mathbf{n} is a unit normal at the surface S . It is evident that the boundary condition on E_z is

$$E_z|_S = 0 \quad (8.29)$$

From the component of the first equation in (8.24) parallel to \mathbf{n} it can be inferred that the corresponding boundary condition on B_z is

$$\left. \frac{\partial B_z}{\partial n} \right|_S = 0 \quad (8.30)$$

where $\partial/\partial n$ is the normal derivative at a point on the surface. The two-dimensional wave equations (8.19) for E_z and B_z , together with the boundary conditions (8.29) and (8.30), specify eigenvalue problems of the usual sort. For a given frequency ω , only certain values of wave number k can occur (typical wave-guide situation), or, for a given k , only certain ω values are allowed (typical resonant cavity situation). *Since the boundary conditions on E_z and B_z are different, the eigenvalues will in general be different.* The fields thus naturally divide themselves into two distinct categories:

TRANSVERSE MAGNETIC (TM) WAVES

$$B_z = 0 \text{ everywhere; boundary condition, } E_z|_S = 0$$

TRANSVERSE ELECTRIC (TE) WAVES

$$E_z = 0 \text{ everywhere; boundary condition, } \left. \frac{\partial B_z}{\partial n} \right|_S = 0$$

The designations "Electric (or E) Waves" and "Magnetic (or H) Waves" are sometimes used instead of TM and TE waves, respectively, corresponding to a specification of the axial component of the fields. The various TM and TE waves, plus the TEM wave if it can exist, constitute a complete set of fields to describe an arbitrary electromagnetic disturbance in a wave guide or cavity.

8.3 Wave Guides

For the propagation of waves inside a hollow wave guide of uniform cross-section, it is found from the curl equations (8.23) and (8.24) that the transverse magnetic and electric fields for both TM and TE waves are related by

$$\mathbf{H}_t = \frac{\pm 1}{Z} \mathbf{e}_3 \times \mathbf{E}_t \quad (8.31)$$

where Z is called the *wave impedance* and is given by

$$Z = \begin{cases} \frac{ck}{\epsilon\omega} = \frac{k}{k_0} \sqrt{\frac{\mu}{\epsilon}} & \text{(TM)} \\ \frac{\mu\omega}{ck} = \frac{k_0}{k} \sqrt{\frac{\mu}{\epsilon}} & \text{(TE)} \end{cases} \quad (8.32)^*$$

where k_0 is given by (8.27). The plus (minus) sign in (8.31) goes with z dependence, e^{ikz} (e^{-ikz}). The transverse fields are determined by the longitudinal fields, according to

$$\begin{aligned} \text{TM WAVES:} \quad \mathbf{E}_t &= \pm \frac{ik}{\gamma^2} \nabla_t \psi \\ \text{TE WAVES:} \quad \mathbf{H}_t &= \pm \frac{ik}{\gamma^2} \nabla_t \psi \end{aligned} \quad (8.33)$$

where $\psi e^{\pm ikz}$ is E_z (H_z) for TM (TE) waves† and γ^2 is defined below. The scalar function ψ satisfies the two-dimensional wave equation (8.19),

$$(\nabla_t^2 + \gamma^2)\psi = 0 \quad (8.34)$$

where

$$\gamma^2 = \mu\epsilon \frac{\omega^2}{c^2} - k^2 \quad (8.35)$$

subject to the boundary condition,

$$\psi|_s = 0, \quad \text{or} \quad \frac{\partial \psi}{\partial n} \Big|_s = 0 \quad (8.36)$$

for TM (TE) waves.

Equation (8.34) for ψ , together with boundary condition (8.36), specifies an eigenvalue problem. It is easy to see that the constant γ^2 must be nonnegative. Roughly speaking, it is because ψ must be oscillatory in order to satisfy boundary condition (8.36) on opposite sides of the cylinder. There will be a

† We have changed from \mathbf{E} and \mathbf{B} to \mathbf{E} and \mathbf{H} as our basic fields to eliminate factors of μ when using the wave impedances. (Like ordinary impedance, wave impedance involves voltage and current and so \mathbf{E} and \mathbf{H} .)

spectrum of eigenvalues γ_λ^2 and corresponding solutions ψ_λ , $\lambda = 1, 2, 3, \dots$, which form an orthogonal set. These different solutions are called the *modes of the guide*. For a given frequency ω , the wave number k is determined for each value of λ :

$$k_\lambda^2 = \mu\epsilon \frac{\omega^2}{c^2} - \gamma_\lambda^2 \quad (8.37)$$

If we define a *cutoff frequency* ω_λ ,

$$\omega_\lambda = [c] \frac{\gamma_\lambda}{\sqrt{\mu\epsilon}} \quad (8.38)^*$$

then the wave number can be written:

$$k_\lambda = \left[\frac{1}{c} \right] \sqrt{\mu\epsilon} \sqrt{\omega^2 - \omega_\lambda^2} \quad (8.39)^*$$

We note that, for $\omega > \omega_\lambda$, the wave number k_λ is real; waves of the λ mode can propagate in the guide. For frequencies less than the cutoff frequency, k_λ is imaginary; such modes cannot propagate and are called *cutoff modes* or *evanescent modes*. The behavior of the axial wave number as a function of frequency is shown qualitatively in Fig. 8.4. We see that at any given frequency only a finite number of modes can propagate. It is often convenient to choose the dimensions of the guide so that at the operating frequency only the lowest mode can occur. This is shown by the vertical arrow on the figure.

Since the wave number k_λ is always less than the free-space value $\sqrt{\mu\epsilon} \omega/c$, the wavelength in the guide is always greater than the free-space wavelength. In turn, the phase velocity v_p is larger than the infinite space value:

$$v_p = \frac{\omega}{k_\lambda} = \frac{c}{\sqrt{\mu\epsilon}} \frac{1}{\sqrt{1 - \left(\frac{\omega_\lambda}{\omega}\right)^2}} > \frac{c}{\sqrt{\mu\epsilon}} \quad (8.40)$$

The phase velocity becomes infinite exactly at cutoff.

Fig. 8.4 Wave number k_λ versus frequency ω for various modes λ . ω_λ is the cutoff frequency.

8.4 Modes in a Rectangular Wave Guide

As an important illustration of the general features described in Section 8.3 we consider the propagation of TE waves in a rectangular wave guide with inner dimensions a , b , as shown in Fig. 8.5. The wave equation for $\psi = H_z$ is

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \gamma^2\right)\psi = 0 \quad (8.41)$$

with boundary conditions $\partial\psi/\partial n = 0$ at $x=0, a$ and $y=0, b$. The solution for ψ is consequently

$$\psi_{mn}(x, y) = H_0 \cos\left(\frac{m\pi x}{a}\right) \cos\left(\frac{n\pi y}{b}\right) \quad (8.42)$$

where

$$\gamma_{mn}^2 = \pi^2 \left(\frac{m^2}{a^2} + \frac{n^2}{b^2} \right) \quad (8.43)$$

The single index λ specifying the modes previously is now replaced by the two positive integers m, n . In order that there be nontrivial solutions, m and n cannot both be zero. The cutoff frequency ω_{mn} is given by

$$\omega_{mn} = [c] \frac{\pi}{\sqrt{\mu\epsilon}} \left(\frac{m^2}{a^2} + \frac{n^2}{b^2} \right)^{1/2} \quad (8.44)^*$$

If $a > b$, the lowest cutoff frequency, that of the dominant TE mode, occurs for $m=1, n=0$:

$$\omega_{1,0} = \frac{\pi c}{\sqrt{\mu\epsilon} a} \quad (8.45)$$

This corresponds to one-half of a free-space wavelength across the guide. The

Fig. 8.5

explicit fields for this mode, denoted by $TE_{1,0}$, are:

$$\begin{aligned} H_z &= H_0 \cos\left(\frac{\pi x}{a}\right) e^{ikz - i\omega t} \\ H_x &= -\frac{ika}{\pi} H_0 \sin\left(\frac{\pi x}{a}\right) e^{ikz - i\omega t} \\ E_y &= i \frac{\omega a \mu}{\pi c} H_0 \sin\left(\frac{\pi x}{a}\right) e^{ikz - i\omega t} \end{aligned} \quad (8.46)$$

where $k = k_{1,0}$ is given by (8.39) with $\omega_k = \omega_{1,0}$. The presence of a factor i in H_x (and E_y) means that there is a spatial (or temporal) phase difference of 90° between H_x (and E_y) and H_z in the propagation direction. It happens that the $TE_{1,0}$ mode has the lowest cutoff frequency of both TE and TM modes,[†] and so is the one used in most practical situations. For a typical choice $a = 2b$ the ratio of cutoff frequencies ω_{mn} for the next few modes to ω_{10} are as follows:

		$n \rightarrow$			
		0	1	2	3
	0		2.00	4.00	6.00
	1	1.00	2.24	4.13	
m	2	2.00	2.84	4.48	
\downarrow	3	3.00	3.61	5.00	
	4	4.00	4.48	5.66	
	5	5.00	5.39		
	6	6.00			

There is a frequency range from cutoff to twice cutoff or to (a/b) times cutoff, whichever is smaller, where the $TE_{1,0}$ mode is the only propagating mode. Beyond that frequency other modes rapidly begin to enter. The field configurations of the $TE_{1,0}$ mode and other modes are shown in many books, for example, *American Institute of Physics Handbook*, ed. D. E. Gray, 3rd edition, McGraw-Hill, New York (1972), p. 5-54.

8.5 Energy Flow and Attenuation in Wave Guides

The general discussion of Section 8.3 for a cylindrical wave guide of arbitrary cross-sectional shape can be extended to include the flow of energy along the

[†] This is evident if we note that for the TM modes E_z is of the form

$$E_z = E_0 \sin\left(\frac{m\pi x}{a}\right) \sin\left(\frac{n\pi y}{b}\right)$$

while γ^2 is still given by (8.43). The lowest mode has $m = n = 1$. Its cutoff frequency is greater than that of the $TE_{1,0}$ mode by the factor $\left(1 + \frac{a^2}{b^2}\right)^{1/2}$.

guide and the attenuation of the waves due to losses in the walls having finite conductivity. The treatment will be restricted to one mode at a time; degenerate modes will be mentioned only briefly. The flow of energy is described by the complex Poynting vector:

$$\mathbf{S} = \left[\frac{c}{4\pi} \right]^{1/2} (\mathbf{E} \times \mathbf{H}^*) \quad (8.47)^*$$

whose real part gives the time-averaged flux of energy. For the two types of field we find, using (8.31) and (8.33):

$$\mathbf{S} = \frac{\omega k}{8\pi\gamma^4} \begin{cases} \epsilon \left[\mathbf{e}_3 |\nabla_t \psi|^2 + i \frac{\gamma^2}{k} \psi \nabla_t \psi^* \right] \\ \mu \left[\mathbf{e}_3 |\nabla_t \psi|^2 - i \frac{\gamma^2}{k} \psi^* \nabla_t \psi \right] \end{cases} \quad (8.48)$$

where the upper (lower) line is for TM (TE) modes. Since ψ is generally real,[†] we see that the transverse component of \mathbf{S} represents reactive energy flow and does not contribute to the time-average flux of energy. On the other hand, the axial component of \mathbf{S} gives the time-averaged flow of energy along the guide. To evaluate the total power flow P we integrate the axial component of \mathbf{S} over the cross-sectional area A :

$$P = \int_A \mathbf{S} \cdot \mathbf{e}_3 da = \frac{\omega k}{8\pi\gamma^4} \left\{ \begin{matrix} \epsilon \\ \mu \end{matrix} \right\} \int_A (\nabla_t \psi)^* \cdot (\nabla_t \psi) da \quad (8.49)$$

By means of Green's first identity (1.34) applied to two dimensions, (8.49) can be written:

$$P = \frac{\omega k}{8\pi\gamma^4} \left\{ \begin{matrix} \epsilon \\ \mu \end{matrix} \right\} \left[\oint_C \psi^* \frac{\partial \psi}{\partial n} dl - \int_A \psi^* \nabla_t^2 \psi da \right] \quad (8.50)$$

where the first integral is around the curve C which defines the boundary surface of the cylinder. This integral vanishes for both types of fields because of boundary conditions (8.36). By means of the wave equation (8.34) the second integral may be reduced to the normalization integral for ψ . Consequently the transmitted power is

$$P = \left[\frac{c}{4\pi} \right] \frac{1}{2\sqrt{\mu\epsilon}} \left(\frac{\omega}{\omega_\lambda} \right)^2 \left(1 - \frac{\omega_\lambda^2}{\omega^2} \right)^{1/2} \left\{ \begin{matrix} \epsilon \\ \mu \end{matrix} \right\} \int_A \psi^* \psi da \quad (8.51)^*$$

where the upper (lower) line is for TM (TE) modes, and we have exhibited all the frequency dependence explicitly.

[†] It is possible to excite a guide in such a manner that a given mode or linear combination of modes has a complex ψ . Then a time-averaged transverse energy flow can occur. Since it is a circulatory flow, however, it really only represents stored energy and is not of great practical importance.

It is straightforward to calculate the field energy per unit length of the guide in the same way as the power flow. The result is

$$U = \left[\frac{1}{4\pi} \right] \frac{1}{2} \left(\frac{\omega}{\omega_\lambda} \right)^2 \left\{ \frac{\epsilon}{\mu} \right\} \int_A \psi^* \psi da \quad (8.52)^*$$

Comparison with the power flow P shows that P and U are proportional. The constant of proportionality has the dimensions of velocity (velocity of energy flow) and is just the group velocity:

$$\frac{P}{U} = \frac{k}{\omega} \frac{c^2}{\mu\epsilon} = \frac{c}{\sqrt{\mu\epsilon}} \sqrt{1 - \frac{\omega_\lambda^2}{\omega^2}} = v_g \quad (8.53)$$

as can be verified by a direct calculation of $v_g = d\omega/dk$ from (8.39), assuming that the dielectric filling the guide is nondispersive. We note that v_g is always less than the velocity of waves in an infinite medium and falls to zero at cutoff. The product of phase velocity (8.40) and group velocity is constant:

$$v_p v_g = \frac{c^2}{\mu\epsilon} \quad (8.54)$$

an immediate consequence of the fact that $\omega \Delta\omega \propto k \Delta k$.

Our considerations so far have applied to wave guides with perfectly conducting walls. The axial wave number k_λ was either real or purely imaginary. If the walls have a finite conductivity, there will be ohmic losses and the power flow along the guide will be attenuated. For walls with large conductivity the wave number will have small additional real and imaginary parts:

$$k_\lambda \approx k_\lambda^{(0)} + \alpha_\lambda + i\beta_\lambda \quad (8.55)^*$$

where $k_\lambda^{(0)}$ is the value for perfectly conducting walls. The change α_λ in the real part of the wave number is generally unimportant except near cutoff when $k_\lambda^{(0)} \rightarrow 0$. The attenuation constant β_λ can be found either by solving the boundary-value problem over again with boundary conditions appropriate for finite conductivity, or by calculating the ohmic losses by the methods of Section 8.1 and using conservation of energy. We will first use the latter technique. The power flow along the guide will be given by

$$P(z) = P_0 e^{-2\beta_\lambda z} \quad (8.56)^*$$

Thus the attenuation constant is given by

$$\beta_\lambda = -\frac{1}{2P} \frac{dP}{dz} \quad (8.57)^*$$

where $-dP/dz$ is the power dissipated in ohmic losses per unit length of the

guide. According to the results of Section 8.1, this power loss is

$$-\frac{dP}{dz} = \left[\frac{c^2}{16\pi^2} \right] \frac{1}{2\sigma\delta} \oint_C |\mathbf{n} \times \mathbf{H}|^2 dl \quad (8.58)^*$$

where the integral is around the boundary of the guide. With fields (8.31) and (8.33) it is easy to show that for a given mode:

$$-\frac{dP}{dz} = \frac{c^2}{32\pi^2\sigma\delta} \left(\frac{\omega}{\omega_\lambda} \right)^2 \oint_C \left\{ \frac{\frac{c^2}{\mu^2\omega_\lambda^2} \left| \frac{\partial\psi}{\partial n} \right|^2}{\frac{c^2}{\mu\epsilon\omega_\lambda^2} \left(1 - \frac{\omega_\lambda^2}{\omega^2} \right) |\mathbf{n} \times \nabla_t \psi|^2 + \frac{\omega_\lambda^2}{\omega^2} |\psi|^2} \right\} dl \quad (8.59)$$

where again the upper (lower) line applies to TM (TE) modes.

Since the transverse derivatives of ψ are determined entirely by the size and shape of the wave guide, the frequency dependence of the power loss is explicitly exhibited in (8.59). In fact, the integrals in (8.59) may be simply estimated from the fact that for each mode:

$$\left(\nabla_t^2 + \frac{\mu\epsilon\omega_\lambda^2}{c^2} \right) \psi = 0 \quad (8.60)$$

This means that, in some average sense, and barring exceptional circumstances, the transverse derivatives of ψ must be of the order of magnitude of $\sqrt{\mu\epsilon(\omega_\lambda/c)}\psi$:

$$\left\langle \left| \frac{\partial\psi}{\partial n} \right|^2 \right\rangle \sim \langle |\mathbf{n} \times \nabla_t \psi|^2 \rangle \sim \mu\epsilon \frac{\omega_\lambda^2}{c^2} \langle |\psi|^2 \rangle \quad (8.61)$$

Consequently the line integrals in (8.59) can be related to the normalization integral of $|\psi|^2$ over the area. For example,

$$\oint_C \frac{c^2}{\omega_\lambda^2} \left| \frac{\partial\psi}{\partial n} \right|^2 dl = \xi_\lambda \mu\epsilon \frac{C}{A} \int_A |\psi|^2 da \quad (8.62)$$

where C is the circumference and A is the area of cross section, while ξ_λ is a dimensionless number of the order of unity. Without further knowledge of the shape of the guide we can obtain the order of magnitude of the attenuation constant β_λ and exhibit completely its frequency dependence. Thus, using (8.59) with (8.62) and (8.51), plus the frequency dependence of the skin depth (8.8), we find

$$\beta_\lambda = \left[\frac{c}{4\pi} \right] \sqrt{\frac{\epsilon}{\mu}} \frac{1}{\sigma\delta_\lambda} \left(\frac{C}{2A} \right) \frac{\left(\frac{\omega}{\omega_\lambda} \right)^{1/2}}{\left(1 - \frac{\omega_\lambda^2}{\omega^2} \right)^{1/2}} \left[\xi_\lambda + \eta_\lambda \left(\frac{\omega_\lambda}{\omega} \right)^2 \right] \quad (8.63)^*$$

where σ is the conductivity (assumed independent of frequency), δ_λ is the skin depth at the cutoff frequency, and ξ_λ , η_λ are dimensionless numbers of the order of unity. For TM modes, $\eta_\lambda = 0$.

Fig. 8.6 Attenuation constant β_λ as a function of frequency for typical TE and TM modes. For TM modes the minimum attenuation occurs at $\omega/\omega_\lambda = \sqrt{3}$, regardless of cross-sectional shape.

For a given cross-sectional geometry it is a straightforward matter to calculate the dimensionless parameters ξ_λ and η_λ in (8.63). For the TE modes with $n=0$ in a rectangular guide, the values are $\xi_{m,0} = a/(a+b)$ and $\eta_{m,0} = 2b/(a+b)$. For reasonable relative dimensions, these parameters are of order unity, as expected.

The general behavior of β_λ as a function of frequency is shown in Fig. 8.6. Minimum attenuation occurs at a frequency well above cutoff. For TE modes the relative magnitudes of ξ_λ and η_λ depend on the shape of the guide and on λ . Consequently no general statement can be made about the exact frequency for minimum attenuation. But for TM modes the minimum always occurs at $\omega_{\min} = \sqrt{3}\omega_\lambda$. At high frequencies the attenuation increases as $\omega^{1/2}$. In the microwave region typical attenuation constants for copper guides are of the order $\beta_\lambda \sim 10^{-4} \omega_\lambda/c$, giving $1/e$ distances of 200–400 meters.

The approximations employed in obtaining (8.63) break down close to cutoff. Evidence for this is the physically impossible, infinite value of (8.63) at $\omega = \omega_\lambda$.

8.6 Perturbation of Boundary Conditions

The use of energy conservation to determine the attenuation constant β_λ is direct and has intuitive appeal, but gives physically meaningless results at cutoff and fails to yield a value for α_λ , the change in the real part of the wave number. Both of these defects can be remedied by use of the technique called *perturbation of boundary conditions*. This method is capable, at least in principle, of obtaining answers to any desired degree of accuracy, although we shall apply it only to the lowest order. It also permits the treatment of

attenuation for degenerate modes, mentioned briefly at the end of this section.

For definiteness we consider a single TM mode with no other mode (TE or TM) degenerate or nearly degenerate with it. The argument for an isolated TE mode is similar. To reduce the number of sub- and superscripts we denote the (unperturbed) solution for perfectly conducting walls by a subscript zero and the (perturbed) solution for walls of finite conductivity by no sub- or superscript. Thus the unperturbed problem has a longitudinal electric field $E_z = \psi_0$, where

$$(\nabla_t^2 + \gamma_0^2)\psi_0 = 0, \quad \psi_0|_s = 0 \quad (8.64)$$

and γ_0^2 is real. For finite, but large, conductivity, $E_z = \psi$ is not zero on the walls, but is given by (8.11). To lowest order, the right-hand side of (8.11) is approximated by the unperturbed fields. By use of the first equation in (8.23) and (8.33), the perturbed boundary condition on ψ can be expressed as

$$\psi|_s = f \frac{\partial \psi_0}{\partial n} \Big|_s \quad (8.65)$$

where the small complex parameter f is†

$$f = (1+i) \frac{\mu_c \delta}{2\mu} \left(\frac{\omega}{\omega_0} \right)^2 \quad (8.66)$$

Here μ_c and μ are the magnetic permeabilities of the conducting walls and the medium in the guide, respectively, δ is the skin depth (8.8), and ω_0 is the cutoff frequency of the unperturbed mode. The perturbed problem, equivalent to (8.64), is thus

$$(\nabla_t^2 + \gamma^2)\psi = 0, \quad \psi|_s = f \frac{\partial \psi_0}{\partial n} \Big|_s \quad (8.67)$$

If only the eigenvalue γ^2 is desired, Green's theorem (1.35) in two dimensions can be employed:

$$\int_A [\phi \nabla_t^2 \psi - \psi \nabla_t^2 \phi] da = \oint_C \left[\psi \frac{\partial \phi}{\partial n} - \phi \frac{\partial \psi}{\partial n} \right] dl$$

where the right-hand side has an *inwardly* directed normal [out of the conductor, in conformity with (8.11) and (8.65)]. With the identifications, $\psi = \psi$ and $\phi = \psi_0^*$, and use of the wave equations (8.64) and (8.67), and their boundary conditions, the statement of Green's theorem becomes

$$(\gamma_0^2 - \gamma^2) \int_A \psi_0^* \psi da = f \oint_C \left| \frac{\partial \psi_0}{\partial n} \right|^2 dl \quad (8.68)$$

† More generally, f can be expressed in terms of the surface impedance Z_s as $f = [c^2/4\pi](i\omega/\mu\omega_0^2)Z_s$, where the initial square bracket is omitted in MKSA units.

Since f is assumed to be a small parameter, it is normally consistent to approximate ψ in the integral on the left by its unperturbed value ψ_0 . This leads to the final result,

$$\gamma_0^2 - \gamma^2 = k^2 - k^{(0)2} \approx f \frac{\oint_C \left| \frac{\partial \psi_0}{\partial n} \right|^2 dl}{\int_A |\psi_0|^2 da} \quad (8.69)$$

From Eqs. (8.51) and (8.59) of the previous section one finds that the ratio of integrals on the right-hand side of (8.69) enters

$$2k^{(0)}\beta_{\text{TM}}^{(0)} = \frac{\mu_c \delta \left(\frac{\omega}{\omega_0} \right)^2}{2\mu} \frac{\oint_C \left| \frac{\partial \psi_0}{\partial n} \right|^2 dl}{\int_A |\psi_0|^2 da} \quad (8.70)$$

where $\beta^{(0)}$ is defined by (8.57) and (8.63). This means that (8.69) can be written as

$$k^2 \approx k^{(0)2} + 2(1+i)k^{(0)}\beta^{(0)} \quad (8.71)$$

a result that holds for both TM and TE modes, with the appropriate $\beta^{(0)}$ from the previous section. For $k^{(0)} \gg \beta^{(0)}$, (8.71) reduces to the former expression (8.55) with $\alpha = \beta$. At cutoff and below, however, where the previous results failed, (8.71) yields sensible results since the combination $k^{(0)}\beta^{(0)}$ is finite and well-behaved in the neighborhood of $k^{(0)} = 0$. The transition from a propagating mode to a cutoff mode is evidently not a sharp one if the walls are less than perfect conductors, but the attenuation is sufficiently large immediately above and below the cutoff frequency that little error is made in assuming a sharp cutoff.

The discussion of attenuation here and in the previous section is restricted to one mode at a time. For nondegenerate modes with not too great losses this approximation is adequate. If, however, it happens that a TM and a TE mode are degenerate (as occurs in the rectangular wave guide for $n \neq 0$, $m \neq 0$), then any perturbation, no matter how small, can cause sizable mixing of the two modes. The methods used so far fail in such circumstances. The breakdown of the present method occurs in the perturbed boundary condition (8.65), where there is now on the right-hand side a term involving the tangential derivative of the unperturbed H_z , as well as the normal derivative of E_z . And there is, of course, a corresponding perturbed boundary condition for H_z involving both unperturbed longitudinal fields. The problem is one of degenerate-state perturbation theory, most familiar in the context of quantum mechanics. The perturbed modes are orthogonal linear combinations of the unperturbed TM and TE modes, and the attenuation constants for the two

modes have the characteristic expression,

$$\beta = \frac{1}{2}(\beta_{TM} + \beta_{TE}) \pm \frac{1}{2}\sqrt{(\beta_{TM} - \beta_{TE})^2 + 4|K|^2} \quad (8.72)$$

where β_{TM} and β_{TE} are the values found above, and K is a coupling parameter.

The treatment of attenuation for degenerate modes using perturbation of boundary conditions has been given by a number of authors.[†] The discussion of Papadopoulos is presented in the book by Collin, Section 5.3.

8.7 Resonant Cavities

Although an electromagnetic cavity resonator can be of any shape whatsoever, an important class of cavities is produced by placing end faces on a length of cylindrical wave guide. We will assume that the end surfaces are plane and perpendicular to the axis of the cylinder. As usual, the walls of the cavity are taken to have infinite conductivity, while the cavity is filled with a lossless dielectric with constants μ , ϵ . Because of reflections at the end surfaces the z dependence of the fields will be that appropriate to standing waves:

$$A \sin kz + B \cos kz$$

If the plane boundary surfaces are at $z=0$ and $z=d$, the boundary conditions can be satisfied at each surface only if

$$k = p \frac{\pi}{d}, \quad p = 0, 1, 2, \dots \quad (8.73)$$

For TM fields the vanishing of E_z at $z=0$ and $z=d$ requires

$$E_z = \psi(x, y) \cos\left(\frac{p\pi z}{d}\right), \quad p = 0, 1, 2, \dots \quad (8.74)$$

Similarly for TE fields, the vanishing of H_z at $z=0$ and $z=d$ requires

$$H_z = \psi(x, y) \sin\left(\frac{p\pi z}{d}\right), \quad p = 1, 2, 3, \dots \quad (8.75)$$

[†] G. Goubau, *Electromagnetic Waveguides and Cavities*, Pergamon Press, London (1961), Section 25.

V. M. Papadopoulos, *Quart. J. Mech. and Appl. Math.* **7**, 325 (1954).

Then from (8.31) and (8.33) we find the transverse fields:

TM FIELDS

$$\begin{aligned} \mathbf{E}_t &= -\frac{p\pi}{d\gamma^2} \sin\left(\frac{p\pi z}{d}\right) \nabla_t \psi \\ \mathbf{H}_t &= \frac{i\epsilon\omega}{c\gamma^2} \cos\left(\frac{p\pi z}{d}\right) \mathbf{e}_3 \times \nabla_t \psi \end{aligned} \quad (8.76)$$

TE FIELDS

$$\begin{aligned} \mathbf{E}_t &= -\frac{i\omega\mu}{c\gamma^2} \sin\left(\frac{p\pi z}{d}\right) \mathbf{e}_3 \times \nabla_t \psi \\ \mathbf{H}_t &= \frac{p\pi}{d\gamma^2} \cos\left(\frac{p\pi z}{d}\right) \nabla_t \psi \end{aligned} \quad (8.77)$$

The boundary conditions at the ends of the cavity are now explicitly satisfied. There remains the eigenvalue problem (8.34)–(8.36), as before. But now the constant γ^2 is:

$$\gamma^2 = \mu\epsilon \frac{\omega^2}{c^2} - \left(\frac{p\pi}{d}\right)^2 \quad (8.78)$$

For each value of p the eigenvalue γ_λ^2 determines an eigenfrequency $\omega_{\lambda p}$:

$$\omega_{\lambda p}^2 = \frac{[c^2]}{\mu\epsilon} \left[\gamma_\lambda^2 + \left(\frac{p\pi}{d}\right)^2 \right] \quad (8.79)^*$$

and the corresponding fields of that resonant mode. The resonance frequencies form a discrete set which can be determined graphically on the figure of axial wave number k versus frequency in a wave guide (see p. 344) by demanding that $k = p\pi/d$. It is usually expedient to choose the various dimensions of the cavity so that the resonant frequency of operation lies well separated from other resonant frequencies. Then the cavity will be relatively stable in operation and insensitive to perturbing effects associated with frequency drifts, changes in loading, etc.

An important practical resonant cavity is the right circular cylinder, perhaps with a piston to allow tuning by varying the height. The cylinder is shown in Fig. 8.7, with inner radius R and length d . For a TM mode the transverse wave equation for $\psi = E_z$, subject to the boundary condition $E_z = 0$ at $\rho = R$, has the solution:

$$\psi(\rho, \phi) = E_0 J_m(\gamma_{mn}\rho) e^{\pm im\phi} \quad (8.80)$$

where

$$\gamma_{mn} = \frac{x_{mn}}{R}$$

Fig. 8.7

x_{mn} is the n th root of the equation, $J_m(x)=0$. These roots are given on page 105, below equation (3.92). The integers m and n take on the values $m=0, 1, 2, \dots$, and $n=1, 2, 3, \dots$. The resonance frequencies are given by

$$\omega_{mnp} = \frac{[c]}{\sqrt{\mu\epsilon}} \sqrt{\frac{x_{mn}^2}{R^2} + \frac{p^2\pi^2}{d^2}} \quad (8.81)^*$$

The lowest TM mode has $m=0$, $n=1$, $p=0$, and so is designated $\text{TM}_{0,1,0}$. Its resonance frequency is

$$\omega_{010} = \frac{2.405}{\sqrt{\mu\epsilon}} \frac{c}{R}$$

The explicit expressions for the fields are

$$\left. \begin{aligned} E_z &= E_0 J_0 \left(\frac{2.405\rho}{R} \right) e^{-i\omega t} \\ H_\phi &= -i\sqrt{\frac{\epsilon}{\mu}} E_0 J_1 \left(\frac{2.405\rho}{R} \right) e^{-i\omega t} \end{aligned} \right\} \quad (8.82)$$

The resonant frequency for this mode is independent of d . Consequently simple tuning is impossible.

For TE modes, the basic solution (8.80) still applies, but the boundary condition on H_z $\left(\frac{\partial \psi}{\partial \rho} \Big|_R = 0 \right)$ makes

$$\gamma_{mn} = \frac{x'_{mn}}{R}$$

where x'_{mn} is the n th root of $J'_m(x)=0$. These roots, for a few values of m and

n , are tabulated below (for $m \neq 1$, $x=0$ is a trivial root):

Roots of $J'_m(x)=0$

$$m=0: \quad x'_{0n}=3.832, 7.016, 10.173, \dots$$

$$m=1: \quad x'_{1n}=1.841, 5.331, 8.536, \dots$$

$$m=2: \quad x'_{2n}=3.054, 6.706, 9.970, \dots$$

$$m=3: \quad x'_{3n}=4.201, 8.015, 11.336, \dots$$

The resonance frequencies are given by

$$\omega_{mnp} = \frac{[c]}{\sqrt{\mu\epsilon}} \left(\frac{x'^2_{mn}}{R^2} + \frac{p^2 \pi^2}{d^2} \right)^{1/2} \quad (8.83)^*$$

where $m=0, 1, 2, \dots$, but $n, p=1, 2, 3, \dots$. The lowest TE mode has $m=n=p=1$, and is denoted $\text{TE}_{1,1,1}$. Its resonance frequency is

$$\omega_{111} = \frac{1.841}{\sqrt{\mu\epsilon}} \frac{c}{R} \left(1 + 2.912 \frac{R^2}{d^2} \right)^{1/2} \quad (8.84)$$

while the fields are derivable from

$$\psi = H_z = H_0 J_1 \left(\frac{1.841 \rho}{R} \right) \cos \phi \sin \left(\frac{\pi z}{d} \right) e^{-i\omega t} \quad (8.85)$$

by means of (8.77). For d large enough ($d > 2.03R$), the resonance frequency ω_{111} is smaller than that for the lowest TM mode. Then the $\text{TE}_{1,1,1}$ mode is the fundamental oscillation of the cavity. Because the frequency depends on the ratio d/R it is possible to provide easy tuning by making the separation of the end faces adjustable.

8.8 Power Losses in a Cavity; Q of a Cavity

In the preceding section it was found that resonant cavities had discrete frequencies of oscillation with a definite field configuration for each resonance frequency. This implies that, if one were attempting to excite a particular mode of oscillation in a cavity by some means, no fields of the right sort could be built up unless the exciting frequency were exactly equal to the chosen resonance frequency. In actual fact there will not be a delta function singularity, but rather a narrow band of frequencies around the eigenfrequency over which appreciable excitation can occur. An important source of this smearing out of the sharp frequency of oscillation is the dissipation of energy in the cavity walls and perhaps in the dielectric filling the cavity. A measure of the sharpness of response of the cavity to external excitation is the Q of the cavity, defined as 2π times the ratio of the time-averaged energy

stored in the cavity to the energy loss per cycle:

$$Q = \omega_0 \frac{\text{Stored energy}}{\text{Power loss}} \quad (8.86)^*$$

Here ω_0 is the resonance frequency, assuming no losses. By conservation of energy the power dissipated in ohmic losses is the negative of the time rate of change of stored energy U . Thus from (8.86) we can write an equation for the behavior of U as a function of time:

$$\left. \begin{aligned} \frac{dU}{dt} &= -\frac{\omega_0}{Q} U \\ \text{with solution} \quad U(t) &= U_0 e^{-\omega_0 t/Q} \end{aligned} \right\} \quad (8.87)$$

If an initial amount of energy U_0 is stored in the cavity, it decays away exponentially with a decay constant inversely proportional to Q . The time dependence in (8.87) implies that the oscillations of the fields in the cavity are damped as follows:

$$E(t) = E_0 e^{-\omega_0 t/2Q} e^{-i(\omega_0 + \Delta\omega)t} \quad (8.88)$$

where we have allowed for a shift $\Delta\omega$ of the resonant frequency as well as the damping. A damped oscillation such as this has not a pure frequency, but a superposition of frequencies around $\omega = \omega_0 + \Delta\omega$. Thus,

$$\left. \begin{aligned} E(t) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} E(\omega) e^{-i\omega t} d\omega \\ \text{where} \quad E(\omega) &= \frac{1}{\sqrt{2\pi}} \int_0^{\infty} E_0 e^{-\omega_0 t/2Q} e^{i(\omega - \omega_0 - \Delta\omega)t} dt \end{aligned} \right\} \quad (8.89)$$

The integral in (8.89) is elementary and leads to a frequency distribution for the energy in the cavity having a resonant line shape:

$$|E(\omega)|^2 \propto \frac{1}{(\omega - \omega_0 - \Delta\omega)^2 + (\omega_0/2Q)^2} \quad (8.90)$$

The resonance shape (8.90), shown in Fig. 8.8, has a full width Γ at half-maximum (confusingly called the half-width) equal to ω_0/Q . For a constant input voltage, the energy of oscillation in the cavity as a function of frequency will follow the resonance curve in the neighborhood of a particular resonant frequency. Thus, the frequency separation $\delta\omega$ between half-power points determines the width Γ and the Q of cavity is

$$Q = \frac{\omega_0}{\delta\omega} = \frac{\omega_0}{\Gamma} \quad (8.91)$$

Fig. 8.8 Resonance line shape. The full width Γ at half-maximum (of the power) is equal to the unperturbed frequency ω_0 divided by the Q of the cavity.

Q values of several hundreds or thousands are common for microwave cavities.

To determine the Q of a cavity we can calculate the time-averaged energy stored in it and then determine the power loss in the walls. The computations are very similar to those done in Section 8.5 for attenuation in wave guides. We will consider here only the cylindrical cavities of Section 8.7, assuming no degeneracies. The energy stored in the cavity for the mode λ , p is, according to (8.74)–(8.77):

$$U = \left[\frac{1}{4\pi} \right] \frac{d}{4} \left\{ \frac{\epsilon}{\mu} \right\} \left[1 + \left(\frac{p\pi}{\gamma_\lambda d} \right)^2 \right] \int_A |\psi|^2 da \quad (8.92)^*$$

where the upper (lower) line applies to TM (TE) modes. For the TM modes with $p=0$ the result must be multiplied by 2.

The power loss can be calculated by a modification of (8.58):

$$P_{\text{loss}} = \left[\frac{c^2}{16\pi^2} \right] \frac{1}{2\sigma\delta} \left[\oint_C dl \int_0^d dz |\mathbf{n} \times \mathbf{H}|_{\text{sides}}^2 + 2 \int_A da |\mathbf{n} \times \mathbf{H}|_{\text{ends}}^2 \right] \quad (8.93)^*$$

For TM modes with $p \neq 0$ it is easy to show that

$$P_{\text{loss}} = \left[\frac{c^2}{16\pi^2} \right] \frac{\epsilon}{\sigma\delta\mu} \left[1 + \left(\frac{p\pi}{\gamma_\lambda d} \right)^2 \right] \left(1 + \xi_\lambda \frac{Cd}{4A} \right) \int_A |\psi|^2 da \quad (8.94)^*$$

where the dimensionless number ξ_λ is the same one that appears in (8.62), C is the circumference of the cavity, and A is its cross-sectional area. For $p=0$, ξ_λ must be replaced by $2\xi_\lambda$. Combining (8.92) and (8.94) according to (8.86), and using definition (8.8) for the skin depth δ , we find the Q of the cavity:

$$Q = \frac{\mu}{\mu_c} \frac{d}{\delta} \frac{1}{2 \left(1 + \xi_\lambda \frac{Cd}{4A} \right)} \quad (8.95)^*$$

where μ_c is the permeability of the metal walls of the cavity. For $p=0$ modes, (8.95) must be multiplied by 2 and ξ_λ replaced by $2\xi_\lambda$. This expression for Q

has an intuitive physical interpretation when written in the form:

$$Q = \frac{\mu}{\mu_c} \left(\frac{V}{S\delta} \right) \times (\text{Geometrical factor}) \quad (8.96)^*$$

where V is the volume of the cavity, and S its total surface area. The Q of a cavity is evidently, apart from a geometrical factor, the ratio of the volume occupied by the fields to the volume of the conductor into which the fields penetrate because of the finite conductivity. For TM modes in cylindrical cavities the geometrical factor is

$$\frac{\left(1 + \frac{Cd}{2A}\right)}{\left(1 + \xi_\lambda \frac{Cd}{4A}\right)} \quad (8.97)$$

for $p \neq 0$, and is

$$\frac{2\left(1 + \frac{Cd}{2A}\right)}{\left(1 + \xi_\lambda \frac{Cd}{2A}\right)} \quad (8.98)$$

for $p=0$ modes. For TE modes in the cylindrical cavity the geometrical factor is somewhat more complicated, but of the same order of magnitude. For the $TM_{0,1,0}$ mode in a *circular* cylindrical cavity with fields (8.82), $\xi_\lambda = 1$ (true for all TM modes), so that the geometrical factor is 2 and Q is:

$$Q = \left(\frac{\mu}{\mu_c} \right) \frac{1}{\left(1 + \frac{d}{R}\right)} \frac{d}{\delta} \quad (8.99)^*$$

For the $TE_{1,1,1}$ mode calculation yields a geometrical factor*

$$\left(1 + \frac{d}{R}\right) \frac{\left(1 + 0.344 \frac{d^2}{R^2}\right)}{\left(1 + 0.209 \frac{d}{R} + 0.242 \frac{d^3}{R^3}\right)} \quad (8.100)$$

and a Q :

$$Q = \frac{\mu}{2\mu_c} \left(\frac{d}{\delta} \right) \frac{\left(1 + 0.344 \frac{d^2}{R^2}\right)}{\left(1 + 0.209 \frac{d}{R} + 0.242 \frac{d^3}{R^3}\right)} \quad (8.101)^*$$

Expression (8.96) for Q applies not only to cylindrical cavities but also to cavities of arbitrary shape, with an appropriate geometrical factor of the order of unity.

* Note that this factor varies from unity for $d/R = 0$ to a maximum of 2.13 at $d/R = 1.91$ and then decreases to 1.42 as $d/R \rightarrow \infty$.

The use of conservation of energy to discuss losses in a cavity has the same advantages and disadvantages as for wave guides. The Q values can be calculated but possible shifts in frequency lie outside the scope of the method. The technique of perturbation of boundary conditions, described in Section 8.6, again removes these deficiencies. In fact the analogy is so close to the wave guide situation that the answers can be deduced without performing the calculation explicitly. The unperturbed problem of the resonant frequencies of a cavity with perfectly conducting walls is specified by (8.64) or its equivalent for TE modes. Similarly, the perturbed problem involves solution of (8.67) or equivalent. A result equivalent to (8.69) evidently emerges. The difference $(\gamma_0^2 - \gamma^2)$ is proportional to $(\omega_0^2 - \omega^2)$ where now ω_0 is the unperturbed resonant frequency rather than the cutoff frequency of the wave guide and ω is the perturbed resonant frequency. Thus the analog of (8.69) takes the form,

$$\omega_0^2 - \omega^2 \approx (1+i)I \quad (8.102)$$

where I is the ratio of appropriate integrals. In the limit of $I \rightarrow 0$, the imaginary part of ω is $-iI/2\omega_0$. From (8.88) this is to be identified with $-i\omega_0/2Q$, and therefore $I = \omega_0^2/Q$. Equation (8.102) can thus be written

$$\omega^2 \approx \omega_0^2 \left[1 - \frac{(1+i)}{Q} \right] \quad (8.103)$$

where Q is the quantity defined by (8.86) and (8.92), (8.93). Damping is seen to cause equal modifications to the real and imaginary parts of ω^2 . For large Q values, the change in the resonant frequency, rather than its square, is

$$\Delta\omega \approx \text{Im } \omega \approx -\frac{\omega_0}{2Q}$$

The resonant frequency is always lowered by the presence of resistive losses. The near equality of the real and imaginary parts of the change in ω^2 is a consequence of the boundary condition (8.11) appropriate for relatively good conductors. For very lossy systems or boundaries with different surface impedances, the relative magnitude of the real and imaginary parts of the change in ω^2 can be different from that given by (8.103).

In this section, as in Section 8.6, the discussion has been confined to nondegenerate modes. References are given at the end of Section 8.6 for treatments that remedy this defect.

8.9 Earth and Ionosphere as Resonant Cavity: Schumann Resonances

A somewhat unusual example of a resonant cavity is provided by the earth itself as one boundary surface and the ionosphere as the other. The lowest resonant modes of such a system are evidently of very low frequency since

the characteristic wavelength must be of the order of magnitude of the earth's radius. In such circumstances the ionosphere and the earth both appear as conductors with real conductivities. Sea water has a conductivity of $\sigma \sim 10^9 \text{ sec}^{-1}$, while the ionosphere has $\sigma \sim 10^3 - 10^6 \text{ sec}^{-1}$. The walls of the cavity are thus far from perfectly conducting, especially the outer one. Nevertheless, we idealize the physical reality and consider as a model two perfectly conducting, concentric spheres with radii a and $b = a + h$, where a is the radius of the earth ($a \approx 6400 \text{ km}$) and h is the height of the ionosphere above the earth ($h \sim 100 \text{ km}$). Furthermore, if we are concerned with only the lowest frequencies, we can focus our attention on the TM modes, with only tangential magnetic fields.† The reason for this is that the TM modes, with a radially directed electric field, can satisfy the boundary condition of vanishing tangential electric field at $r = a$ and $r = b$ without appreciable radial variation of the fields. On the other hand, the TE modes, with only tangential electric fields, must have a radial variation of approximately half a wavelength between $r = a$ and $r = b$. The lowest frequencies for the TE modes, are therefore of the order of $\omega_{\text{TE}} \sim \pi c/h$, whereas for the lowest TM modes $\omega_{\text{TM}} \sim c/a$.

The general problem of modes in a spherical geometry is involved enough that we leave it to Chapter 16. Here we consider only TM modes and assume that the fields are independent of the azimuthal angle ϕ . The last is no real restriction; it is known from consideration of spherical harmonics that the relevant quantity is l , not m . If the radial component of \mathbf{B} vanishes and the other components do not depend on ϕ , the vanishing of the divergence of \mathbf{B} requires that only B_ϕ is nonvanishing if the fields are finite at $\theta = 0$. Faraday's law then requires $E_\phi = 0$. Thus the homogeneous Maxwell equations specify that TM modes with no ϕ dependence involve only E_r , E_θ , and B_ϕ . The two curl equations of Maxwell can be combined, after assuming a time-dependence $e^{-i\omega t}$, into

$$\frac{\omega^2}{c^2} \mathbf{B} - \nabla \times \nabla \times \mathbf{B} = 0 \quad (8.104)$$

where the permeabilities of the medium between the spheres are taken as unity. The ϕ component of (8.104) is

$$\frac{\omega^2}{c^2} (rB_\phi) + \frac{\partial^2}{\partial r^2} (rB_\phi) + \frac{1}{r^2} \frac{\partial}{\partial \theta} \left[\frac{1}{\sin \theta} \frac{\partial}{\partial \theta} (\sin \theta rB_\phi) \right] = 0 \quad (8.105)$$

The angular part of (8.105) can be transformed into

$$\frac{\partial}{\partial \theta} \left[\frac{1}{\sin \theta} \frac{\partial}{\partial \theta} (\sin \theta rB_\phi) \right] = \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial (rB_\phi)}{\partial \theta} \right) - \frac{rB_\phi}{\sin^2 \theta}$$

† For a spherical geometry the notation TE (TM) indicates the absence of radial electric (magnetic) field components.

showing, upon comparison with (3.6) or (3.9), that the θ dependence is given by the associated Legendre polynomials $P_l^m(\cos \theta)$ with $m = \pm 1$. It is natural therefore to write a product solution,

$$B_\phi(r, \theta) = \frac{u_l(r)}{r} P_l^1(\cos \theta) \quad (8.106)$$

Substitution into (8.105) yields as the differential equation for $u_l(r)$,

$$\frac{d^2 u_l(r)}{dr^2} + \left[\frac{\omega^2}{c^2} - \frac{l(l+1)}{r^2} \right] u_l(r) = 0 \quad (8.107)$$

with $l = 1, 2, \dots$ defining the angular dependence of the modes.

The characteristic frequencies emerge from (8.107) when the boundary conditions appropriate for perfectly conducting walls at $r = a$ and $r = b$ are imposed. The radial and tangential electric fields are

$$E_r = \frac{ic}{\omega r \sin \theta} \frac{\partial}{\partial \theta} (\sin \theta B_\phi) = -\frac{ic}{\omega r} l(l+1) \frac{u_l(r)}{r} P_l(\cos \theta)$$

$$E_\theta = -\frac{ic}{\omega r} \frac{\partial}{\partial r} (r B_\phi) = -\frac{ic}{\omega r} \frac{\partial u_l(r)}{\partial r} P_l^1(\cos \theta)$$

The vanishing of E_θ at $r = a$ and $r = b$ implies that the boundary condition for $u_l(r)$ is

$$\frac{du_l(r)}{dr} = 0 \quad \text{for } r = a \quad \text{and} \quad r = b \quad (8.108)$$

The solutions of (8.107) are r times the spherical Bessel functions (see Section 16.1). The boundary conditions (8.108) lead to transcendental equations for the characteristic frequencies. An example will be left as a problem, but for our present purposes a limiting case will suffice. The height h of the ionosphere is sufficiently small compared to the radius a that the limit $h/a \ll 1$ can be assumed. The $l(l+1)/r^2$ terms in (8.107) can be approximated by its value at $r = a$. The solutions of (8.107) are then $\sin(qr)$ and $\cos(qr)$, where q^2 is given by the square bracket in (8.107) evaluated at $r = a$. With the boundary conditions (8.108), the solution is

$$u_l(r) \approx A \cos[q(r-a)]$$

where $qh = n\pi$, $n = 0, 1, 2, \dots$. For $n = 1, 2, \dots$ the frequencies of the modes are evidently larger than $\omega = n\pi c/h$ and are in the domain of frequencies of the TE modes. Only for $n = 0$ are there very low frequency modes. The condition $q = 0$ is equivalent to $u_l(r) = \text{constant}$ and

$$\omega_l \approx \sqrt{l(l+1)} \frac{c}{a} \quad (8.109)$$

where the equality is exact in the limit $h/a \rightarrow 0$. The exact solution shows that to first order in h/a the correct result has a replaced by $(a + \frac{1}{2}h)$. The fields are $E_\theta = 0$, $r^2 E_r \propto P_l(\cos \theta)$, $r B_\phi \propto P_l^1(\cos \theta)$.

The resonant frequencies (8.109) are called *Schumann resonances*.[†] They are extremely low frequencies: with $a = 6400$ km, the first five resonant frequencies are $\omega_l/2\pi = 10.6, 18.3, 25.8, 33.4, 40.9$ Hz. Schumann resonances manifest themselves as peaks in the noise power spectrum of extremely low frequencies propagating around the earth. Lightning bolts, containing a wide spectrum of frequencies, act as sources of radial electric fields. The frequency components near the Schumann resonances are propagated preferentially because they are normal modes of the earth-ionosphere cavity. The first definitive observations of these peaks in the noise power spectrum were made in 1960,[‡] although there is evidence that Nikola Tesla *may* have observed them before 1900.[§] A typical noise power spectrum is shown in Fig. 8.9. The resonances are clearly visible. They shift slightly and change shape from day to day, but have average linear frequencies of 8, 14, 20, 26, 32, 37, and 43 Hz for the first seven peaks. These frequencies are given quite closely by $5.8\sqrt{l(l+1)}$ Hz, the coefficient being 0.78 times $c/2\pi a (= 7.46$ Hz). The lack of precise agreement is not surprising, since, as already noted, the assumption of perfectly conducting walls is rather far from the truth. The Q values are estimated to be of the order of 4 to 10 for the first few resonances, corresponding to rather heavy damping. The effect of the damping on a resonant frequency is in the right direction to account for the differences between the observed values and (8.109), but the simple shift implied by (8.103) is only about half of what is observed. The $\sqrt{l(l+1)}$ variation of the resonant frequencies is, however, quite striking.

The simple picture of a resonant cavity with well-defined, but lossy, walls accounts for the main features of the Schumann resonances, although failing in some quantitative aspects. More realistic and detailed models and discussion of the observations can be found in a review by Galejs,^{||} as well as her monograph, *Galejs*. The use of wave guide and resonant cavity concepts in the treatment of propagation of electromagnetic waves around the earth is discussed in the books by *Budden* and *Wait* listed at the end of this chapter. One curiosity may be

Fig. 8.9 Typical noise power spectrum at low frequencies (integrated over 30 sec), observed at Lavangsdalen, Norway on June 19, 1965. The prominent Schumann resonances at 8, 14, 20, and 26 Hz, plus peaks at 32, 37, and 43 Hz as well as smaller structure are visible [after A. Egeland and T. R. Larsen, *Physica Norvegica* 2, 85 (1967)].

permitted here. On July 9, 1962 a nuclear explosion was detonated at high altitude over Johnston Island in the Pacific. One consequence of this test was to create observable alterations in the ionosphere and radiation belts on a worldwide scale. Sudden decreases of from 3–5% in Schumann resonant frequencies were observed in France and at other stations immediately after the explosion, the changes decaying away over a period of several hours. This is documented in Fig. 17 of the paper by Galejs.

8.10 Dielectric Wave Guides

In Section 8.2–8.6 we considered wave guides made of hollow metal cylinders with fields only inside the hollow. Other guiding structures are possible. The parallel-wire transmission line is an example. The general requirement for a guide of electromagnetic waves is that there be a flow of energy only along the guiding structure and not perpendicular to it. This means that the fields will be appreciable only in the immediate neighborhood of the guiding structure. For

hollow wave guides these requirements are satisfied in a trivial way. But for an open structure like the parallel-wire line the fields extend somewhat away from the conductors, falling off like ρ^{-2} for the TEM mode, and exponentially for higher modes.

A dielectric cylinder, such as shown in Fig. 8.10, can serve as a wave guide, with some properties very similar to those of a hollow metal guide if its dielectric constant is large enough. There are, however, characteristic differences which arise because of the very different boundary conditions to be satisfied at the surface of the cylinder. The general considerations of Section 8.2 still apply, except that the transverse behavior of the fields is governed by two equations like (8.19), one for inside the cylinder and one for outside:

INSIDE

$$\left[\nabla_t^2 + \left(\mu_1 \epsilon_1 \frac{\omega^2}{c^2} - k^2 \right) \right] \begin{Bmatrix} \mathbf{E} \\ \mathbf{B} \end{Bmatrix} = 0 \quad (8.110)$$

OUTSIDE

$$\left[\nabla_t^2 + \left(\mu_0 \epsilon_0 \frac{\omega^2}{c^2} - k^2 \right) \right] \begin{Bmatrix} \mathbf{E} \\ \mathbf{B} \end{Bmatrix} = 0 \quad (8.111)$$

Both dielectric (μ_1, ϵ_1) and surrounding medium (μ_0, ϵ_0) are assumed to be uniform and isotropic in their properties. The axial propagation constant k must be the same inside and outside the cylinder in order to satisfy boundary conditions at all points on the surface at all times.

In the usual way, inside the dielectric cylinder the transverse Laplacian of the fields must be negative so that the constant

$$\gamma^2 = \mu_1 \epsilon_1 \frac{\omega^2}{c^2} - k^2 \quad (8.112)$$

is positive. Outside the cylinder, however, the requirement of no transverse flow of energy demands that the fields fall off exponentially. (There is no TEM mode

Fig. 8.10 Section of dielectric wave guide.

for a dielectric guide.) Consequently, the quantity in (8.111) equivalent to γ^2 must be negative. Therefore we define a quantity β^2 :

$$\beta^2 = k^2 - \mu_0 \epsilon_0 \frac{\omega^2}{c^2} \quad (8.113)$$

and demand that acceptable wave guide solutions have β^2 positive (β real).

The oscillatory solutions (inside) must be matched to the exponential solutions (outside) at the boundary of the dielectric cylinder. The boundary conditions are continuity of normal \mathbf{B} and \mathbf{D} and tangential \mathbf{E} and \mathbf{H} , rather than the vanishing of normal \mathbf{B} and tangential \mathbf{E} appropriate for hollow conductors. Because of the more involved boundary conditions the types of fields do not separate into TE and TM modes, except in special circumstances such as azimuthal symmetry in circular cylinders, to be discussed below. In general, axial components of both \mathbf{E} and \mathbf{B} exist. Such waves are sometimes designated as HE modes.

To illustrate some of the features of the dielectric wave guide we consider a circular cylinder of radius a consisting of nonpermeable dielectric with dielectric constant ϵ_1 in an external nonpermeable medium with dielectric constant ϵ_0 . As a simplifying assumption we take the fields to have *no azimuthal variation*. Then in cylindrical coordinates the radial equations for E_z or B_z are Bessel's equations:

$$\left. \begin{aligned} \left(\frac{d^2}{d\rho^2} + \frac{1}{\rho} \frac{d}{d\rho} + \gamma^2 \right) \psi &= 0, & \rho \leq a \\ \left(\frac{d^2}{d\rho^2} + \frac{1}{\rho} \frac{d}{d\rho} - \beta^2 \right) \psi &= 0, & \rho > a \end{aligned} \right\} \quad (8.114)$$

The solution, satisfying the requirements of finiteness at the origin and at infinity, is found from Section 3.7 to be:

$$\psi = \begin{cases} J_0(\gamma\rho), & \rho \leq a \\ AK_0(\beta\rho), & \rho > a \end{cases} \quad (8.115)$$

The other components of \mathbf{E} and \mathbf{B} can be found from (8.23) and (8.24) when the relative amounts of E_z and B_z are known. With no ϕ dependence the fields reduce to

INSIDE

$$\left. \begin{aligned} B_\rho &= \frac{ik}{\gamma^2} \frac{\partial B_z}{\partial \rho}, & B_\phi &= \frac{i\epsilon_1 \omega}{\gamma^2 c} \frac{\partial E_z}{\partial \rho} \\ E_\phi &= -\frac{\omega}{ck} B_\rho, & E_\rho &= \frac{ck}{\epsilon_1 \omega} B_\phi \end{aligned} \right\} \quad (8.116)$$

and similar expressions for $\rho > a$. The fact that the fields arrange themselves in two groups, (B_ρ, E_ϕ) depending on B_z , and (B_ϕ, E_ρ) depending on E_z , suggests that we attempt to obtain solutions of the TE or TM type, as for the metal wave

guides. For the TE modes, the fields are explicitly

$$\left. \begin{aligned} B_z &= J_0(\gamma\rho) \\ B_\rho &= -\frac{ik}{\gamma} J_1(\gamma\rho) \\ E_\phi &= \frac{i\omega}{c\gamma} J_1(\gamma\rho) \end{aligned} \right\} \quad \rho \leq a \quad (8.117)$$

and

$$\left. \begin{aligned} B_z &= AK_0(\beta\rho) \\ B_\rho &= \frac{ikA}{\beta} K_1(\beta\rho) \\ E_\phi &= -\frac{i\omega A}{c\beta} K_1(\beta\rho) \end{aligned} \right\} \quad \rho > a \quad (8.118)$$

These fields must satisfy the standard boundary conditions at $\rho = a$. This leads to the two conditions,

$$\left. \begin{aligned} AK_0(\beta a) &= J_0(\gamma a) \\ -\frac{A}{\beta} K_1(\beta a) &= \frac{J_1(\gamma a)}{\gamma} \end{aligned} \right\} \quad (8.119)$$

Upon elimination of the constant A we obtain the determining equations for γ , β , and therefore k :

$$\left. \begin{aligned} \frac{J_1(\gamma a)}{\gamma J_0(\gamma a)} + \frac{K_1(\beta a)}{\beta K_0(\beta a)} &= 0 \\ \gamma^2 + \beta^2 &= (\epsilon_1 - \epsilon_0) \frac{\omega^2}{c^2} \end{aligned} \right\} \quad (8.120)$$

The two parts of the first equation in (8.120) are plotted in Fig. 8.11, with the two curves superposed according to the second equation in (8.120). The frequency is assumed to be high enough that two modes, marked by the circles at the intersections of the two curves, exist. The vertical asymptotes are given by the roots of $J_0(x) = 0$. If the maximum value of γa is smaller than the first root ($x_{01} = 2.405$), there can be no intersection of the two curves for real β . Hence the lowest “cutoff” frequency for $TE_{0,n}$ waves is given by

$$\omega_{01} = \frac{2.405c}{\sqrt{\epsilon_1 - \epsilon_0} a} \quad (8.121)$$

At this frequency $\beta^2 = 0$, but the axial wave number k is still real and equal to its free-space value $\sqrt{\epsilon_0} \omega/c$. Immediately below this “cutoff” frequency, the system no longer acts as a guide but as an antenna, with energy being radiated radially.

Fig. 8.11 Graphical determination of the axial propagation constant for a dielectric wave guide.

For frequencies well above cutoff, β and k are of the same order of magnitude and are large compared to γ provided ϵ_1 and ϵ_0 are not nearly equal.

For TM modes, the first equation in (8.120) is replaced by

$$\frac{J_1(\gamma a)}{\gamma J_0(\gamma a)} + \frac{\epsilon_0}{\epsilon_1} \frac{K_1(\beta a)}{\beta K_0(\beta a)} = 0 \quad (8.122)$$

It is evident that all the qualitative features shown in Fig. 8.11 are retained for the TM waves. The lowest “cutoff” frequency for $TM_{0,n}$ waves is clearly the same as for $TE_{0,n}$ waves. For $\epsilon_1 \gg \epsilon_0$, (8.122) and Fig. 8.11 show that, except perhaps for the mode with the largest γ (smallest β), the propagation constants are determined by $J_1(\gamma a) \approx 0$. This is just the determining equation for TE waves in a metallic wave guide. The reason for the equivalence of the TM modes in a dielectric guide and the TE modes in a hollow metallic guide can be traced to the symmetry of the Maxwell equations under the interchange of \mathbf{E} and \mathbf{B} (with appropriate sign changes and factors of $\sqrt{\mu\epsilon}$), plus the correspondence between the vanishing of normal \mathbf{B} at the metallic surface and the almost vanishing of normal \mathbf{E} at the dielectric surface (because of continuity of normal \mathbf{D} with $\epsilon_1 \gg \epsilon_0$).

Fig. 8.12 Radial variation of fields of $TE_{0,1}$ mode in dielectric guide. For $\epsilon_1 \gg \epsilon_0$, the fields are confined mostly inside the dielectric.

If $\epsilon_1 \gg \epsilon_0$, then from (8.112) and (8.113) it is clear that the outside decay constant β is much larger than γ , except near cutoff. This means that the fields do not extend appreciably outside the dielectric cylinder. Figure 8.12 shows qualitatively the behavior of the fields for the $TE_{0,1}$ mode. The other modes behave similarly. As mentioned earlier, modes with azimuthal dependence to the fields have longitudinal components of both \mathbf{E} and \mathbf{B} . Although the mathematics is somewhat more involved (see Problem 8.8), the qualitative features of propagation—short wavelength along the cylinder, rapid decrease of fields outside the cylinder, etc.—are the same as for the circularly symmetric modes.

Dielectric wave guides have not been used for microwave propagation, except for special applications. One reason is that it is difficult to obtain suitable dielectrics with sufficiently low losses at microwave frequencies. In some applications at optical frequencies very fine dielectric filaments, each coated with a thin layer of material of much lower index of refraction, are closely bundled together to form image-transfer devices.[†] The filaments are sufficiently small in diameter (~ 10 microns) that wave-guide concepts are useful, even though the propagation is usually a mixture of several modes.

8.11 Expansion in Normal Modes, Fields Generated by a Localized Source in Guide

For a given wave guide cross section and frequency ω the electromagnetic fields in a hollow guide are described by an infinite set of characteristic or normal modes consisting of TE and TM waves, each with its characteristic cutoff frequency. For any given finite frequency only a finite number of the modes can

[†] See B. O'Brien, *Physics Today*, **13**, 52 (1960) for an early qualitative discussion and N. S. Kapany and J. J. Burke, *Optical Waveguides*, Academic, New York (1972) for analytic and practical treatments.

propagate; the rest are cutoff or evanescent modes. Far away from any source, obstacle or aperture in the guide the fields are relatively simple, with only the propagating modes (often just one) present with appreciable amplitude. Near a source or obstacle, however, many modes, both propagating and evanescent, must be superposed in order to describe the fields correctly. The cutoff modes have sizable amplitudes only in the neighborhood of the source or obstacle; their effects decay away over distances measured by the reciprocal of the imaginary part of their wave number. A typical practical problem concerning a source, obstacle, or aperture in a wave guide thus involves as accurate a solution as is possible for the fields in the vicinity of the source, etc., the expansion of those fields in terms of all the normal modes of the guide, and a determination of the amplitudes for the one or more propagating modes that will describe the fields far away.

(a) *Orthonormal Modes*

To facilitate the handling of the expansion of fields in the normal modes, it is useful to standardize the notation for the fields of a given mode, treating TE and TM modes on an equal footing and introducing a convenient normalization. Let the subscript λ or μ denote a given mode. One may think of $\lambda = 1, 2, 3, \dots$ indicating the modes arranged in some arbitrary order, of increasing cutoff frequency, for example. The subscript λ also conveys whether the mode is a TE or TM wave. The fields for the λ mode propagating in the *positive* z direction are written

$$\begin{aligned} \mathbf{E}_{\lambda}^{(+)}(x, y, z) &= [\mathbf{E}_{\lambda}(x, y) + \mathbf{E}_{z\lambda}(x, y)]e^{ik_{\lambda}z} \\ \mathbf{H}_{\lambda}^{(+)}(x, y, z) &= [\mathbf{H}_{\lambda}(x, y) + \mathbf{H}_{z\lambda}(x, y)]e^{ik_{\lambda}z} \end{aligned} \quad (8.123)$$

where \mathbf{E}_{λ} , \mathbf{H}_{λ} are the transverse fields given by (8.31) and (8.33) and $\mathbf{E}_{z\lambda}$, $\mathbf{H}_{z\lambda}$ are the longitudinal fields. The wave number k_{λ} is given by (8.37) and is taken to be real and positive for propagating modes in lossless guides (and purely imaginary, $k_{\lambda} = i\varphi_{\lambda}$, for cutoff modes). A time dependence $e^{-i\omega t}$ is, of course, understood. For a wave propagating in the *negative* z direction the fields are

$$\begin{aligned} \mathbf{E}_{\lambda}^{(-)} &= [\mathbf{E}_{\lambda} - \mathbf{E}_{z\lambda}]e^{-ik_{\lambda}z} \\ \mathbf{H}_{\lambda}^{(-)} &= [-\mathbf{H}_{\lambda} + \mathbf{H}_{z\lambda}]e^{-ik_{\lambda}z} \end{aligned} \quad (8.124)$$

The pattern of signs in (8.124) compared to (8.123) can be understood from the need to satisfy $\nabla \cdot \mathbf{E} = \nabla \cdot \mathbf{H} = 0$ for each direction of propagation and the requirement of positive power flow in the direction of propagation. The overall phase of the fields in (8.124) relative to (8.123) is arbitrary. The choice taken here makes the transverse electric field at $z = 0$ the same for both directions of propagation, just as is done for the voltage waves on transmission lines.

A convenient normalization for the fields in (8.123) and (8.124) is afforded by

taking the *transverse electric fields* $\mathbf{E}_\lambda(x, y)$ to be *real*, and requiring that

$$\int \mathbf{E}_\lambda \cdot \mathbf{E}_\mu \, da = \delta_{\lambda\mu} \quad (8.125)$$

where the integral is over the cross-sectional area of the guide. [The orthogonality of the different modes is taken for granted here. The proof is left as a problem (Problem 8.9), as is the derivation of the other normalization integrals listed below.] From the relation (8.31) between electric and magnetic fields it is evident that (8.125) implies

$$\int \mathbf{H}_\lambda \cdot \mathbf{H}_\mu \, da = \frac{1}{Z_\lambda^2} \delta_{\lambda\mu} \quad (8.126)$$

and that the time-averaged power flow in the λ th mode is

$$\frac{c}{8\pi} \int (\mathbf{E}_\lambda \times \mathbf{H}_\mu) \cdot \mathbf{e}_3 \, da = \frac{c}{8\pi Z_\lambda} \delta_{\lambda\mu} \quad (8.127)$$

It can also be shown that if (8.125) holds the longitudinal components are normalized according to

$$\begin{aligned} \text{TM WAVES:} \quad & \int E_{z\lambda} E_{z\mu} \, da = \frac{-\gamma_\lambda^2}{k_\lambda^2} \delta_{\lambda\mu} \\ \text{TE WAVES:} \quad & \int H_{z\lambda} H_{z\mu} \, da = \frac{-\gamma_\lambda^2}{k_\lambda^2 Z_\lambda^2} \delta_{\lambda\mu} \end{aligned} \quad (8.128)$$

As an explicit example of these normalized fields we list the transverse electric fields and also H_z and E_z of the TE and TM modes in a rectangular guide. The mode index λ is actually two indices (m, n). The normalized fields are

$$\begin{aligned} \text{TM WAVES:} \quad E_{xmn} &= \frac{2\pi m}{\gamma_{mn} a \sqrt{ab}} \cos\left(\frac{m\pi x}{a}\right) \sin\left(\frac{n\pi y}{b}\right) \\ E_{ymn} &= \frac{2\pi n}{\gamma_{mn} b \sqrt{ab}} \sin\left(\frac{m\pi x}{a}\right) \cos\left(\frac{n\pi y}{b}\right) \\ E_{zmn} &= \frac{-2i\gamma_{mn}}{k_\lambda \sqrt{ab}} \sin\left(\frac{m\pi x}{a}\right) \sin\left(\frac{n\pi y}{b}\right) \end{aligned} \quad (8.129)$$

$$\begin{aligned} \text{TE WAVES:} \quad E_{xmn} &= \frac{-2\pi n}{\gamma_{mn} b \sqrt{ab}} \cos\left(\frac{m\pi x}{a}\right) \sin\left(\frac{n\pi y}{b}\right) \\ E_{ymn} &= \frac{2\pi m}{\gamma_{mn} a \sqrt{ab}} \sin\left(\frac{m\pi x}{a}\right) \cos\left(\frac{n\pi y}{b}\right) \\ H_{zmn} &= \frac{-2i\gamma_{mn}}{k_\lambda Z_\lambda \sqrt{ab}} \cos\left(\frac{m\pi x}{a}\right) \cos\left(\frac{n\pi y}{b}\right) \end{aligned} \quad (8.130)$$

with γ_{mn} given by (8.43). The transverse magnetic field components can be obtained by means of (8.31). For TM modes, the lowest value of m and n is unity, but for TE modes, $m=0$ or $n=0$ is allowed. If $m=0$ or $n=0$, the normalization must be amended by multiplication of the right-hand sides of (8.130) by $1/\sqrt{2}$.

(b) *Expansion of Arbitrary Fields*

An arbitrary electromagnetic field with time dependence $e^{-i\omega t}$ can be expanded in terms of the normal mode fields (8.123) and (8.124).† It is useful to keep track explicitly of the total fields propagating in the two directions. Thus the arbitrary fields are written in the form

$$\mathbf{E} = \mathbf{E}^{(+)} + \mathbf{E}^{(-)}, \quad \mathbf{H} = \mathbf{H}^{(+)} + \mathbf{H}^{(-)} \quad (8.131)$$

where

$$\mathbf{E}^{(\pm)} = \sum_{\lambda} A_{\lambda}^{(\pm)} \mathbf{E}_{\lambda}^{(\pm)}, \quad \mathbf{H}^{(\pm)} = \sum_{\lambda} A_{\lambda}^{(\pm)} \mathbf{H}_{\lambda}^{(\pm)} \quad (8.132)$$

Specification of the expansion coefficients $A_{\lambda}^{(+)}$ and $A_{\lambda}^{(-)}$ determines the fields everywhere in the guide. These may be found from boundary or source conditions in a variety of ways. Here is a useful theorem:

The fields everywhere in the guide are determined uniquely by specification of the transverse components of \mathbf{E} and \mathbf{H} in a plane, $z = \text{constant}$.

Proof: There is no loss in generality in choosing the plane at $z = 0$. Then from (8.131), (8.132), and (8.123), (8.124), the transverse fields are

$$\begin{aligned} \mathbf{E}_t &= \sum_{\lambda} (A_{\lambda}^{(+)} + A_{\lambda}^{(-)}) \mathbf{E}_{\lambda}, \\ \mathbf{H}_t &= \sum_{\lambda} (A_{\lambda}^{(+)} - A_{\lambda}^{(-)}) \mathbf{H}_{\lambda}. \end{aligned} \quad (8.133)$$

If the scalar product of both sides of the first equation is formed with \mathbf{E}_{λ} and an integration over the cross section of the guide is performed, the orthogonality condition (8.125) implies

$$A_{\lambda}^{(+)} + A_{\lambda}^{(-)} = \int \mathbf{E}_{\lambda} \cdot \mathbf{E}_t \, da$$

Similarly the second equation, with (8.126), yields

$$A_{\lambda}^{(+)} - A_{\lambda}^{(-)} = Z_{\lambda}^{-2} \int \mathbf{H}_{\lambda} \cdot \mathbf{H}_t \, da$$

† We pass over the mathematical problem of the *completeness* of the set of normal modes, and also only remark that more *general* time dependences can be handled by Fourier superposition.

The coefficients $A_{\lambda}^{(\pm)}$ are therefore given by

$$A_{\lambda}^{(\pm)} = \frac{1}{2} \int (\mathbf{E}_{\lambda} \cdot \mathbf{E}_t \pm Z_{\lambda}^2 \mathbf{H}_{\lambda} \cdot \mathbf{H}_t) da \quad (8.134)$$

This shows that if \mathbf{E}_t and \mathbf{H}_t are given at $z = 0$, the coefficients in the expansion (8.131) and (8.132) are determined. The completeness of the normal mode expansion assures the uniqueness of the representation for all z .

(c) *Fields Generated by a Localized Source*

The fields in a wave guide may be generated by a localized source, as shown schematically in Fig. 8.13. The current density $\mathbf{J}(\mathbf{x}, t)$ is assumed to vary in time as $e^{-i\omega t}$. Because of the oscillating current, fields propagate to the left and to the right. Outside the source, at and to the right of the surface S_+ , say, there will be only fields varying as $e^{ik_{\lambda}z}$ and the electric field can be expressed as

$$\mathbf{E} = \mathbf{E}^{(+)} = \sum_{\lambda} A_{\lambda}^{(+)} \mathbf{E}_{\lambda}^{(+)} \quad (8.135)$$

with a corresponding expression for \mathbf{H} . On and to the left of the surface S_- the fields all vary as $e^{-ik_{\lambda}z}$ and the electric field is

$$\mathbf{E} = \mathbf{E}^{(-)} = \sum_{\lambda} A_{\lambda}^{(-)} \mathbf{E}_{\lambda}^{(-)} \quad (8.136)$$

To determine the coefficients $A_{\lambda}^{(\pm)}$ in terms of \mathbf{J} , we consider a form of the energy flow equation of Poynting's theorem. The identity,

$$\frac{c}{4\pi} \nabla \cdot (\mathbf{E} \times \mathbf{H}_{\lambda}^{(\pm)} - \mathbf{E}_{\lambda}^{(\pm)} \times \mathbf{H}) = \mathbf{J} \cdot \mathbf{E}_{\lambda}^{(\pm)} \quad (8.137)$$

follows from the sourcefree Maxwell equations for $\mathbf{E}_{\lambda}^{(\pm)}$, $\mathbf{H}_{\lambda}^{(\pm)}$, and the Maxwell equations with source satisfied by \mathbf{E} and \mathbf{H} . Integration of (8.137) over a volume

Fig. 8.13 Schematic representation of a localized source in a wave guide. The walls of the guide, together with the planes S_+ and S_- , define the volume containing the source.

V bounded by a closed surface S leads, via the divergence theorem, to the result,

$$\frac{c}{4\pi} \int_S (\mathbf{E} \times \mathbf{H}_\lambda^{(\pm)} - \mathbf{E}_\lambda^{(\pm)} \times \mathbf{H}) \cdot \mathbf{n} \, da = \int_V \mathbf{J} \cdot \mathbf{E}_\lambda^{(\pm)} \, d^3x \quad (8.138)$$

where \mathbf{n} is an outwardly directed normal. The volume V is now chosen to be the volume bounded by the inner walls of the guide and two surfaces S_+ and S_- of Fig. 8.13. With the assumption of perfectly conducting walls containing no sources or apertures in them, the part of the surface integral over the walls vanishes. Only the integrals over S_+ and S_- contribute. For definiteness, we choose the *lower* sign in (8.138) and substitute from (8.135) for the integral over S_+ :

$$\frac{c}{4\pi} \int_{S_+} = \frac{c}{4\pi} \sum_{\lambda'} A_{\lambda'}^{(+)} \int_{S_+} \mathbf{e}_3 \cdot (\mathbf{E}_{\lambda'}^{(+)} \times \mathbf{H}_\lambda^{(-)} - \mathbf{E}_\lambda^{(-)} \times \mathbf{H}_{\lambda'}^{(+)}) \, da$$

With the fields (8.123) and (8.124) and the normalization (8.127), this becomes

$$\frac{c}{4\pi} \int_{S_+} = -\frac{c}{2\pi Z_\lambda} A_{\lambda}^{(+)} \quad (8.139)$$

The part of the surface integral in (8.138) from S_- is

$$\frac{c}{4\pi} \int_{S_-} = -\frac{c}{4\pi} \sum_{\lambda'} A_{\lambda'}^{(-)} \int_{S_-} \mathbf{e}_3 \cdot (\mathbf{E}_{\lambda'}^{(-)} \times \mathbf{H}_\lambda^{(-)} - \mathbf{E}_\lambda^{(-)} \times \mathbf{H}_{\lambda'}^{(-)}) \, da$$

which can easily be shown to vanish. For the choice of the lower sign in (8.138), therefore, only the surface S_+ gives a contribution to the left-hand side. Similarly, for the upper sign, only the integral over S_- contributes. It yields (8.139), but with $A_{\lambda}^{(-)}$ instead of $A_{\lambda}^{(+)}$. With (8.139) for the left-hand side of (8.138), the coefficients $A_{\lambda}^{(\pm)}$ are determined to be

$$A_{\lambda}^{(\pm)} = -\frac{2\pi Z_\lambda}{c} \int_V \mathbf{J} \cdot \mathbf{E}_\lambda^{(\mp)} \, d^3x \quad (8.140)$$

where the field $\mathbf{E}_\lambda^{(\mp)}$ of the normal mode λ is normalized according to (8.125). Note that the amplitude for propagation in the *positive* z direction comes from integration of the scalar product of the current with the mode field describing propagation in the *negative* z direction, and vice versa.

It is a simple matter to allow for the presence of apertures (acting as sources or sinks) in the walls of the guide between the two planes S_+ and S_- . Inspection of (8.138) shows that in such circumstances (8.140) is modified to read

$$A_{\lambda}^{(\pm)} = \frac{Z_\lambda}{2} \int_{\text{apertures}} (\mathbf{E} \times \mathbf{H}_\lambda^{(\mp)}) \cdot \mathbf{n} \, da - \frac{2\pi Z_\lambda}{c} \int_V \mathbf{J} \cdot \mathbf{E}_\lambda^{(\mp)} \, d^3x \quad (8.141)$$

where \mathbf{E} is the *exact* tangential electric field in the apertures and \mathbf{n} is *outwardly* directed.

The application of (8.140) to examples of the excitation of waves in guides is

left to the problems at the end of the chapter. In the next chapter (Section 9.5) the question of a source that is small compared to a wavelength is considered, and the approximation of (8.140) by the coupling of the electric and magnetic dipole moments of the source to the electric and magnetic fields of the λ th mode is derived. The coupling of wave guides by small apertures is also discussed in Section 9.5. The subject of sources and excitation of oscillations in wave guides and cavities is of considerable practical importance in microwave engineering. There is a voluminous literature on the topic. One of the best recent references is the book by *Collin*, Chapters 5 and 7.

8.12 Reflection and Transmission by Plane Diaphragms, Variational Approximation

Discontinuities in the form of obstacles, dielectric slabs, diaphragms and apertures in the walls occur in the practical use of wave guides as carriers of electromagnetic energy and phase information in microwave systems. The great research effort put into radar during the Second World War led to the development of sophisticated mathematical techniques for the solution of many of these complicated boundary-value problems. We illustrate here one of the simpler, although still important, classes of discontinuities, plane diaphragms or windows of negligible thickness oriented transverse to the axis of the guide. The exact solution of such problems is generally possible only by resort to numerical computation. Approximation methods, notably the variational technique developed by Julian Schwinger,[†] can, however, yield reliable answers with modest effort.

The United States radar research during 1940–45 is documented in the Massachusetts Institute of Technology Radiation Laboratory Series, published by McGraw-Hill Book Company, Inc., New York. The general physical principles of microwave circuits are covered in the book by *Montgomery, Dicke, and Purcell*, while a compendium of results on discontinuities in wave guides is provided by the volume by *Marcuvitz*. These and other references are listed at the end of the chapter.

The special type of discontinuity to be considered is shown in Fig. 8.14. The somewhat fanciful set of openings in the diaphragm serve to remind that the argument is general, within the framework of a plane transverse window of negligible thickness. If the wave guide is operated at a frequency such that only the lowest modes can propagate, it is sufficient to consider, far away from the

[†] As has occurred with other seminal work by Schwinger, the wartime treatment of wave guides existed for a long period only in the form of unpublished, and generally unavailable, lecture notes. This has been remedied in part after a delay of nearly a quarter of a century, by the publication in book form of the notes from lectures at the M.I.T. Radiation Laboratory, listed in the references at the end of this chapter.

Fig. 8.14 Discontinuity in the form of a plane transverse diaphragm of negligible thickness. Side view on the left and plan view on the right.

discontinuity, only the incident, reflected and transmitted fields of that lowest mode. The description of the effects of the discontinuity can be made in the language of transmission line theory, with the diaphragm being equivalent to a frequency-dependent shunt impedance. Near the diaphragm it is of course necessary to include the effects of the evanescent modes in order to satisfy the boundary conditions at the diaphragm.

With the assumption that only the lowest mode ($\lambda = 1$) can propagate and that there is incident from the left a wave of unit amplitude (in the sense of the previous section) in the lowest mode, the *electric field* for $z < 0$ can be written

$$\mathbf{E} = \mathbf{E}_1^{(+)} + R\mathbf{E}_1^{(-)} + \sum_{\lambda=2}^{\infty} A_{\lambda}^{(-)} \mathbf{E}_{\lambda}^{(-)} \quad (8.142)$$

with a similar expression for the magnetic field \mathbf{H} . The mode fields (8.123) and (8.124) have been separated explicitly into the propagating and cutoff parts. The fields $\mathbf{E}_1^{(\pm)}$ vary in z as $e^{\pm ikz}$, while the fields $\mathbf{E}_{\lambda}^{(-)}$ with $\lambda \geq 2$ vary as $e^{\kappa_{\lambda} z}$ and so are appreciable only near $z=0$. For $z > 0$, only waves moving in the positive z direction can occur. The *electric field* for $z > 0$ is thus

$$\mathbf{E} = T\mathbf{E}_1^{(+)} + \sum_{\lambda=2}^{\infty} A_{\lambda}^{(+)} \mathbf{E}_{\lambda}^{(+)} \quad (8.143)$$

The coefficients R and T are the amplitudes of the reflected and transmitted waves in the lowest mode. If the walls of the guide and the surfaces of the diaphragm are perfectly conducting, there are no losses in the system. This means that $1 + R = T$. Verification of this result comes from formally evaluating the coefficients in (8.142) and (8.143). Scalar multiplication of both sides of (8.142) with the transverse mode field \mathbf{E}_{λ} and integration over the cross-sectional area of the guide at $z=0^-$ gives

$$1 + R = \int_{z=0^-} \mathbf{E} \cdot \mathbf{E}_1 \, da$$

$$A_{\lambda}^{(-)} = \int_{z=0^-} \mathbf{E} \cdot \mathbf{E}_{\lambda} \, da \quad (\lambda > 1)$$

because of the orthogonality relation (8.125). Similarly (8.143) yields

$$T = \int_{z=0^+} \mathbf{E} \cdot \mathbf{E}_1 da$$

$$A_\lambda^{(+)} = \int_{z=0^+} \mathbf{E} \cdot \mathbf{E}_\lambda da \quad (\lambda > 1)$$

If the diaphragm surfaces are perfectly conducting, the tangential electric field vanishes except in the apertures and the above integrals extend only over the area of those apertures. Because of the continuity of the tangential electric field in the apertures at $z=0$, there is no difference between an integral at $z=0^+$ and one at $z=0^-$. As a consequence the coefficients are given by

$$1 + R = T = \int_{\text{apertures}} \mathbf{E} \cdot \mathbf{E}_1 da \quad (8.144)$$

$$A_\lambda^{(+)} = A_\lambda^{(-)} = \int_{\text{apertures}} \mathbf{E} \cdot \mathbf{E}_\lambda da \quad (8.145)$$

If the exact electric field in the aperture, or some reasonable approximation to it, can be found, (8.144) can be used to determine the amplitudes of the reflected and transmitted waves. In some circumstances static fields and conformal mapping techniques can be utilized. Any of the approximation schemes are enhanced when combined with the stationary or variational expressions of Schwinger. These expressions replace the direct form (8.144) by a more complicated result involving a sum over all the evanescent modes, but stationary with respect to variations of the fields away from their true values, and so suitable for use with relatively poor trial values of the fields. As with many worthwhile things, the derivation is not immediately obvious to the uninitiated. We begin by considering the explicit form of the boundary conditions on the tangential electric and magnetic fields in the apertures. Tangential \mathbf{E} and \mathbf{H} are continuous there. With the mode fields (8.123) and (8.124) and the expansions (8.142) and (8.143), the continuity of the transverse electric field appears as

$$(1 + R)\mathbf{E}_1 + \sum_{\lambda=2}^{\infty} A_\lambda^{(-)} \mathbf{E}_\lambda = T\mathbf{E}_1 + \sum_{\lambda=2}^{\infty} A_\lambda^{(+)} \mathbf{E}_\lambda \quad (8.146)$$

In view of (8.144) and (8.145) this is an obvious equality, as should be expected. It is written out to contrast it with the corresponding equation for the transverse magnetic field:

$$(1 - R)\mathbf{H}_1 - \sum_{\lambda=2}^{\infty} A_\lambda^{(-)} \mathbf{H}_\lambda = T\mathbf{H}_1 + \sum_{\lambda=2}^{\infty} A_\lambda^{(+)} \mathbf{H}_\lambda \quad (8.147)$$

Equation (8.146) holds over the whole cross-sectional area of the guide because the expansion coefficients (8.144) and (8.145) assure that the tangential field vanishes on the surface of the diaphragm, but (8.147) holds only in the

apertures. On either surface of the diaphragm surface currents flow, and there is no requirement of continuity for tangential \mathbf{H} .

From (8.31), the transverse mode field \mathbf{H}_λ can be written as

$$\mathbf{H}_\lambda = Y_\lambda \mathbf{e}_3 \times \mathbf{E}_\lambda \quad (8.148)$$

where $Y_\lambda = Z_\lambda^{-1}$ is the *wave admittance* and is given by the reciprocal of (8.32) with $k = k_\lambda$. The statement of continuity of tangential \mathbf{H} in the apertures, (8.147), can thus be written in terms of the electric fields:

$$(1-R)Y_1\mathbf{E}_1 - \sum_{\lambda=2}^{\infty} Y_\lambda A_\lambda^{(-)}\mathbf{E}_\lambda = TY_1\mathbf{E}_1 + \sum_{\lambda=2}^{\infty} Y_\lambda A_\lambda^{(+)}\mathbf{E}_\lambda$$

Use of the relation $T = 1 + R$ and (8.145) allows this to be cast into the form,

$$-2RY_1\mathbf{E}_1 = 2 \sum_{\lambda=2}^{\infty} Y_\lambda \mathbf{E}_\lambda \int_{\text{apertures}} \mathbf{E} \cdot \mathbf{E}_\lambda \, da \quad (8.149)$$

The variational result follows in two steps. The first is scalar multiplication of both sides of (8.149) with the exact field \mathbf{E} and integration over the apertures. With (8.144) this yields

$$-2R(1+R)Y_1 = 2 \sum_{\lambda=2}^{\infty} Y_\lambda \left[\int_{\text{apertures}} \mathbf{E} \cdot \mathbf{E}_\lambda \, da \right]^2$$

The second, and not so obvious, step is to divide both sides of this equation by $Y_1(1+R)^2$, using the right side of (8.144) in the denominator on the right. The result is

$$Y_d = \frac{2 \sum_{\lambda=2}^{\infty} Y_\lambda \left[\int_{\text{apertures}} \mathbf{E} \cdot \mathbf{E}_\lambda \, da \right]^2}{Y_1 \left[\int_{\text{apertures}} \mathbf{E} \cdot \mathbf{E}_1 \, da \right]^2} \quad (8.150)$$

where

$$Y_d = \frac{-2R}{1+R} \quad (8.151)$$

is the relative shunt admittance of the diaphragm, in the language of transmission lines.[†] Equation (8.150) can be shown to be stationary with respect to first order variations of the electric field \mathbf{E} away from its true value. It is also homogeneous in \mathbf{E} and so independent of normalization of the trial function. In general the extremum is not a maximum or a minimum. The reason is that the terms in the sum over the cutoff modes do not generally have only one sign. It can be seen from (8.32) that, since $k_\lambda = i\kappa_\lambda$, where κ_λ is real and positive, for the

[†] The reader who is unfamiliar with transmission line theory would do well to establish the connection between reflection and transmission amplitudes and an admittance or impedance across a transmission line. See, for example, Chapters 1 and 11 of *Ramo, Whinnery, and Van Duzer*.

cutoff modes, the phase of the wave admittance depends on the type of mode:

$$Y_\lambda = \begin{cases} -i |Y_\lambda| & \text{(TM)} \\ +i |Y_\lambda| & \text{(TE)} \end{cases}$$

If the incident wave and the geometry of the diaphragm are such that only one type of mode is excited, the sum in (8.150) consists of elements all having the same relative sign and the result for Y_d with a trial function for \mathbf{E} will be a true upper (or lower) bound on the magnitude of the admittance. Otherwise, the result is not a bound, and an improved trial function for \mathbf{E} may yield a smaller or larger magnitude. If the contributions of the *TM modes dominate* in the sum, Y_d will be negative imaginary. The impedance Z_d is thus positive imaginary, and is recognized as *capacitive* when our use of $e^{-i\omega t}$, not $e^{i\omega t}$, is remembered. If the *TE modes dominate*, Y_d is positive imaginary; the diaphragm is an *inductive* obstacle.

For some purposes it is useful to cast (8.150) into a somewhat different form involving a dyadic Green function defined by

$$\vec{\mathbf{G}}(xy | x'y') = 2 \sum_{\lambda=2}^{\infty} Y_\lambda \vec{\mathbf{E}}_\lambda(x, y) \vec{\mathbf{E}}_\lambda(x', y') \quad (8.152)$$

The arrows over the mode fields on the right indicate the permitted directions for vector operations. With this Green function (8.150) can be written

$$Y_d = \frac{\int dx dy \int dx' dy' \mathbf{E}(x, y) \cdot \vec{\mathbf{G}}(xy | x'y') \cdot \mathbf{E}(x', y')}{Y_1 \left[\int dx dy \mathbf{E}(x, y) \cdot \mathbf{E}_1(x, y) \right]^2} \quad (8.153)$$

In certain problems the sum over the modes in (8.152) or an equivalent form can be performed, at least approximately, and the integration in (8.153) is all that need be done, numerically if necessary. Space does not permit extended discussion of the details. The reader may refer to Chapter 8 in Collin and other references cited at the end of the chapter for the working out of specific examples. One or two simple situations are treated in the problems.

In the derivation of the variational principle (8.150) the magnetic field was eliminated from the boundary condition (8.147) in favor of the electric field. An alternative procedure is to eliminate \mathbf{E}_λ in favor of \mathbf{H}_λ in (8.146). Expressions analogous to (8.144) and (8.145) can be written for $(1-R)$ and $A_\lambda^{(-)}$ as integrals over the magnetic fields at $z=0^-$ (from the left side of (8.147)), and for T and $A_\lambda^{(+)}$ as integrals at $z=0^+$. Then a development entirely parallel to the former one leads to a variational expression for the shunt impedance $Z_d = Y_d^{-1}$ of the diaphragm:

$$Z_d = \frac{\frac{1}{2} \sum_{\lambda=2}^{\infty} Z_\lambda \left[\int \mathbf{K} \cdot \mathbf{E}_\lambda da \right]^2}{Z_1 \left[\int \mathbf{K} \cdot \mathbf{E}_1 da \right]^2} \quad (8.154)$$

where

$$\mathbf{K} = \frac{c}{4\pi} \mathbf{e}_3 \times [\mathbf{H}(z=0^+) - \mathbf{H}(z=0^-)] \quad (8.155)$$

is the total surface current density on the diaphragm. The integrations in (8.154) are evidently only over the surface of the diaphragm and are thus complementary to those in (8.150). A combination of the variational principles for Y_d and Z_d can put close limits on the exact value of Y_d , although rapid convergence of the sum over λ in one expression may mean slow convergence in the other.

8.13 Impedance of a Flat Strip Parallel to the Electric Field in a Rectangular Wave Guide

As a simple example of the use of the variational methods of the previous section, we consider the reflections caused by a thin flat perfectly conducting transverse strip shown in Fig. 8.15. The strip is of width d and is oriented in the x - y plane parallel to the electric field of the propagating $TE_{1,0}$ mode with its center at $x = x_0$. The geometry is such that only $TE_{m,0}$ modes are excited. The mode fields are therefore given by (8.130) with $n = 0$; only E_y , H_z and H_x are nonvanishing. The calculation is done in terms of the impedance expression (8.154). Taking advantage of the homogeneous character of (8.154) to clear the numerator and denominator of unnecessary factors, we obtain

$$Z_d = -\frac{ia}{\lambda_g} \sum_{m=2}^{\infty} \left(m^2 - \frac{\omega^2}{\omega_1^2} \right)^{-1/2} \left[\frac{\int dx K(x) \sin \left(\frac{m\pi x}{a} \right)}{\int dx K(x) \sin \left(\frac{\pi x}{a} \right)} \right]^2 \quad (8.156)$$

where $\lambda_g = 2\pi/k_1$ is the wavelength in the guide at frequency ω , $\omega_1 = \pi c/a$ is the cutoff frequency of the $TE_{1,0}$ mode, and $K(x)$ is the surface current (in the y direction) on the strip. The factor $-i$ indicates, with our conventions, that the

Fig. 8.15 Flat inductive strip parallel to the electric field in a rectangular wave guide.

strip acts as an *inductive shunt impedance*. [Electrical engineers should substitute $-j$ for i in all formulas.]

Any relatively reasonable form for the surface current $K(x)$ will yield an approximation for Z_d that is generally accurate to 10 or 20 per cent. With a moderate amount of care considerably better results can be obtained. The simplest assumption is that $K(x)$ is constant over the strip. This calculation is left to the problems at the end of the chapter. A much better approximation is obtained if some recognition is taken of the behavior of $K(x)$ at the edge of the strip. It was shown in Section 2.11 that the fields at the edge of a thin sheet are singular as $(x)^{-1/2}$, where x is the distance from the edge. If this behavior is incorporated into the trial form for $K(x)$, it can be anticipated that the approximation for Z_d will improve. For simplicity we consider $x_0 = a/2$. For such a centered strip $K(x)$ is symmetric about the midpoint and only $m = 1, 3, 5, \dots$ enter (8.156). The typical integral in (8.156) is then

$$I_m = 2 \sin \left(\frac{m\pi}{2} \right) \int_0^{d/2} K(x') \cos \left(\frac{m\pi x'}{a} \right) dx' \quad (8.157)$$

where $x' = x - a/2$. To incorporate the proper behavior at the edges of the strip, we write

$$K(x') = \frac{\bar{K}(x')}{\sqrt{\frac{d^2}{4} - x'^2}} \quad (8.158)$$

where \bar{K} is finite at $x' = \pm d/2$ and is an even function of x' . With a change of variable, $x' = (d/2) \cos \theta$, (8.157) becomes

$$I_m = 2 \sin \left(\frac{m\pi}{2} \right) \int_0^{\pi/2} \bar{K}(\theta) \cos \left(\frac{m\pi d}{2a} \cos \theta \right) d\theta$$

The simplest approximation is $\bar{K} = 1$. Then the integral is, apart from a constant, Poisson's formula for the zeroth order Bessel function. Thus

$$I_m = \pi \sin \left(\frac{m\pi}{2} \right) J_0 \left(\frac{m\pi d}{2a} \right) \quad (8.159)$$

An N -parameter variational trial function for $\bar{K}(\theta)$ is afforded by a finite polynomial expansion in powers of $\sin^2 \theta$ [equivalent to an expansion in powers of $(d^2/4 - x^2)$]:

$$\bar{K}(\theta) = \sum_{k=0}^N b_k (\sin^2 \theta)^k \quad (8.160)$$

with $b_0 = 1$. For this trial function I_m is given by

$$I_m = \pi \sin \left(\frac{m\pi}{2} \right) \sum_{k=0}^N (2k-1)!! b_k \left(\frac{2a}{m\pi d} \right)^k J_k \left(\frac{m\pi d}{2a} \right) \quad (8.161)$$

This expression can be inserted in (8.156) and the result minimized with respect to variations of the coefficients b_k . Here we consider only the simple expression (8.159) based on the first term in (8.160). The impedance of the discontinuity is then approximated by

$$Z_d \approx -\frac{ia}{\lambda_g} \frac{1}{J_0^2\left(\frac{\pi d}{2a}\right)} \sum_{m=3,5,\dots}^{\infty} \frac{J_0^2\left(\frac{m\pi d}{2a}\right)}{\sqrt{m^2 - \frac{\omega^2}{\omega_1^2}}} \quad (8.162)$$

From the asymptotic form (3.91) for the Bessel function it can be seen that the m th term in the series goes as m^{-2} for large m , and so the series converges fairly rapidly, except for very small d/a . Numerical evaluation of (8.162) for a typical value, $d/a=0.25$, yields $(i\lambda_g Z_d/a)=0.259$ for $\omega/\omega_1=1$ and 0.306 for $\omega/\omega_1=2$. For comparison, the corresponding values from Fig. 5.2.8 of *Marcuvitz* are 0.254 and 0.288, respectively. The trial function (8.158) with $\bar{K}=1$ thus overestimates the impedance by only 2 per cent at cutoff and 6 per cent at $\omega/\omega_1=2$. In contrast, the assumption of constant K (Problem 8.12) gives values 15 and 24 per cent too large at $d/a=0.25$. Use of the series (8.160) in a truly variational calculation can improve the estimates still further.

For small values of d/a the series in (8.156) converges slowly. It is advantageous to sum the series before integration and so obtain an expression like (8.153) involving a Green function. The series cannot be summed in closed form for arbitrary ω , but the impedance can be written as two terms, the static value ($\omega=0$) plus a very rapidly convergent series as a correction term:

$$Z_d = Z_d^{(0)} + \Delta Z_d \quad (8.163)$$

where

$$\frac{i\lambda_g}{a} Z_d^{(0)} = \frac{\int dx \int dx' K(x) G(x, x') K(x')}{\left[\int dx K(x) \sin\left(\frac{\pi x}{a}\right) \right]^2} - 1 \quad (8.164)$$

and

$$\frac{i\lambda_g}{a} \Delta Z_d = \sum_{m=2}^{\infty} \left[\frac{1}{\sqrt{m^2 - \frac{\omega^2}{\omega_1^2}}} - \frac{1}{m} \right] \left[\frac{\int dx K(x) \sin\left(\frac{m\pi x}{a}\right)}{\int dx K(x) \sin\left(\frac{\pi x}{a}\right)} \right]^2 \quad (8.165)$$

The coefficient in (8.165) approaches $\omega^2/2\omega_1^2 m^3$ for large m and so gives a very rapidly convergent series in which typically only three or four terms need be kept. The Green function in the static impedance (8.164) is

$$G(x, x') = \sum_{m=1}^{\infty} \frac{1}{m} \sin\left(\frac{m\pi x}{a}\right) \sin\left(\frac{m\pi x'}{a}\right) \quad (8.166)$$

The series can be summed in closed form† to yield

$$G(x, x') = \frac{1}{2} \ln \left| \frac{\sin \frac{\pi}{2a} (x + x')}{\sin \frac{\pi}{2a} (x - x')} \right| \quad (8.167)$$

To lowest order in d/a the numerator in the logarithm can be treated as constant, with $x = x' = x_0$. The static impedance (8.164) is thus approximately

$$\begin{aligned} \frac{i\lambda_g}{a} Z_d^{(0)} \approx & \frac{1}{2} \operatorname{cosec}^2 \left(\frac{\pi x_0}{a} \right) \ln \left(\frac{2a}{\pi d} \sin \frac{\pi x_0}{a} \right) - 1 \\ & + \operatorname{cosec}^2 \left(\frac{\pi x_0}{a} \right) \frac{\int dx \int dx' K(x) K(x') \ln \left| \frac{d}{x - x'} \right|}{2 \left[\int K(x) dx \right]^2} \end{aligned} \quad (8.168)$$

with corrections of order d^2/a^2 . The leading logarithmic behavior is independent of the form of $K(x)$. Only the small correction terms that contribute a constant depend on $K(x)$. With $K = 1$ the coefficient of $\operatorname{cosec}^2 (\pi x_0/a)$ in the last term in (8.168) is equal to $\frac{3}{4}$, while for the form (8.158) with $\bar{K} = 1$ it is $\ln 2 = 0.693$. With this latter value the static impedance is

$$Z_d^{(0)} \approx -\frac{ia}{2\lambda_g} \left[\operatorname{cosec}^2 \left(\frac{\pi x_0}{a} \right) \ln \left(\frac{8a}{\pi d} \sin \frac{\pi x_0}{a} \right) - 2 \right] \quad (8.169)$$

To the same accuracy in powers of d/a , the correction term (8.165) for finite frequencies is

$$\Delta Z_d \approx -\frac{ia}{\lambda_g} \operatorname{cosec}^2 \left(\frac{\pi x_0}{a} \right) \sum_{m=2}^{\infty} \left[\frac{1}{\sqrt{m^2 - \frac{\omega^2}{\omega_1^2}}} - \frac{1}{m} \right] \sin^2 \left(\frac{m\pi x_0}{a} \right) \quad (8.170)$$

Equations (8.169) and (8.170) are the expressions quoted by Marcuvitz, p. 264. The added contribution of ΔZ_d is small. For the centered strip ($x_0 = a/2$), for example, the summation in (8.170) is estimated to be $0.026\omega^2/\omega_1^2$. These last results are reasonably accurate for $d/a \leq 0.1$.

The two approaches described above, the direct series expansion represented by (8.162) and the use of the Green function in closed form, (8.167), illustrate some of the techniques employed in calculating the reflection coefficients for obstacles in wave guides. Many clever and ingenious methods are discussed in the specialized literature, to which the interested reader may refer.

† Appendix A.6 of Collin discusses several methods of summing series like (8.166). The example in our own Section 2.10 can be adapted to yield (8.167).

REFERENCES AND SUGGESTED READING

Wave guides and resonant cavities are discussed in numerous electrical and communications engineering books, for example,

Ramo, Whinnery, and Van Duzer, Chapters 7, 8, 10, and 11.

The two books by Schelkunoff deserve mention for their clarity and physical insight, Schelkunoff, *Electromagnetic Fields*,

Schelkunoff, *Applied Mathematics for Engineers and Scientists*.

Among the physics textbooks that treat wave guides, transmission lines, and cavities are Panofsky and Phillips, Chapter 12,

Slater,

Smythe, Chapter XIII,

Sommerfeld, *Electrodynamics*, Sections 22–25,

Stratton, Sections 9.18–9.22.

An authoritative discussion appears in

F. E. Borgnis and C. H. Papas, *Electromagnetic Waveguides and Resonators*, Vol. XVI of the *Encyclopaedia of Physics*, ed. S. Flugge, Springer-Verlag, Berlin, 1958.

The books by

Collin,

Harrington,

Johnson,

Waldron,

are intended for graduate engineers and physicists and are devoted almost completely to guided waves and cavities. The standard theory, plus many specialized topics like discontinuities, are covered in detail. The original work on variational methods for discontinuities is summarized in

J. Schwinger and D. S. Saxon, *Discontinuities in Waveguides, Notes on Lectures by Julian Schwinger*, Gordon and Breach, New York, 1968.

Variational principles for eigenfrequencies, etc., as well as discontinuities, are surveyed in

L. Cairo and T. Kahan,

and also discussed by

Harrington, Chapter 7,

Van Bladel, Chapter 13,

Waldron, Chapter 8.

The definitive compendium of formulas and numerical results on discontinuities, junctions, etc. in wave guides is

Marcuvitz.

The mathematical tools for the treatment of these boundary-value problems are presented by

Morse and Feshbach, especially Chapter 13.

Perturbation of boundary conditions is discussed by Morse and Feshbach, pp. 1038 ff.

Information on special functions may be found in the ever-reliable

Magnus and Oberhettinger in the original, and also the revision with Soni, and in encyclopaedic detail in

Bateman Manuscript Project, *Higher Transcendental Functions*.

Numerical values of special functions, as well as formulas, are given by

Abramowitz and Stegun,

Jahnke, Emde and Lösch.

Two books dealing with propagation of electromagnetic waves around the earth and in

the ionosphere from the point of view of wave guides and normal modes are

K. G. Budden, *The Wave-guide Mode Theory of Wave Propagation*, Logos Press and Academic Press, London, 1961.

PROBLEMS

- 8.1** A transmission line consisting of two concentric circular cylinders of metal with conductivity σ and skin depth δ , as shown below, is filled with a uniform lossless dielectric (μ, ϵ). A TEM mode is propagated along this line.

(a) Show that the time-averaged power flow along the line is

$$P = \left[\frac{c}{4\pi} \right] \sqrt{\frac{\mu}{\epsilon}} \pi a^2 |H_0|^2 \ln \left(\frac{b}{a} \right) \quad (1)^*$$

where H_0 is the peak value of the azimuthal magnetic field at the surface of the inner conductor.

Problem 8.1

- (b) Show that the transmitted power is attenuated along the line as

$$P(z) = P_0 e^{-2\gamma z}$$

where

$$\gamma = \left[\frac{c}{4\pi} \right] \frac{1}{2\sigma\delta} \sqrt{\frac{\epsilon}{\mu}} \left(\frac{1}{a} + \frac{1}{b} \right) \ln \left(\frac{b}{a} \right) \quad (2)^*$$

- (c) The characteristic impedance Z_0 of the line is defined as the ratio of the voltage between the cylinders to the axial current flowing in one of them at any position z . Show that for this line

$$Z_0 = \left[\frac{4\pi}{c} \right] \frac{1}{2\pi} \sqrt{\frac{\mu}{\epsilon}} \ln \left(\frac{b}{a} \right) \quad (3)^*$$

(d) Show that the series resistance and inductance per unit length of the line are

$$R = \frac{1}{2\pi\sigma\delta} \left(\frac{1}{a} + \frac{1}{b} \right) \quad (4)^*$$

$$L = \left[\frac{4\pi}{c^2} \right] \left\{ \frac{\mu}{2\pi} \ln \left(\frac{b}{a} \right) + \frac{\mu_c \delta}{4\pi} \left(\frac{1}{a} + \frac{1}{b} \right) \right\} \quad (5)^*$$

where μ_c is the permeability of the conductor. The correction to the inductance comes from the penetration of the flux into the conductors by a distance of order δ .

8.2 A transmission line consists of two identical thin strips of metal, shown in cross section below. Assuming that $b \gg a$, discuss the propagation of a TEM mode on this line, repeating the derivations of Problem 8.1. Show that

$$P = \left[\frac{c}{4\pi} \right] \frac{ab}{2} \sqrt{\frac{\mu}{\epsilon}} |H_0|^2 \quad (1)^*$$

$$\gamma = \left[\frac{c}{4\pi} \right] \frac{1}{a\sigma\delta} \sqrt{\frac{\epsilon}{\mu}} \quad (2)^*$$

$$Z_0 = \left[\frac{4\pi}{c} \right] \sqrt{\frac{\mu}{\epsilon}} \left(\frac{a}{b} \right) \quad (3)^*$$

$$R = \frac{2}{\sigma\delta b} \quad (4)^*$$

$$L = \left[\frac{4\pi}{c^2} \right] \left(\frac{\mu a + \mu_c \delta}{b} \right) \quad (5)^*$$

Problem 8.2

where the symbols have the same meanings as in Problem 8.1.

8.3 Transverse electric and magnetic waves are propagated along a hollow, right circular cylinder of brass with inner radius R .

(a) Find the cutoff frequencies of the various TE and TM modes. Determine numerically the lowest cutoff frequency (the dominant mode) in terms of the tube radius and the ratio of cutoff frequencies of the next four higher modes to that of the dominant mode. For this part assume that the conductivity of brass is infinite.

(b) Calculate the attenuation constant of the wave guide as a function of frequency for the lowest two modes and plot it as a function of frequency.

- 8.4** A wave guide is constructed so that the cross section of the guide forms a right triangle with sides of length a , a , $\sqrt{2}a$, as shown below. The medium inside has $\mu = \epsilon = 1$.

(a) Assuming infinite conductivity for the walls, determine the possible modes of propagation and their cutoff frequencies.

Problem 8.4

(b) For the lowest modes of each type calculate the attenuation constant, assuming that the walls have large, but finite, conductivity. Compare the result with that for a square guide of side a made from the same material.

- 8.5** A resonant cavity of copper consists of a hollow, right circular cylinder of inner radius R and length L , with flat end faces.

(a) Determine the resonant frequencies of the cavity for all types of waves. With $(c/\sqrt{\mu\epsilon}R)$ as a unit of frequency, plot the lowest four resonant frequencies of each type as a function of R/L for $0 < R/L < 2$. Does the same mode have the lowest frequency for all R/L ?

(b) If $R = 2$ cm, $L = 3$ cm, and the cavity is made of pure copper, what is the numerical value of Q for the lowest resonant mode?

- 8.6** A resonant cavity consists of the empty space between two perfectly conducting, concentric spherical shells, the smaller having an outer radius a and the larger an inner radius b . As shown in Section 8.9, the azimuthal magnetic field has a radial dependence given by spherical Bessel functions, $j_l(kr)$ and $n_l(kr)$, where $k = \omega/c$.

(a) Write down the transcendental equation for the characteristic frequencies of the cavity for arbitrary l .

(b) For $l = 1$ use the explicit forms of the spherical Bessel functions to show that the characteristic frequencies are given by

$$\frac{\tan kh}{kh} = \frac{\left(k^2 + \frac{1}{ab}\right)}{k^2 + ab\left(k^2 - \frac{1}{a^2}\right)\left(k^2 - \frac{1}{b^2}\right)}$$

where $h = b - a$.

(c) For $h/a \ll 1$, verify that the result of (b) yields the frequency found in Section 8.9, and find the first order correction in h/a .

[The result of part (b) seems to have been derived first by J. J. Thomson and published in his book, *Recent Researches in Electricity and Magnetism*, Oxford Clarendon Press, 1893, pp. 373 ff.]

- 8.7 For the Schumann resonances of Section 8.9 calculate the Q values on the assumption that the earth has a conductivity σ_e and the ionosphere has a conductivity σ_i , with corresponding skin depths δ_e and δ_i .
- (a) Show that to lowest order in h/a the Q value is given by $Q = Nh/(\delta_e + \delta_i)$ and determine the numerical factor N for all l .
- (b) For the lowest Schumann resonance evaluate the Q value assuming $\sigma_e = 10^9 \text{ sec}^{-1}$, $\sigma_i = 10^5 \text{ sec}^{-1}$, $h = 10^2 \text{ km}$.
- (c) Discuss the validity of the approximations used in (a) for the range of parameters used in (b).
- 8.8 A right circular cylinder of nonpermeable dielectric with dielectric constant ϵ and radius a serves as a dielectric wave guide in vacuum.
- (a) Discuss the propagation of waves along such a guide, assuming that the azimuthal variation of the fields is $e^{im\phi}$.
- (b) For $m = \pm 1$, determine the mode with the lowest cutoff frequency and discuss the properties of its fields (cutoff frequency, spatial variation, etc.), assuming that $\epsilon \gg 1$.
- 8.9 (a) From the use of Green's theorem in two dimensions show that the TM and TE modes in a wave guide defined by the boundary-value problems (8.34) and (8.36) are orthogonal in the sense that

$$\int_A E_{z\lambda} E_{z\mu} da = 0 \quad \text{for } \lambda \neq \mu$$

for TM modes, and a corresponding relation for H_z for TE modes.

(b) Prove that the relations (8.125)–(8.128) form a consistent set of normalization conditions for the fields, including the circumstance when λ is a TM mode and μ is a TE mode.

- 8.10 An infinitely long rectangular wave guide has the center conductor of a coaxial line extending vertically a distance h into its interior at $z=0$, as shown in the cross-sectional view. The current along the probe oscillates sinusoidally in time with frequency ω , and its variation in space can be approximated as $I(y) = I_0 \sin[(\omega/c)(h-y)]$. The thickness of the probe can be neglected. The frequency is such that only the $\text{TE}_{1,0}$ mode can propagate in the guide.

Problem 8.10

- (a) Calculate the amplitudes for excitation of both TE and TM modes for all (m, n) and show how the amplitudes depend on m and n for $m, n \gg 1$ for a fixed frequency ω .
- (b) For the propagating mode show that the power radiated in the positive z direction is

$$P = \frac{4\pi\mu I_0^2}{\omega k ab} \sin^2\left(\frac{\pi X}{a}\right) \sin^4\left(\frac{\omega h}{2c}\right)$$

with an equal amount in the opposite direction. Here k is the wave number for the $TE_{1,0}$ mode.

(c) Discuss the modifications that occur if the guide, instead of running off to infinity in both directions, is terminated with a perfectly conducting surface at $z=L$. What values of L will maximize the power flow for a fixed current I_0 ? What is the radiation resistance of the probe (defined as the ratio of power flow to one-half the square of the current at the base of the probe) at maximum?

- 8.11** An infinitely long rectangular wave guide has a coaxial line terminating in the short side of the guide with the thin central conductor forming a semicircular loop of radius R whose center is a height h above the floor of the guide, as shown in the accompanying cross-sectional view. The half-loop is in the plane $z=0$ and its radius R is sufficiently small that the current can be taken as having a constant value I_0 everywhere on the loop.

Problem 8.11

(a) Prove that, to the extent that the current is constant around the half-loop the TM modes are not excited. Give a physical explanation of this lack of excitation.

(b) Determine the amplitude for the lowest TE mode in the guide and show that its value is independent of the height h .

(c) Show that the power radiated in either direction in the lowest TE mode is

$$P = \frac{\pi I_0^2}{4c} Z \frac{a}{b} \left(\frac{\pi R}{a} \right)^4$$

where Z is the wave impedance of the $TE_{1,0}$ mode. Here assume $R \ll a, b$.

- 8.12** Discuss the reflection by a flat strip of width d , centered at $x=x_0$, in a rectangular guide, as shown in Fig. 8.15.

(a) Use the approximation of $K(x)=1$ in (8.156) to show that the shunt impedance is approximated by

$$Z_d = -\frac{ia}{\lambda_g} \sum_{m=2}^{\infty} \frac{1}{m^2 \sqrt{m^2 - \frac{\omega^2}{\omega_1^2}}} \left[\frac{\sin\left(\frac{m\pi x_0}{a}\right) \sin\left(\frac{m\pi d}{2a}\right)}{\sin\left(\frac{\pi x_0}{a}\right) \sin\left(\frac{\pi d}{2a}\right)} \right]^2$$

(b) For a centered strip ($x_0 = a/2$) evaluate the sum in (a) numerically for $d/a = 0.3$ and $\omega/\omega_1 = 1.0$, and compare with the accurate result (read from Fig. 5.2.8 of Marcuvitz), $i\lambda_g Z_d/a = 0.186$.

- 8.13** Consider reflection of the $TE_{1,0}$ mode in a rectangular wave guide with an aperture that is the complement of the strip shown in Fig. 8.15, as indicated in the sketch below.

**Problem 8.13**

(a) Show that the shunt admittance can be written

$$Y_d = \frac{i\lambda_g}{a} \sum_{m=2}^{\infty} \frac{\sqrt{m^2 - \frac{\omega^2}{\omega_1^2}}}{m^2} \left[\frac{\int dx H_z(x) \cos\left(\frac{m\pi x}{a}\right)}{\int dx H_z(x) \cos\left(\frac{\pi x}{a}\right)} \right]^2$$

where $H_z(x)$ is the longitudinal magnetic field in the aperture.

(b) Show that the static Green function defined in analogy with (8.166) is

$$G(x, x') = -\frac{1}{2} \ln \left[2 \left| \cos\left(\frac{\pi x}{a}\right) - \cos\left(\frac{\pi x'}{a}\right) \right| \right]$$

(c) Show that, if $H_z(x)$ is approximated by the *lowest order* polynomial in x consistent with the symmetry of the fields, a *narrow, centered aperture* has a static admittance,

$$Y_d^{(0)} \approx \frac{i\lambda_g}{a} \left[\frac{9}{2\pi^2} \left(\frac{a}{d}\right)^2 \right]$$

with corrections of order $(d/a)^2$ relative to the leading term. The correct answer in the limit of $d/a \ll 1$ is 8/9 times this value.

9

Simple Radiating Systems, Scattering, and Diffraction

In Chapters 7 and 8 we have discussed the properties of electromagnetic waves and their propagation in both bounded and unbounded geometries. But very little has been said about the generation of such waves. In the present chapter we turn to this question and discuss the emission of radiation by localized oscillating systems of charge and current density. The treatment is straightforward, without elaborate formalism. By its nature it is restricted to rather simple radiating systems. The systematic approach, with vector multipole fields for arbitrary l , is deferred to Chapter 16. Here we discuss only the electric and magnetic dipoles and the electric quadrupole, as well as some simple configurations of currents on conductors. The simple multipole expansion for a source in a wave guide is also treated, and the effective multipole moments of apertures.

The second, larger part of the chapter concerns scattering and diffraction. First scattering at long wavelengths, including Rayleigh's explanation of the blue sky and related topics, are explained. Then scalar and vector diffraction theory are discussed, with some examples. Scattering at short wavelengths and the important *optical theorem* end the chapter.

9.1 Fields and Radiation of a Localized Oscillating Source

For a system of charges and currents varying in time we can make a Fourier analysis of the time dependence and handle each Fourier component separately. We therefore lose no generality by considering the potentials, fields, and radiation from a localized system of charges and currents which vary sinusoidally in time:

$$\left. \begin{aligned} \rho(\mathbf{x}, t) &= \rho(\mathbf{x}) e^{-i\omega t} \\ \mathbf{J}(\mathbf{x}, t) &= \mathbf{J}(\mathbf{x}) e^{-i\omega t} \end{aligned} \right\} \quad (9.1)$$

As usual, the real part of such expressions is to be taken to obtain physical quantities.* The electromagnetic potentials and fields are assumed to have the same time dependence.

It was shown in Chapter 6 that the solution for the vector potential $\mathbf{A}(\mathbf{x}, t)$ in the Lorentz gauge is

$$\mathbf{A}(\mathbf{x}, t) = \frac{1}{c} \int d^3x' \int dt' \frac{\mathbf{J}(\mathbf{x}', t')}{|\mathbf{x} - \mathbf{x}'|} \delta\left(t' + \frac{|\mathbf{x} - \mathbf{x}'|}{c} - t\right) \quad (9.2)$$

provided no boundary surfaces are present. The Dirac delta function assures the causal behavior of the fields. With the sinusoidal time dependence (9.1), the solution for \mathbf{A} becomes

$$\mathbf{A}(\mathbf{x}) = \frac{1}{c} \int \mathbf{J}(\mathbf{x}') \frac{e^{ik|\mathbf{x} - \mathbf{x}'|}}{|\mathbf{x} - \mathbf{x}'|} d^3x' \quad (9.3)$$

where $k = \omega/c$ is the wave number, and a sinusoidal time dependence is understood. The magnetic induction is given by

$$\mathbf{B} = \nabla \times \mathbf{A} \quad (9.4)$$

while, outside the source, the electric field is

$$\mathbf{E} = \frac{i}{k} \nabla \times \mathbf{B} \quad (9.5)$$

Given a current distribution $\mathbf{J}(\mathbf{x}')$, the fields can, in principle at least, be determined by calculating the integral in (9.3). We will consider one or two examples of direct integration of the source integral in Section 9.4. But at present we wish to establish certain simple, but general, properties of the fields in the limit that the source of current is confined to a small region, very small in fact compared to a wavelength. If the source dimensions are of order d and the wavelength is $\lambda = 2\pi c/\omega$, and if $d \ll \lambda$, then there are three spatial regions of interest:

The near (static) zone: $d \ll r \ll \lambda$

The intermediate (induction) zone: $d \ll r \sim \lambda$

The far (radiation) zone: $d \ll \lambda \ll r$

We will see that the fields have very different properties in the different zones. In the near zone the fields have the character of static fields with radial components and variation with distance which depends in detail on the properties of the source. In the far zone, on the other hand, the fields are transverse to the radius vector and fall off as r^{-1} , typical of radiation fields.

* See Problem 9.1 for some of the subtleties that can arise over factors of 2. There are also factors of 2 in the correspondence between classical and quantum-mechanical quantities. For example, in a one-electron atom our classical dipole moment \mathbf{p} is replaced by $2e\langle f | \mathbf{r} | i \rangle$ for a transition from state i to state f .

For the near zone where $r \ll \lambda$ (or $kr \ll 1$) the exponential in (9.3) can be replaced by unity. Then the vector potential is of the form already considered in Chapter 5. The inverse distance can be expanded using (3.70), with the result,

$$\lim_{kr \rightarrow 0} \mathbf{A}(\mathbf{x}) = \frac{1}{c} \sum_{l,m} \frac{4\pi}{2l+1} \frac{Y_{lm}(\theta, \phi)}{r^{l+1}} \int \mathbf{J}(\mathbf{x}') r'^l Y_{lm}^*(\theta', \phi') d^3 x' \quad (9.6)$$

This shows that the near fields are quasi-stationary, oscillating harmonically as $e^{-i\omega t}$, but otherwise static in character.

In the far zone ($kr \gg 1$) the exponential in (9.3) oscillates rapidly and determines the behavior of the vector potential. In this region it is sufficient to approximate*

$$|\mathbf{x} - \mathbf{x}'| \approx r - \mathbf{n} \cdot \mathbf{x}' \quad (9.7)$$

where \mathbf{n} is a unit vector in the direction of \mathbf{x} . Furthermore, if only the leading term in kr is desired, the inverse distance in (9.3) can be replaced by r . Then the vector potential is

$$\lim_{kr \rightarrow \infty} \mathbf{A}(\mathbf{x}) = \frac{e^{ikr}}{cr} \int \mathbf{J}(\mathbf{x}') e^{-ik\mathbf{n} \cdot \mathbf{x}'} d^3 x' \quad (9.8)$$

This demonstrates that in the far zone the vector potential behaves as an outgoing spherical wave with an angular dependent coefficient. It is easy to show that the fields calculated from (9.4) and (9.5) are transverse to the radius vector and fall off as r^{-1} . They thus correspond to radiation fields. If the source dimensions are small compared to a wavelength it is appropriate to expand the integral in (9.8) in powers of k :

$$\lim_{kr \rightarrow \infty} \mathbf{A}(\mathbf{x}) = \frac{e^{ikr}}{cr} \sum_n \frac{(-ik)^n}{n!} \int \mathbf{J}(\mathbf{x}') (\mathbf{n} \cdot \mathbf{x}')^n d^3 x' \quad (9.9)$$

The magnitude of the n th term is given by

$$\frac{1}{n!} \int \mathbf{J}(\mathbf{x}') (k\mathbf{n} \cdot \mathbf{x}')^n d^3 x' \quad (9.10)$$

Since the order of magnitude of \mathbf{x}' is d and kd is small compared to unity by assumption, the successive terms in the expansion of \mathbf{A} evidently fall off rapidly with n . Consequently the radiation emitted from the source will come mainly from the first nonvanishing term in the expansion (9.9). We will examine the first few of these in the following sections.

In the intermediate or induction zone the two alternative approximations leading to (9.6) and (9.8) cannot be made; all powers of kr must be retained.

* Actually (9.7) is valid for $r \gg d$, independent of the value of kr . It is therefore an adequate approximation even in the near zone.

Without marshalling the full apparatus of vector multipole fields, described in Chapter 16, we can abstract enough for our immediate purpose. The key result is the exact expansion (16.22) for the Green function appearing in (9.3). For points outside the source (9.3) then becomes

$$\mathbf{A}(\mathbf{x}) = \frac{4\pi ik}{c} \sum_{l,m} h_l^{(1)}(kr) Y_{lm}(\theta, \phi) \int \mathbf{J}(\mathbf{x}') j_l(kr') Y_{lm}^*(\theta', \phi') d^3x' \quad (9.11)$$

If the source dimensions are small compared to a wavelength, $j_l(kr')$ can be approximated by (16.12). Then the result for the vector potential is of the form of (9.6), but with the replacement,

$$\frac{1}{r^{l+1}} \rightarrow \frac{e^{ikr}}{r^{l+1}} (1 + a_1(ikr) + a_2(ikr)^2 + \cdots + a_l(ikr)^l) \quad (9.12)$$

The numerical coefficients a_l come from the explicit expressions for the spherical Hankel functions. The right hand side of (9.12) shows the transition from the static-zone result (9.6) for $kr \ll 1$ to the radiation-zone form (9.9) for $kr \gg 1$.

Before discussing electric dipole and other types of radiation we examine the question of electric monopole fields when the sources vary in time. The analogue of (9.2) for the scalar potential is

$$\Phi(\mathbf{x}, t) = \int d^3x' \int dt' \frac{\rho(\mathbf{x}', t')}{|\mathbf{x} - \mathbf{x}'|} \delta\left(t' + \frac{|\mathbf{x} - \mathbf{x}'|}{c} - t\right)$$

The electric monopole contribution is obtained by replacing $|\mathbf{x} - \mathbf{x}'| \rightarrow |\mathbf{x}| \equiv r$ under the integral. The result is

$$\Phi_{\text{monopole}}(\mathbf{x}, t) = \frac{q(t' = t - r/c)}{r}$$

where $q(t)$ is the total charge of the source. Since charge is conserved and a localized source is by definition one that does not have charge flowing into or away from it, the total charge q is independent of time. Thus the *electric monopole part* of the potential (and fields) of a localized source is of necessity *static*. The fields with harmonic time dependence $e^{-i\omega t}$, $\omega \neq 0$, have no monopole terms.

We now turn to the lowest order multipole fields for $\omega \neq 0$. Because these fields can be calculated from the vector potential alone via (9.4) and (9.5), we omit explicit reference to the scalar potential in what follows.

9.2 Electric Dipole Fields and Radiation

If only the first term in (9.9) is kept, the vector potential is

$$\mathbf{A}(\mathbf{x}) = \frac{e^{ikr}}{cr} \int \mathbf{J}(\mathbf{x}') d^3x' \quad (9.13)$$

Examination of (9.11) and (9.12) shows that (9.13) is the $l=0$ part of the series and that it is valid everywhere outside the source, not just in the far zone. The integral can be put in more familiar terms by an integration by parts:

$$\int \mathbf{J} d^3x' = - \int \mathbf{x}' (\nabla' \cdot \mathbf{J}) d^3x' = -i\omega \int \mathbf{x}' \rho(\mathbf{x}') d^3x' \quad (9.14)$$

since from the continuity equation,

$$i\omega\rho = \nabla \cdot \mathbf{J} \quad (9.15)$$

Thus the vector potential is

$$\mathbf{A}(\mathbf{x}) = -ik\mathbf{p} \frac{e^{ikr}}{r} \quad (9.16)$$

where

$$\mathbf{p} = \int \mathbf{x}' \rho(\mathbf{x}') d^3x' \quad (9.17)$$

is the *electric dipole moment*, as defined in electrostatics by (4.8).

The electric dipole fields from (9.4) and (9.5) are

$$\left. \begin{aligned} \mathbf{B} &= k^2(\mathbf{n} \times \mathbf{p}) \frac{e^{ikr}}{r} \left(1 - \frac{1}{ikr}\right) \\ \mathbf{E} &= k^2(\mathbf{n} \times \mathbf{p}) \times \mathbf{n} \frac{e^{ikr}}{r} + [3\mathbf{n}(\mathbf{n} \cdot \mathbf{p}) - \mathbf{p}] \left(\frac{1}{r^3} - \frac{ik}{r^2}\right) e^{ikr} \end{aligned} \right\} \quad (9.18)$$

We note that the magnetic induction is transverse to the radius vector at all distances, but that the electric field has components parallel and perpendicular to \mathbf{n} .

In the radiation zone the fields take on the limiting forms,

$$\left. \begin{aligned} \mathbf{B} &= k^2(\mathbf{n} \times \mathbf{p}) \frac{e^{ikr}}{r} \\ \mathbf{E} &= \mathbf{B} \times \mathbf{n} \end{aligned} \right\} \quad (9.19)$$

showing the typical behavior of radiation fields.

In the near zone, on the other hand, the fields approach

$$\left. \begin{aligned} \mathbf{B} &= ik(\mathbf{n} \times \mathbf{p}) \frac{1}{r^2} \\ \mathbf{E} &= [3\mathbf{n}(\mathbf{n} \cdot \mathbf{p}) - \mathbf{p}] \frac{1}{r^3} \end{aligned} \right\} \quad (9.20)$$

The electric field, apart from its oscillations in time, is just the static electric dipole field (4.13). The magnetic induction is a factor (kr) smaller than the electric field in the region where $kr \ll 1$. Thus the fields in the near zone are dominantly electric in nature. The magnetic induction vanishes, of course, in the static limit $k \rightarrow 0$. Then the near zone extends to infinity.

The time-averaged power radiated per unit solid angle by the oscillating

dipole moment \mathbf{p} is

$$\frac{dP}{d\Omega} = \frac{c}{8\pi} \operatorname{Re} [r^2 \mathbf{n} \cdot \mathbf{E} \times \mathbf{B}^*] \quad (9.21)$$

where \mathbf{E} and \mathbf{B} are given by (9.19). Thus we find

$$\frac{dP}{d\Omega} = \frac{c}{8\pi} k^4 |(\mathbf{n} \times \mathbf{p}) \times \mathbf{n}|^2 \quad (9.22)$$

The state of polarization of the radiation is given by the vector inside the absolute value signs (See the footnote on p. 659). If the components of \mathbf{p} all have the same phase, the angular distribution is a typical dipole pattern,

$$\frac{dP}{d\Omega} = \frac{c}{8\pi} k^4 |\mathbf{p}|^2 \sin^2 \theta \quad (9.23)$$

where the angle θ is measured from the direction of \mathbf{p} . The total power radiated, independent of the relative phases of the components of \mathbf{p} , is

$$P = \frac{ck^4}{3} |\mathbf{p}|^2 \quad (9.24)$$

A simple example of an electric dipole radiator is a centered, linear antenna whose length d is small compared to a wavelength. The antenna is assumed to be oriented along the z axis, extending from $z = (d/2)$ to $z = -(d/2)$ with a narrow gap at the center for purposes of excitation, as shown in Fig. 9.1. The current is in the same direction in each half of the antenna, having a value I_0 at the gap and falling approximately linearly to zero at the ends:

$$I(z)e^{-i\omega t} = I_0 \left(1 - \frac{2|z|}{d}\right) e^{-i\omega t} \quad (9.25)$$

From the continuity equation (9.15) the linear-charge density ρ' (charge per unit

Fig. 9.1 Short, center-fed, linear antenna.

length) is constant along each arm of the antenna, with the value,

$$\rho'(z) = \pm \frac{2iI_0}{\omega d} \quad (9.26)$$

the upper (lower) sign being appropriate for positive (negative) values of z . The dipole moment (9.17) is parallel to the z axis and has the magnitude

$$p = \int_{-(d/2)}^{(d/2)} z \rho'(z) dz = \frac{iI_0 d}{2\omega} \quad (9.27)$$

The angular distribution of radiated power is

$$\frac{dP}{d\Omega} = \frac{I_0^2}{32\pi c} (kd)^2 \sin^2 \theta \quad (9.28)$$

while the total power radiated is

$$P = \frac{I_0^2 (kd)^2}{12c} \quad (9.29)$$

We see that for a fixed input current the power radiated increases as the square of the frequency, at least in the long-wavelength domain where $kd \ll 1$.

The coefficient of $I_0^2/2$ in (9.29) has the dimensions of a resistance and is called the *radiation resistance* R_{rad} of the antenna. It corresponds to the second term in (6.137) and is the total resistance of the antenna if the conductivity is perfect. The value of the radiation resistance in ohms is obtained by multiplying the coefficient of $I_0^2/2$ by $30c$. Thus for this short center-fed antenna $R_{\text{rad}} \approx 5(kd)^2$ ohms. In principle the input reactance for the antenna can be calculated by applying Eq. (6.138) or (6.140) of Section 6.10. Unfortunately the calculation depends crucially on the strong fields near the gap and thus is sensitive to the exact shape and method of excitation. Since the system is an *electric* dipole and the electrostatic dipole field dominates near the antenna, we can nevertheless say with certainty that the reactance is negative (capacitive) for small kd .

9.3 Magnetic Dipole and Electric Quadrupole Fields

The next term in expansion (9.9) leads to a vector potential,

$$\mathbf{A}(\mathbf{x}) = \frac{e^{ikr}}{cr} \left(\frac{1}{r} - ik \right) \int \mathbf{J}(\mathbf{x}') (\mathbf{n} \cdot \mathbf{x}') d^3x' \quad (9.30)$$

where we have included the correct terms from (9.12) in order to make (9.30) valid everywhere outside the source. This vector potential can be written as the sum of two terms, one of which gives a transverse magnetic induction and the other of which gives a transverse electric field. These physically distinct contributions can be separated by writing the integrand in (9.30) as the sum of a

part symmetric in \mathbf{J} and \mathbf{x}' and a part that is antisymmetric. Thus

$$\frac{1}{c} (\mathbf{n} \cdot \mathbf{x}') \mathbf{J} = \frac{1}{2c} [(\mathbf{n} \cdot \mathbf{x}') \mathbf{J} + (\mathbf{n} \cdot \mathbf{J}) \mathbf{x}'] + \frac{1}{2c} (\mathbf{x}' \times \mathbf{J}) \times \mathbf{n} \quad (9.31)$$

The second, antisymmetric part is recognizable as the magnetization due to the current \mathbf{J} :

$$\mathcal{M} = \frac{1}{2c} (\mathbf{x} \times \mathbf{J}) \quad (9.32)$$

The first, symmetric term will be shown to be related to the electric quadrupole moment density.

Considering only the magnetization term, we have the vector potential,

$$\mathbf{A}(\mathbf{x}) = ik(\mathbf{n} \times \mathbf{m}) \frac{e^{ikr}}{r} \left(1 - \frac{1}{ikr}\right) \quad (9.33)$$

where \mathbf{m} is the *magnetic dipole moment*,

$$\mathbf{m} = \int \mathcal{M} d^3x = \frac{1}{2c} \int (\mathbf{x} \times \mathbf{J}) d^3x \quad (9.34)$$

The fields can be determined by noting that the vector potential (9.33) is proportional to the magnetic induction (9.18) for an electric dipole. This means that the magnetic induction for the present magnetic dipole source will be equal to the electric field for the electric dipole, with the substitution $\mathbf{p} \rightarrow \mathbf{m}$. Thus we find

$$\mathbf{B} = k^2(\mathbf{n} \times \mathbf{m}) \times \mathbf{n} \frac{e^{ikr}}{r} + [3\mathbf{n}(\mathbf{n} \cdot \mathbf{m}) - \mathbf{m}] \left(\frac{1}{r^3} - \frac{ik}{r^2}\right) e^{ikr} \quad (9.35)$$

Similarly, the electric field for a magnetic dipole source is the negative of the magnetic field for an electric dipole:

$$\mathbf{E} = -k^2(\mathbf{n} \times \mathbf{m}) \frac{e^{ikr}}{r} \left(1 - \frac{1}{ikr}\right) \quad (9.36)$$

All the arguments concerning the behavior of the fields in the near and far zones are the same as for the electric dipole source, with the interchanges $\mathbf{E} \rightarrow \mathbf{B}$, $\mathbf{B} \rightarrow -\mathbf{E}$, $\mathbf{p} \rightarrow \mathbf{m}$. Similarly the radiation pattern and total power radiated are the same for the two kinds of dipole. The only difference in the radiation fields is in the polarization. For an electric dipole the electric vector lies in the plane defined by \mathbf{n} and \mathbf{p} , while for a magnetic dipole it is perpendicular to the plane defined by \mathbf{n} and \mathbf{m} .

The integral of the symmetric term in (9.31) can be transformed by an integration by parts and some rearrangement:

$$\frac{1}{2c} \int [(\mathbf{n} \cdot \mathbf{x}') \mathbf{J} + (\mathbf{n} \cdot \mathbf{J}) \mathbf{x}'] d^3x' = -\frac{ik}{2} \int \mathbf{x}'(\mathbf{n} \cdot \mathbf{x}') \rho(\mathbf{x}') d^3x' \quad (9.37)$$

The continuity equation (9.15) has been used to replace $\nabla \cdot \mathbf{J}$ by $i\omega\rho$. Since the integral involves second moments of the charge density, this symmetric part corresponds to an electric quadrupole source. The vector potential is

$$\mathbf{A}(\mathbf{x}) = -\frac{k^2}{2} \frac{e^{ikr}}{r} \left(1 - \frac{1}{ikr}\right) \int \mathbf{x}'(\mathbf{n} \cdot \mathbf{x}') \rho(\mathbf{x}') d^3x' \quad (9.38)$$

The complete fields are somewhat complicated to write down. We will content ourselves with the fields in the radiation zone. Then it is easy to see that

$$\left. \begin{aligned} \mathbf{B} &= ik\mathbf{n} \times \mathbf{A} \\ \mathbf{E} &= ik(\mathbf{n} \times \mathbf{A}) \times \mathbf{n} \end{aligned} \right\} \quad (9.39)$$

Consequently the magnetic induction is

$$\mathbf{B} = -\frac{ik^3}{2} \frac{e^{ikr}}{r} \int (\mathbf{n} \times \mathbf{x}')(\mathbf{n} \cdot \mathbf{x}') \rho(\mathbf{x}') d^3x' \quad (9.40)$$

With definition (4.9) for the *quadrupole moment tensor*,

$$Q_{\alpha\beta} = \int (3x_\alpha x_\beta - r^2 \delta_{\alpha\beta}) \rho(\mathbf{x}) d^3x \quad (9.41)$$

the integral in (9.40) can be written

$$\mathbf{n} \times \int \mathbf{x}'(\mathbf{n} \cdot \mathbf{x}') \rho(\mathbf{x}') d^3x' = \frac{1}{3} \mathbf{n} \times \mathbf{Q}(\mathbf{n}) \quad (9.42)$$

The vector $\mathbf{Q}(\mathbf{n})$ is defined as having components,

$$Q_\alpha = \sum_\beta Q_{\alpha\beta} n_\beta \quad (9.43)$$

We note that it depends in magnitude and direction on the direction of observation as well as on the properties of the source. With these definitions we have the magnetic induction,

$$\mathbf{B} = -\frac{ik^3}{6} \frac{e^{ikr}}{r} \mathbf{n} \times \mathbf{Q}(\mathbf{n}) \quad (9.44)$$

and the time-averaged power radiated per unit solid angle,

$$\frac{dP}{d\Omega} = \frac{c}{288\pi} k^6 |[\mathbf{n} \times \mathbf{Q}(\mathbf{n})] \times \mathbf{n}|^2 \quad (9.45)$$

where again the direction of the radiated electric field is given by the vector inside the absolute value signs.

The general angular distribution is complicated. But the total power radiated can be calculated in a straightforward way. With the definition of $\mathbf{Q}(\mathbf{n})$ we can

write the angular dependence as

$$\begin{aligned}
 |[\mathbf{n} \times \mathbf{Q}(\mathbf{n})] \times \mathbf{n}|^2 &= \mathbf{Q}^* \cdot \mathbf{Q} - |\mathbf{n} \cdot \mathbf{Q}|^2 \\
 &= \sum_{\alpha, \beta, \gamma} Q_{\alpha\beta}^* Q_{\alpha\gamma} n_\beta n_\gamma - \sum_{\alpha, \beta, \gamma, \delta} Q_{\alpha\beta}^* Q_{\gamma\delta} n_\alpha n_\beta n_\gamma n_\delta
 \end{aligned} \quad (9.46)$$

The necessary angular integrals over products of the rectangular components of \mathbf{n} are readily found to be

$$\left. \begin{aligned} \int n_\beta n_\gamma d\Omega &= \frac{4\pi}{3} \delta_{\beta\gamma} \\ \int n_\alpha n_\beta n_\gamma n_\delta d\Omega &= \frac{4\pi}{15} (\delta_{\alpha\beta} \delta_{\gamma\delta} + \delta_{\alpha\gamma} \delta_{\beta\delta} + \delta_{\alpha\delta} \delta_{\beta\gamma}) \end{aligned} \right\} \quad (9.47)$$

Then we find

$$\int |[\mathbf{n} \times \mathbf{Q}(\mathbf{n})] \times \mathbf{n}|^2 d\Omega = 4\pi \left\{ \frac{1}{3} \sum_{\alpha, \beta} |Q_{\alpha\beta}|^2 - \frac{1}{15} \left[\sum_{\alpha} Q_{\alpha\alpha}^* \sum_{\gamma} Q_{\gamma\gamma} + 2 \sum_{\alpha, \beta} |Q_{\alpha\beta}|^2 \right] \right\} \quad (9.48)$$

Since $Q_{\alpha\beta}$ is a tensor whose main diagonal sum is zero, the first term in the square brackets vanishes identically. Thus we obtain the final result for the total power radiated by a quadrupole source:

$$P = \frac{ck^6}{360} \sum_{\alpha, \beta} |Q_{\alpha\beta}|^2 \quad (9.49)$$

The radiated power varies as the sixth power of the frequency for fixed quadrupole moments, compared to the fourth power for dipole radiation.

A simple example of a radiating quadrupole source is an oscillating spheroidal distribution of charge. The off-diagonal elements of $Q_{\alpha\beta}$ vanish. The diagonal elements may be written

$$Q_{33} = Q_0, \quad Q_{11} = Q_{22} = -\frac{1}{2}Q_0 \quad (9.50)$$

Then the angular distribution of radiated power is

$$\frac{dP}{d\Omega} = \frac{ck^6}{128\pi} Q_0^2 \sin^2 \theta \cos^2 \theta \quad (9.51)$$

This is a four-lobed pattern, as shown in Fig. 9.2, with maxima at $\theta = \pi/4$ and $3\pi/4$. The total power radiated by this quadrupole is

$$P = \frac{ck^6 Q_0^2}{240} \quad (9.52)$$

The labor involved in manipulating higher terms in expansion (9.9) of the vector potential (9.8) becomes increasingly prohibitive as the expansion is extended beyond the electric quadrupole terms. Another disadvantage of the present approach is that physically distinct fields such as those of the magnetic

Fig. 9.2 Quadrupole radiation pattern.

dipole and the electric quadrupole must be disentangled from the separate terms in (9.9). Finally, the present technique is useful only in the long-wavelength limit. A systematic development of multipole radiation is given in Chapter 16. It involves a fairly elaborate mathematical apparatus, but the price paid is worth while. The treatment allows all multipole orders to be handled in the same way; the results are valid for all wavelengths; the physically different electric and magnetic multipoles are clearly separated from the beginning.

9.4 Center-fed Linear Antenna

(a) Approximation of Sinusoidal Current

For certain radiating systems the geometry of current flow is sufficiently simple that integral (9.3) for the vector potential can be found in relatively simple, closed form if the form of the current is assumed known. As an example of such a system we consider a thin, linear antenna of length d which is excited across a small gap at its midpoint. The antenna is assumed to be oriented along the z axis with its gap at the origin, as indicated in Fig. 9.3. If damping due to the emission of radiation is neglected and the antenna is thin enough, the current along the antenna can be taken as sinusoidal in time and space with wave number $k = \omega/c$, and is symmetric on the two arms of the antenna. The current vanishes at the ends of the antenna. Hence the current density can be written

$$\mathbf{J}(\mathbf{x}) = I \sin \left(\frac{kd}{2} - k|z| \right) \delta(x) \delta(y) \mathbf{e}_3 \quad (9.53)$$

Fig. 9.3 Center-fed, linear antenna.

for $|z| < (d/2)$. The delta functions assure that the current flows only along the z axis. I is the peak value of the current if $kd \geq \pi$. The current at the gap is $I_0 = I \sin(kd/2)$.

With the current density (9.53) the vector potential is in the z direction and in the radiation zone has the form [from (9.8)]:

$$\mathbf{A}(\mathbf{x}) = \epsilon_3 \frac{Ie^{ikr}}{cr} \int_{-(d/2)}^{(d/2)} \sin\left(\frac{kd}{2} - k|z|\right) e^{-ikz \cos \theta} dz \quad (9.54)$$

The result of straightforward integration is

$$\mathbf{A}(\mathbf{x}) = \epsilon_3 \frac{2Ie^{ikr}}{ckr} \left[\frac{\cos\left(\frac{kd}{2} \cos \theta\right) - \cos\left(\frac{kd}{2}\right)}{\sin^2 \theta} \right] \quad (9.55)$$

Since the magnetic induction in the radiation zone is given by $\mathbf{B} = ik\mathbf{n} \times \mathbf{A}$, its magnitude is $|\mathbf{B}| = k \sin \theta |\mathbf{A}_3|$. Thus the time-averaged power radiated per unit solid angle is

$$\frac{dP}{d\Omega} = \frac{I^2}{2\pi c} \left| \frac{\cos\left(\frac{kd}{2} \cos \theta\right) - \cos\left(\frac{kd}{2}\right)}{\sin \theta} \right|^2 \quad (9.56)$$

The electric vector is in the direction of the component of \mathbf{A} perpendicular to \mathbf{n} . Consequently the polarization of the radiation lies in the plane containing the antenna and the radius vector to the observation point.

The angular distribution (9.56) depends on the value of kd . In the long-wavelength limit ($kd \ll 1$) it is easy to show that it reduces to the dipole result (9.28). For the special values $kd = \pi(2\pi)$, corresponding to a half (two halves) of a wavelength of current oscillation along the antenna, the angular distributions

are

$$\frac{dP}{d\Omega} = \frac{I^2}{2\pi c} \begin{cases} \frac{\cos^2\left(\frac{\pi}{2} \cos \theta\right)}{\sin^2 \theta}, & kd = \pi \\ \frac{4 \cos^4\left(\frac{\pi}{2} \cos \theta\right)}{\sin^2 \theta}, & kd = 2\pi \end{cases} \quad (9.57)$$

These angular distributions are shown in Chapter 16 in Fig. 16.4, where they are compared to multipole expansions. The half-wave antenna distribution is seen to be quite similar to a simple dipole pattern, but the full-wave antenna has a considerably sharper distribution.

The full-wave antenna distribution can be thought of as due to the coherent superposition of the fields of two half-wave antennas, one above the other, excited in phase. The intensity at $\theta = \pi/2$, where the waves add algebraically, is 4 times that of a half-wave antenna. At angles away from $\theta = \pi/2$ the amplitudes tend to interfere, giving the narrower pattern. By suitable arrangement of a set of basic antennas, such as the half-wave antenna, with the phasing of the currents appropriately chosen, arbitrary radiation patterns can be formed by coherent superposition. The interested reader should refer to the electrical engineering literature for detailed treatments of antenna arrays.

(b) *The Antenna as a Boundary-Value Problem*

The assumption that the current is sinusoidal, or indeed any other *known* form, along the antenna is unjustified, except for infinitely thin conductors. A finite sized antenna with a given type of excitation is actually a complicated boundary-value problem. Without attempting solution of such problems, we give some preliminary considerations on setting up the boundary-value problem for a straight antenna with circular cross section of radius a and length d , of which the center-fed antenna of Fig. 9.3 is one example. We assume that the conductor is perfectly conducting and has a small enough radius compared to both a wavelength and the length that current flow on the surface has only a longitudinal (z) component, and that the fields have azimuthal symmetry. Then the vector potential \mathbf{A} will have only a z component. With harmonic time dependence of frequency ω and in the Lorentz gauge, the scalar potential and the electric field are given in terms of \mathbf{A} by

$$\begin{aligned} \Phi(\mathbf{x}) &= \frac{-i}{k} \nabla \cdot \mathbf{A} \\ \mathbf{E}(\mathbf{x}) &= \frac{i}{k} [\nabla(\nabla \cdot \mathbf{A}) + k^2 \mathbf{A}] \end{aligned} \quad (9.58)$$

Since $\mathbf{A} = \epsilon_3 A_z(\mathbf{x})$, the z -component of electric field is

$$E_z(\mathbf{x}) = \frac{i}{k} \left(\frac{\partial^2}{\partial z^2} + k^2 \right) A_z(\mathbf{x})$$

But on the surface of the perfectly conducting antenna the tangential component of \mathbf{E} vanishes. We thus establish the important fact that *the vector potential A_z (and also the scalar potential) on the surface of the antenna are strictly sinusoidal*;

$$\left(\frac{\partial^2}{\partial z^2} + k^2 \right) A_z(\rho = a, z) = 0 \quad (9.59)$$

This is an exact statement, in contrast to the much rougher assumption that the current is sinusoidal.

An integral equation for the current can be found from (9.3). If the total current flow in the z direction is $I(z)$, then (9.3) gives for A_z on the surface of the antenna,

$$A_z(\rho = a, z) = \frac{1}{c} \int_{z_0}^{z_0+d} I(z') K(z-z') dz'$$

where

$$K(z-z') = \frac{1}{\pi} \int_0^\pi \frac{e^{ik\sqrt{(z-z')^2 + 4a^2 \sin^2 \beta}}}{\sqrt{(z-z')^2 + 4a^2 \sin^2 \beta}} d\beta \quad (9.60)$$

is the azimuthal average of the Green function e^{ikR}/R . The condition (9.59) leads to the integro-differential equation,

$$0 = \left(\frac{d^2}{dz^2} + k^2 \right) \int_{z_0}^{z_0+d} I(z') K(z-z') dz' \quad (9.61)$$

This can be regarded as a differential equation for the integral, or equivalently one can integrate (9.59) and equate it to $A_z(\rho = a, z)$. The result is the integral equation,

$$a_1 \cos kz + a_2 \sin kz = \int_{z_0}^{z_0+d} I(z') K(z-z') dz'$$

The constants a_1 and a_2 are determined by the method of excitation and by the boundary conditions that the current vanishes at the ends of the antenna.

The solution of the integral equation is not easy. From the form of (9.60) it is clear that when $z' \approx z$ care must be taken and the finite radius is important. For $a \rightarrow 0$, the current can be shown to be sinusoidal, but the expansion parameter for corrections turns out to be the reciprocal of $\ln(d/a)$. This means that even for $d/a = 10^3$ there can be corrections of the order of 10 to 15 per cent. When there is a current node near the place of excitation, such corrections can change the antenna's input impedance drastically. Various approximate methods of solution of (9.61) are described by Jones. A detailed discussion of his version of the

theory and the results of numerical calculations for the current, resistance, and reactance of a linear center-fed antenna are given by *Hallén*. Other references are cited in the suggested reading at the end of the chapter.

9.5 Multipole Expansion for Localized Source or Aperture in Wave Guide

If a source in the form of a probe or loop or aperture in a wave guide is sufficiently small in dimensions compared to the distances over which the fields vary appreciably, it can be usefully approximated by its lowest order multipole moments, usually electric and magnetic dipoles. Different sources possessing the same lowest order multipole moments will produce sensibly the same excitations in the wave guide. Often the electric dipole or magnetic dipole moments can be calculated from static fields, or even estimated geometrically. Even if the source is not truly small, the multipole expansion gives a qualitative, and often semiquantitative, understanding of its properties.

(a) Current Source Inside Guide

In Section 8.11 it was shown that the amplitudes $A_\lambda^{(\pm)}$ for excitation of the λ th mode are proportional to the integral,

$$\int \mathbf{J} \cdot \mathbf{E}_\lambda^{(\mp)} d^3x$$

where the integral is extended over the region where \mathbf{J} is different from zero. If the mode fields $\mathbf{E}_\lambda^{(\mp)}$ do not vary appreciably over the source, they can be expanded in Taylor series around some suitably chosen origin. The integral is thus written, dropping the sub- and superscripts on $\mathbf{E}_\lambda^{(\mp)}$,

$$\int \mathbf{J} \cdot \mathbf{E} d^3x = \sum_{\alpha=1}^3 \int J_\alpha(\mathbf{x}) \left[E_\alpha(0) + \sum_{\beta=1}^3 x_\beta \frac{\partial E_\alpha}{\partial x_\beta}(0) + \cdots \right] d^3x \quad (9.62)$$

From (9.14) and (9.17) we see that the first term is

$$\mathbf{E}(0) \cdot \int \mathbf{J}(\mathbf{x}) d^3x = -i\omega \mathbf{p} \cdot \mathbf{E}(0) \quad (9.63)$$

where \mathbf{p} is the electric dipole moment of the source:

$$\mathbf{p} = \frac{i}{\omega} \int \mathbf{J}(\mathbf{x}) d^3x$$

This can be transformed into the more familiar form (9.17) by the means of the steps in (9.14), provided the surface integral at the walls of the wave guide can be dropped. This necessitates choosing the origin for the multipole expansion such that $J_\alpha x_\beta$ vanishes at the walls. This remark applies to all the multipole moments. The use of the forms involving the electric and magnetic charge densities ρ and ρ_M requires that $(x_\alpha J_\beta \pm x_\beta J_\alpha) x_\gamma \cdots x_\nu$ vanish at the walls of the guide. The above

form for the electric dipole and the usual expression (9.34) for the magnetic dipole are correct as they stand, without concern about choice of origin.

The second term in (9.62) is of the same general form as (9.30) and is handled the same way. The product $J_\alpha x_\beta$ is written as the sum of symmetric and antisymmetric terms, just as in (9.31):

$$\begin{aligned} \sum_{\alpha,\beta} J_\alpha x_\beta \frac{\partial E_\alpha}{\partial x_\beta}(0) &= \frac{1}{4} \sum_{\alpha,\beta} (J_\alpha x_\beta - J_\beta x_\alpha) \left[\frac{\partial E_\alpha}{\partial x_\beta}(0) - \frac{\partial E_\beta}{\partial x_\alpha}(0) \right] \\ &\quad + \frac{1}{2} \sum_{\alpha,\beta} (J_\alpha x_\beta + J_\beta x_\alpha) \frac{\partial E_\alpha}{\partial x_\beta}(0) \end{aligned} \quad (9.64)$$

The first (antisymmetric) part has been written so that the magnetic moment density and the curl of the electric field are clearly visible. With the help of Faraday's law $\nabla \times \mathbf{E} = i\omega \mathbf{B}/c$, the antisymmetric contribution to the right side of (9.62) can be written

$$\left[\sum_{\alpha,\beta} J_\alpha x_\beta \frac{\partial E_\alpha}{\partial x_\beta}(0) \right]_{\text{antisym}} d^3x = i\omega \mathbf{m} \cdot \mathbf{B}(0) \quad (9.65)$$

where \mathbf{m} is the magnetic dipole moment (9.34) of the source. Equations (9.63) and (9.65) give the leading order multipole moment contributions to the source integral (9.62).

Other terms in the expansion in (9.62) give rise to higher order multipoles. The symmetric part of (9.64) can be shown, just as in Section 9.3, to involve the *traceless electric quadrupole moment* (9.41). The first step is to note that if the surface integrals vanish (see above),

$$\int (J_\alpha x_\beta + J_\beta x_\alpha) d^3x = -i\omega \int x_\alpha x_\beta \rho(\mathbf{x}) d^3x$$

Then the second double sum in (9.64), integrated over the volume of the current distribution, takes the form

$$-\frac{i\omega}{2} \sum_{\alpha,\beta} \frac{\partial E_\alpha}{\partial x_\beta}(0) \int \rho(\mathbf{x}) x_\alpha x_\beta d^3x$$

The value of the double sum is unchanged by the replacement $x_\alpha x_\beta \rightarrow (x_\alpha x_\beta - \frac{1}{3} r^2 \delta_{\alpha\beta})$ because $\nabla \cdot \mathbf{E} = 0$. Thus the symmetric part of the second term in (9.62) is

$$\left[\sum_{\alpha,\beta} J_\alpha x_\beta \frac{\partial E_\alpha}{\partial x_\beta}(0) \right]_{\text{sym}} d^3x = -\frac{i\omega}{6} \sum_{\alpha,\beta} Q_{\alpha\beta} \frac{\partial E_\alpha}{\partial x_\beta}(0) \quad (9.66)$$

Similarly an antisymmetric part of the next terms in (9.62), involving $x_\beta x_\gamma$, gives a contribution

$$\left[\frac{1}{2} \sum_{\alpha,\beta,\gamma} J_\alpha x_\beta x_\gamma \frac{\partial^2 E_\alpha}{\partial x_\beta \partial x_\gamma}(0) \right]_{\text{antisym in } (\alpha, \beta)} d^3x = \frac{i\omega}{6} \sum_{\alpha,\beta} Q_{\alpha\beta}^M \frac{\partial B_\alpha}{\partial x_\beta}(0) \quad (9.67)$$

where $Q_{\alpha\beta}^M$ is the *magnetic quadrupole moment* of the source, given by (9.41) with the electric charge density $\rho(\mathbf{x})$ replaced by the magnetic charge density,

$$\rho^M(\mathbf{x}) = -\nabla \cdot \mathcal{M} = -\frac{1}{2c} \nabla \cdot (\mathbf{x} \times \mathbf{J}) \quad (9.68)$$

If the various contributions are combined, the expression (8.140) for the amplitude $A_\lambda^{(\pm)}$ has as its multipole expansion,

$$A_\lambda^{(\pm)} = i \frac{2\pi\omega Z_\lambda}{c} \left\{ \mathbf{p} \cdot \mathbf{E}_\lambda^{(\mp)}(0) - \mathbf{m} \cdot \mathbf{B}_\lambda^{(\mp)}(0) + \frac{1}{6} \sum_{\alpha,\beta} \left[Q_{\alpha\beta} \frac{\partial E_{\lambda\alpha}^{(\mp)}}{\partial x_\beta}(0) - Q_{\alpha\beta}^M \frac{\partial B_{\lambda\alpha}^{(\mp)}}{\partial x_\beta}(0) \right] + \dots \right\} \quad (9.69)$$

It should be remembered that here the mode fields $E_\lambda^{(\pm)}$ are normalized according to (8.125). The expansion is most useful if the source is such that the series converges rapidly and is adequately approximated by its first terms. The positioning and orientation of probes or antennas in order to excite preferentially certain modes can be accomplished simply by considering the directions of the electric and magnetic dipole (or higher) moments of the source and the normal mode fields. For example, the excitation of TE modes, with their axial magnetic fields, can be produced by a magnetic dipole antenna whose dipole moment is parallel to the axis of the guide. TM modes cannot be excited by such an antenna, except via higher multipole moments.

(b) Aperture in Side Walls of Guide

Apertures in the walls of a wave guide can be considered as sources (or sinks) of energy. In Section 8.11 it was noted that if the guide walls have openings in the volume considered to contain the sources, the amplitudes $A_\lambda^{(\pm)}$ are given by (8.141) instead of (8.140). With the assumption that there is only one aperture, and no actual current density, the amplitude for excitation of the λ^{th} mode is

$$A_\lambda^{(\pm)} = -\frac{Z_\lambda}{2} \int_{\text{aperture}} \mathbf{n} \cdot (\mathbf{E} \times \mathbf{H}_\lambda^{(\mp)}) da \quad (9.70)$$

where \mathbf{n} is an *inwardly* directed normal and the integral is over the aperture in the walls of the guide. If the aperture is small compared to a wavelength or other scale of variation of the fields, the mode field $\mathbf{H}_\lambda^{(\mp)}$ can be expanded just as before. The lowest order term, with $\mathbf{H}_\lambda^{(\mp)}$ treated as constant over the aperture, evidently leads to a coupling of the magnetic dipole type. The next terms, with linear variation of the mode field, gives rise to electric dipole and magnetic quadrupole couplings, exactly as for (9.64)–(9.66), but with the roles of electric and magnetic interactions interchanged. The result is an expansion of (9.70) like (9.69):

$$A_\lambda^{(\pm)} = i \frac{\pi\omega Z_\lambda}{c} [\mathbf{p}_{\text{eff}} \cdot \mathbf{E}_\lambda^{(\mp)}(0) - \mathbf{m}_{\text{eff}} \cdot \mathbf{B}_\lambda^{(\mp)}(0) + \dots] \quad (9.71)$$

where the effective electric and magnetic dipole moments are

$$\left. \begin{aligned} \mathbf{p}_{\text{eff}} &= \frac{\epsilon \mathbf{n}}{4\pi} \int (\mathbf{x} \cdot \mathbf{E}_{\text{tan}}) da \\ \mathbf{m}_{\text{eff}} &= \frac{c}{2\pi i \mu \omega} \int (\mathbf{n} \times \mathbf{E}_{\text{tan}}) da \end{aligned} \right\} \quad (9.72)$$

In these expressions the integration is over the aperture, the electric field \mathbf{E}_{tan} is the exact tangential field in the opening, and in (9.71) the mode fields are evaluated at (the center of) the aperture. The effective moments (9.72) are the equivalent dipoles whose fields (9.18) and (9.35)–(9.36) represent the radiation fields of a small aperture in a flat, perfectly conducting screen (See Problem 9.15.). Comparison of (9.71) and (9.69) shows that the dipole moments (9.72) are only half as effective in producing a given amplitude as are the real dipole moments of a source located inside the guide. This can be pictured as because the effective dipoles of an aperture are in some sense half in and half out of the guide.

(c) Small Aperture in a Transverse Diaphragm

The subject of reflection and transmission by apertures in a transverse diaphragm has been discussed in Sections 8.12 and 8.13. For a small opening, however, it is useful to have a description in terms of effective multipole moments of the aperture, just as for openings in the side walls. For a transverse diaphragm the reflection and transmission coefficients are given by (8.144) and (8.145). With the use of (8.31), (8.145), which can also represent (8.144) when $\lambda = 1$, becomes

$$A_{\lambda}^{(+)} = A_{\lambda}^{(-)} = Z_{\lambda} \int (\mathbf{e}_3 \times \mathbf{E}_{\text{tan}}) \cdot \mathbf{H}_{\lambda} da \quad (9.73)$$

In the same spirit as above, the transverse magnetic field \mathbf{H}_{λ} is expanded in a Taylor series about a suitable origin in the small aperture. The structure of (9.73) is identical with (9.70) and the various terms in the expansion are the same. The lowest order multipoles give contributions

$$A_{\lambda}^{(+)} = A_{\lambda}^{(-)} = i \frac{2\pi\omega Z_{\lambda}}{c} [\mathbf{p}_{\text{eff}}^{(\pm)} \cdot \mathbf{E}_{\lambda}^{(\mp)}(0) - \mathbf{m}_{\text{eff}}^{(\pm)} \cdot \mathbf{B}_{\lambda}^{(\mp)}(0) + \dots] \quad (9.74)$$

For $\lambda = 1$, this gives the transmission amplitude, $T = 1 + R$. Equation (9.74) is exactly the same in form as (9.69), which applies to a localized current source within the guide. The effective dipole moments $\mathbf{p}_{\text{eff}}^{(\pm)}$ and $\mathbf{m}_{\text{eff}}^{(\pm)}$ are given by (9.72) with $\mathbf{n} = \pm \mathbf{e}_3$, and the integration is taken over the aperture with z constant. The choice of superscripts in (9.74) is unimportant as long as a consistent set is chosen. The superscripts (\pm) on the effective dipole moments corresponds to viewing the aperture from $z \gtrless 0$, as is discussed below.

(d) *Effective Dipole Moments of Apertures*

On first encounter the effective dipole moments (9.72) are somewhat mysterious. As already mentioned, they have a precise meaning in terms of the electric and magnetic dipole parts of the multipole expansion of the fields radiated through an aperture in a flat perfectly conducting screen (Problem 9.15). For small apertures they can also be related to the solutions of appropriate static or quasi-static boundary-value problems. Such problems have already been discussed (Sections 3.13 and 5.13), and the results will be appropriated below.

If an aperture is very small compared to the distance over which the fields change appreciably, the boundary-value problem can be approximated by one in which the fields “far from the aperture” (measured in units of the aperture dimension) are those that would exist if the aperture were absent. Except for very elongated apertures, it will be sufficiently accurate to take the surface to be flat and the “asymptotic” fields to be the same in all directions away from the aperture. For an opening in a perfectly conducting surface, then, the boundary-value problem is specified by the *normal* electric field \mathbf{E}_0 and the *tangential* magnetic field \mathbf{B}_0 that would exist in the absence of the opening. The fields \mathbf{E}_0 and \mathbf{B}_0 are themselves the result of some boundary-value problem, of propagation in a wave guide or reflection of a plane wave from a screen, for example. But for the purpose at hand, they are treated as given. To lowest order their time dependence can be ignored, provided the effective electric dipole moment is related to \mathbf{E}_0 and the magnetic moment to \mathbf{B}_0 . (See, however, Problem 9.9.)

The exact form of the fields around the opening depends on its shape, but some qualitative observations can be made by merely examining the general behavior of the lines of force. Outside a sphere enclosing the aperture the fields may be represented by a multipole expansion. The leading terms will be dipole fields. Figure 9.4 shows the qualitative behavior. The loop of magnetic field protruding above the plane has the appearance of a line of force from a magnetic dipole whose moment is directed oppositely to \mathbf{B}_0 , as indicated by the direction of the moment $\mathbf{m}^{(+)}$ shown below. The magnetic field below the plane can be viewed as the unperturbed \mathbf{B}_0 , plus an opposing dipole field (shown dotted in the figure) whose moment is oriented parallel to \mathbf{B}_0 (denoted by $\mathbf{m}^{(-)}$ below). Similarly, the electric field lines above the plane appear to originate from a vertical dipole moment $\mathbf{p}^{(+)}$ directed along \mathbf{E}_0 , while below the plane the field has the appearance of the unperturbed normal field \mathbf{E}_0 , plus the field from a dipole $\mathbf{p}^{(-)}$, directed oppositely to \mathbf{E}_0 . The use of effective dipole fields is of course restricted to regions some distance from the aperture. Right in the aperture the fields bear no resemblance to dipole fields. Nevertheless, the dipole approximation is useful qualitatively everywhere, and the effective moments are all that are needed to evaluate the couplings of small apertures.

The preceding qualitative discussion has one serious deficiency. While it is correct that the *electric* dipole moment is always directed parallel or antiparallel to \mathbf{E}_0 and so is normal to the aperture, the *magnetic* dipole moment is not

Fig. 9.4 Distortion of the tangential magnetic field (on the left) and normal electric field (on the right) by a small aperture in a perfectly conducting surface. The effective dipole moments, as viewed from above and below the surface, are indicated beneath.

necessarily parallel or antiparallel to \mathbf{B}_0 . There are two directions in the tangent plane, and the relative orientation of the aperture and the direction of \mathbf{B}_0 are relevant in determining the direction of \mathbf{m}_{eff} . Since the effective moments are obviously proportional to the field strength, it is appropriate to speak of the *electric and magnetic polarizabilities* of the aperture. The dipole moments can be written

$$\mathbf{p}_{\text{eff}} = \gamma^E \mathbf{E}_0 \quad (9.75)$$

$$(\mathbf{m}_{\text{eff}})_\alpha = \sum_\beta \gamma_{\alpha\beta}^M (\mathbf{B}_0)_\beta$$

where γ^E is the scalar electric polarizability and $\gamma_{\alpha\beta}^M$ is the 2×2 magnetic polarizability tensor. The magnetic tensor can be diagonalized by choosing principal axes for the aperture. There are thus three polarizabilities (one electric and two magnetic) to characterize an arbitrary small aperture. It should be remembered that the signs of the γ 's in (9.75) depend on the side of the surface from which the dipole is viewed, as shown in Figure 9.4. If there are fields on both sides of the surface, the expressions in (9.75) must be modified. For example, if there is a vertically directed electric field \mathbf{E}_1 above the surface on the right in Fig. 9.4, as well as \mathbf{E}_0 below, then \mathbf{E}_0 in (9.75) is replaced by $(\mathbf{E}_0 - \mathbf{E}_1)$. Other possibilities can be worked out from (9.75) by linear superposition.

The polarizabilities γ^E and $\gamma_{\alpha\beta}^M$ have the dimensions of length cubed. If a typical dimension of the aperture is d , then it can be expected that the polarizabilities will be d^3 times numerical coefficients of the order of unity, or smaller. The expression (9.72) for \mathbf{p}_{eff} can be seen to be of the form to yield such a result, since \mathbf{E}_{tan} is proportional to E_0 , and the two-dimensional integral will

give E_0 times the cube of a length that is characteristic of the aperture. Furthermore, the vectorial properties of \mathbf{p}_{eff} in (9.72) corresponds to (9.75). On the other hand, the expression in (9.72) for \mathbf{m}_{eff} is less transparently of the proper form, even though dimensionally correct. Some integrations by parts and use of the Maxwell equations puts it into the equivalent and more satisfying form:

$$\mathbf{m}_{\text{eff}} = \frac{1}{2\pi\mu} \int \mathbf{x}(\mathbf{n} \cdot \mathbf{B}) da \quad (9.76)$$

where $\mathbf{n} \cdot \mathbf{B}$ is the exact normal component of \mathbf{B} in the aperture and the integration is over the plane of the aperture. It is now evident that the connection between \mathbf{B}_0 and \mathbf{m}_{eff} is of the general form shown in (9.75). For a circular opening of radius R the effective dipole moments can be taken from the static solutions of Sections 3.13 and 5.13. The results are

$$\mathbf{p}_{\text{eff}} = -\frac{R^3}{3\pi} \mathbf{E}_0, \quad \mathbf{m}_{\text{eff}} = \frac{2R^3}{3\pi} \mathbf{B}_0 \quad (9.77)$$

where the signs are appropriate for the apertures viewed from the side of the surface where \mathbf{E} and \mathbf{B} are nonvanishing, as can be checked from Fig. 9.4. The electric and magnetic polarizabilities are thus

$$\gamma^E = -\frac{R^3}{3\pi}, \quad \gamma_{\alpha\beta}^M = \frac{2R^3}{3\pi} \delta_{\alpha\beta} \quad (9.78)$$

The use of effective dipole moments to describe the electromagnetic properties of small holes can be traced back to Lord Rayleigh.* The general theory was developed by H. A. Bethe† and has been applied fruitfully to wave guide and diffraction problems. Of significance in practical applications is the fact that the effective dipole moments of arbitrary apertures can be determined experimentally by electrolytic tank measurements.‡

Examples of the use of multipoles to describe excitation and scattering in wave guides and diffraction are left to several problems at the end of the chapter. Other material can be found in the list of suggested reading.

9.6 Scattering at Long Wavelengths

(a) Scattering by Dipoles Induced in Small Scatterers

The scattering of electromagnetic waves by systems whose individual dimensions are small compared with a wavelength is a common and important

* Lord Rayleigh, *Phil. Mag.* **XLIV**, 28, (1897), reprinted in his *Scientific Papers*, Vol. IV, p. 305.

† H. A. Bethe, *Phys. Rev.* **66**, 163 (1944).

‡ S. B. Cohn, *Proc. I.R.E.* **39**, 1416 (1951); **40**, 1069 (1952).

occurrence. In such interactions it is convenient to think of the incident (radiation) fields as inducing electric and magnetic multipoles that oscillate in definite phase relationship with the incident wave and radiate energy in directions other than the direction of incidence. The exact form of the angular distribution of radiated energy is governed by the *coherent superposition* of multipoles induced by the incident fields, and will in general depend on the state of polarization of the incident wave. If the wavelength of the radiation is long compared to the size of the scatterer, only the lowest multipoles, usually electric and magnetic dipoles, are important. Furthermore, in these circumstances the induced dipoles can be calculated from static or quasi-static boundary-value problems, just as for the small apertures of the previous section.

The customary basic situation is for a plane monochromatic wave to be incident on a scatterer. For simplicity the surrounding medium is taken to have $\mu = \epsilon = 1$. If the incident direction is defined by the unit vector \mathbf{n}_0 , and the incident polarization vector is $\boldsymbol{\epsilon}_0$, the incident fields are

$$\begin{aligned}\mathbf{E}_{\text{inc}} &= \boldsymbol{\epsilon}_0 E_0 e^{ik\mathbf{n}_0 \cdot \mathbf{x}} \\ \mathbf{B}_{\text{inc}} &= \mathbf{n}_0 \times \mathbf{E}_{\text{inc}}\end{aligned}\quad (9.79)$$

where $k = \omega/c$ and a time-dependence $e^{-i\omega t}$ is understood. These fields induce dipole moments \mathbf{p} and \mathbf{m} in the small scatterer and these dipoles radiate energy in all directions, as described in Sections 9.2 and 9.3. Far away from the scatterer, the scattered (radiated) fields are found from (9.19) and (9.36) to be

$$\begin{aligned}\mathbf{E}_{\text{sc}} &= k^2 \frac{e^{ikr}}{r} [(\mathbf{n} \times \mathbf{p}) \times \mathbf{n} - \mathbf{n} \times \mathbf{m}] \\ \mathbf{B}_{\text{sc}} &= \mathbf{n} \times \mathbf{E}_{\text{sc}}\end{aligned}\quad (9.80)$$

where \mathbf{n} is a unit vector in the direction of observation and r is the distance away from scatterer. The power radiated in the direction \mathbf{n} with polarization $\boldsymbol{\epsilon}$, per unit solid angle, per unit incident flux (power per unit area) in the direction \mathbf{n}_0 with polarization $\boldsymbol{\epsilon}_0$, is a quantity with dimensions of area per unit solid angle. It is called the *differential scattering cross section*.*

$$\frac{d\sigma}{d\Omega}(\mathbf{n}, \boldsymbol{\epsilon}; \mathbf{n}_0, \boldsymbol{\epsilon}_0) = \frac{r^2 \frac{c}{8\pi} |\boldsymbol{\epsilon}^* \cdot \mathbf{E}_{\text{sc}}|^2}{\frac{c}{8\pi} |\boldsymbol{\epsilon}_0^* \cdot \mathbf{E}_{\text{inc}}|^2} \quad (9.81)$$

The complex conjugation of the polarization vectors in (9.81) is important for the correct handling of circular polarization, as has been mentioned in Section

* In the engineering literature the term *bistatic cross section* is used for $4\pi (d\sigma/d\Omega)$.

7.2. With (9.80) and (9.79), the differential cross section can be written

$$\frac{d\sigma}{d\Omega}(\mathbf{n}, \boldsymbol{\epsilon}; \mathbf{n}_0, \boldsymbol{\epsilon}_0) = \frac{k^4}{E_0^2} |\boldsymbol{\epsilon}^* \cdot \mathbf{p} + (\mathbf{n} \times \boldsymbol{\epsilon}^*) \cdot \mathbf{m}|^2 \quad (9.82)$$

The dependence of the cross section on \mathbf{n}_0 and $\boldsymbol{\epsilon}_0$ is implicitly contained in the dipole moments \mathbf{p} and \mathbf{m} . The variation of the differential (and total) scattering cross section with wave number as k^4 (or in wavelength as λ^{-4}) is an almost universal characteristic of the scattering of long wavelength radiation by any finite system. This dependence on frequency is known as *Rayleigh's law*. Only if both static dipole moments vanish does the scattering fail to obey Rayleigh's law; the scattering is then via quadrupole or higher multipoles (or frequency-dependent dipole moments) and varies as ω^6 or higher. Sometimes the dipole scattering is known as *Rayleigh scattering* but this term is usually reserved for the *incoherent* scattering by a collection of dipole scatterers.

(b) *Scattering by a Small Dielectric Sphere*

As a first, very simple example of dipole scattering we consider a small dielectric sphere of radius a with $\mu=1$ and a uniform isotropic dielectric constant $\epsilon(\omega)$. From Section 4.4, in particular (4.56), the electric dipole moment is found to be

$$\mathbf{p} = \left(\frac{\epsilon-1}{\epsilon+2} \right) a^3 \mathbf{E}_{\text{inc}} \quad (9.83)$$

There is no magnetic dipole moment. The differential scattering cross section is

$$\frac{d\sigma}{d\Omega} = k^4 a^6 \left| \frac{\epsilon-1}{\epsilon+2} \right|^2 |\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0|^2 \quad (9.84)$$

The polarization dependence of (9.84) is typical of purely electric dipole scattering. The scattered radiation is linearly polarized in the plane defined by the dipole moment direction ($\boldsymbol{\epsilon}_0$) and the unit vector \mathbf{n} .

Typically the incident radiation is unpolarized. It is then of interest to ask for the angular distribution of scattered radiation of a definite state of linear polarization. The cross section (9.84) is averaged over initial polarization $\boldsymbol{\epsilon}_0$ for a fixed choice of $\boldsymbol{\epsilon}$. Figure 9.5 shows a possible set of polarization vectors. The scattering plane is defined by the vectors \mathbf{n}_0 and \mathbf{n} . The polarization vectors $\boldsymbol{\epsilon}_0^{(1)}$ and $\boldsymbol{\epsilon}^{(1)}$ are in this plane, while $\boldsymbol{\epsilon}_0^{(2)} = \boldsymbol{\epsilon}^{(2)}$ is perpendicular to it. The differential cross sections for scattering with polarizations $\boldsymbol{\epsilon}^{(1)}$ and $\boldsymbol{\epsilon}^{(2)}$, averaged over initial polarizations, are easily shown to be

$$\begin{aligned} \frac{d\sigma_{\parallel}}{d\Omega} &= \frac{k^4 a^6}{2} \left| \frac{\epsilon-1}{\epsilon+2} \right|^2 \cos^2 \theta \\ \frac{d\sigma_{\perp}}{d\Omega} &= \frac{k^4 a^6}{2} \left| \frac{\epsilon-1}{\epsilon+2} \right|^2 \end{aligned} \quad (9.85)$$

Fig. 9.5 Polarization and propagation vectors for the incident and scattered radiation.

where the subscripts \parallel and \perp indicate polarization parallel to and perpendicular to the scattering plane, respectively. The polarization $\Pi(\theta)$ of the scattered radiation is defined by

$$\Pi(\theta) = \frac{\frac{d\sigma_{\perp}}{d\Omega} - \frac{d\sigma_{\parallel}}{d\Omega}}{\frac{d\sigma_{\perp}}{d\Omega} + \frac{d\sigma_{\parallel}}{d\Omega}} \quad (9.86)$$

From (9.85) we find for the (electric dipole) scattering by a small dielectric sphere,

$$\Pi(\theta) = \frac{\sin^2 \theta}{1 + \cos^2 \theta} \quad (9.87)$$

The differential cross section, summed over scattered polarization, is

$$\frac{d\sigma}{d\Omega} = k^4 a^6 \left| \frac{\epsilon - 1}{\epsilon + 2} \right|^2 \cdot \frac{1}{2} (1 + \cos^2 \theta) \quad (9.88)$$

and the total scattering cross section is

$$\sigma = \int \frac{d\sigma}{d\Omega} d\Omega = \frac{8\pi}{3} k^4 a^6 \left| \frac{\epsilon - 1}{\epsilon + 2} \right|^2 \quad (9.89)$$

The differential cross section (9.88) and the polarization of the scattered radiation (9.87) are shown as functions of $\cos \theta$ in Fig. 9.6. The polarization $\Pi(\theta)$ has its maximum at $\theta = \pi/2$. At this angle the scattered radiation is 100 per cent linearly polarized perpendicular to the scattering plane, and for an appreciable range of angles on either side of $\theta = \pi/2$ is quite significantly polarized. The polarization characteristics of the blue sky are an illustration of this phenomenon, and are, in fact, the motivation that led Rayleigh first to

consider the problem. The reader can verify the general behavior on a sunny day with a sheet of linear polarizer or suitable sun glasses.

(c) *Scattering by a Small Perfectly Conducting Sphere*

An example with interesting aspects involving coherence between different multipoles is the scattering by a small perfectly conducting sphere of radius a . The electric dipole moment of such a sphere was shown in Section 2.5 to be

$$\mathbf{p} = a^3 \mathbf{E}_{\text{inc}} \quad (9.90)$$

The sphere also possesses a magnetic dipole moment. For a perfectly conducting sphere the boundary condition on the magnetic field is that the normal component of \mathbf{B} vanishes at $r = a$. Either by analogy with the dielectric sphere in a uniform electric field (Section 4.4) with $\epsilon = 0$, or from the magnetically permeable sphere (Section 5.11) with $\mu = 0$, or by a simple direct calculation, it is found that the magnetic moment of the small sphere is

$$\mathbf{m} = -\frac{a^3}{2} \mathbf{B}_{\text{inc}} \quad (9.91)$$

For a linearly polarized incident wave the two dipoles are at right angles to each other and to the incident direction.

The differential cross section (9.82) is

$$\frac{d\sigma}{d\Omega}(\mathbf{n}, \boldsymbol{\epsilon}; \mathbf{n}_0, \boldsymbol{\epsilon}_0) = k^4 a^6 |\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0 - \frac{1}{2}(\mathbf{n} \times \boldsymbol{\epsilon}^*) \cdot (\mathbf{n}_0 \times \boldsymbol{\epsilon}_0)|^2 \quad (9.92)$$

Fig. 9.6 Differential scattering cross section (9.88) and the polarization of scattered radiation (9.87) for a small dielectric sphere (dipole approximation).

The polarization properties and the angular distribution of scattered radiation are more complicated than for the dielectric sphere. The cross sections analogous to (9.85), for polarization of the scattered radiation parallel to and perpendicular to the plane of scattering, with unpolarized radiation incident, are

$$\begin{aligned}\frac{d\sigma_{\parallel}}{d\Omega} &= \frac{k^4 a^6}{2} |\cos \theta - \tfrac{1}{2}|^2 \\ \frac{d\sigma_{\perp}}{d\Omega} &= \frac{k^4 a^6}{2} |1 - \tfrac{1}{2} \cos \theta|^2\end{aligned}\quad (9.93)$$

The differential cross section summed over both states of scattered polarization can be written

$$\frac{d\sigma}{d\Omega} = k^4 a^6 \left[\frac{5}{8} (1 + \cos^2 \theta) - \cos \theta \right] \quad (9.94)$$

while the polarization (9.86) is

$$\Pi(\theta) = \frac{3 \sin^2 \theta}{5(1 + \cos^2 \theta) - 8 \cos \theta} \quad (9.95)$$

The cross section and polarization are plotted versus $\cos \theta$ in Fig. 9.7. The cross section has a *strong backward peaking* caused by electric dipole-magnetic dipole interference. The polarization reaches $\Pi = +1$ at $\theta = 60^\circ$ and is positive through the whole angular range. The polarization thus tends to be similar to that for a small dielectric sphere, as shown in Fig. 9.6, even though the

Fig. 9.7 Differential scattering cross section (9.94) and polarization of scattered radiation (9.95) for a small perfectly conducting sphere (electric and magnetic dipole approximation).

angular distributions are quite different. The total scattering cross section is $\sigma = 10\pi k^4 a^6/3$, of the same order of magnitude as for the dielectric sphere (9.89) if $(\epsilon - 1)$ is not small.

Dipole scattering with its ω^4 dependence on frequency can be viewed as the lowest order approximation in an expansion in kd , where d is a length typical of the dimensions of the scatterer. In the domain $kd \sim 1$, more than the lowest order multipoles must be considered. Then the discussion is best accomplished by use of a systematic expansion in spherical multipole fields. These are treated in Chapter 16, where the scattering by a conducting sphere is examined from this point of view. When $kd \gg 1$, approximation methods of a different sort can be employed, as is illustrated in Section 13 of this chapter. Whole books are devoted to the scattering of light by spherical particles possessing arbitrary μ , ϵ , σ . Some references to this literature are given at the end of the chapter.

(d) Collection of Scatterers

As a final remark we note that if the scattering system consists of a number of small scatterers with fixed spatial separations, each scatterer generates an amplitude of the form (9.80). The scattering cross section results from a coherent superposition of the individual amplitudes. Because the induced dipoles are proportional to the incident fields, evaluated at the position \mathbf{x}_j of the j th scatterer, its moments will possess a phase factor, $e^{i\mathbf{k}\mathbf{n}_0 \cdot \mathbf{x}_j}$. Furthermore, if the observation point is far from the whole scattering system, (9.7) shows that the fields (9.80) for the j th scatterer will have a phase factor $e^{-i\mathbf{k}\mathbf{n} \cdot \mathbf{x}_j}$. The generalization of (9.82) for such a system is

$$\frac{d\sigma}{d\Omega} = \frac{k^4}{E_0^2} \left| \sum_j [\boldsymbol{\epsilon}^* \cdot \mathbf{p}_j + (\mathbf{n} \times \boldsymbol{\epsilon}^*) \cdot \mathbf{m}_j] e^{i\mathbf{q} \cdot \mathbf{x}_j} \right|^2 \quad (9.96)$$

where $\mathbf{q} = \mathbf{k}\mathbf{n}_0 - \mathbf{k}\mathbf{n}$ is the vectorial change in wave vector during the scattering.

The presence of the phase factors $e^{i\mathbf{q} \cdot \mathbf{x}_j}$ in (9.96) means that, apart from the forward direction where $\mathbf{q} = 0$, the scattering depends sensitively on the exact distribution of the scatterers in space. The general behavior can be illustrated by assuming that all the scatterers are identical. Then the cross section is the product of the cross section for one scatterer times a structure factor,*

$$\mathcal{F}(\mathbf{q}) = \left| \sum_j e^{i\mathbf{q} \cdot \mathbf{x}_j} \right|^2 \quad (9.97)$$

Written out as a factor times its complex conjugate, $\mathcal{F}(\mathbf{q})$ is

$$\mathcal{F}(\mathbf{q}) = \sum_j \sum_j e^{i\mathbf{q} \cdot (\mathbf{x}_j - \mathbf{x}_j')}$$

* We do not consider here the effects of multiple scattering, that is, we assume that the mean free path for scattering is large compared to the dimensions of the scattering array.

If the scatterers are randomly distributed, the terms with $j \neq j'$ can be shown to give a negligible contribution. Only the terms with $j = j'$ are significant. Then $\mathcal{F}(\mathbf{q}) = N$, the total number of scatterers, and the scattering is said to be an *incoherent superposition* of individual contributions. If, on the other hand, the scatterers are very numerous and have a regular distribution in space, the structure factor effectively vanishes everywhere except in the forward direction. There is therefore no scattering by a very large regular array of scatterers, of which single crystals of transparent solids like rock salt or quartz are examples. What small amount of scattering does occur is caused by thermal vibrations away from the perfect lattice, or by impurities, etc. An explicit illustration, also providing evidence for a restriction of the above remarks to the long wavelength regime, is that of a simple cubic array of scattering centers. The structure factor is well known to be

$$\mathcal{F}(\mathbf{q}) = N^2 \left[\frac{\sin^2 \left(\frac{N_1 q_1 a}{2} \right)}{N_1^2 \sin^2 \left(\frac{q_1 a}{2} \right)} \cdot \frac{\sin^2 \left(\frac{N_2 q_2 a}{2} \right)}{N_2^2 \sin^2 \left(\frac{q_2 a}{2} \right)} \cdot \frac{\sin^2 \left(\frac{N_3 q_3 a}{2} \right)}{N_3^2 \sin^2 \left(\frac{q_3 a}{2} \right)} \right] \quad (9.98)$$

where a is the lattice spacing, N_1, N_2, N_3 are the numbers of lattice sites along the three axes of the array, $N = N_1 N_2 N_3$ is the total number of scatterers and q_1, q_2, q_3 are the components of \mathbf{q} along the axes. At short wavelengths ($ka > \pi$), (9.98) has peaks when the Bragg scattering condition, $q_i a = 0, 2\pi, 4\pi, \dots$, is obeyed. This is the situation familiar in X-ray diffraction. But at long wavelengths only the peak at $q_i a = 0$ is relevant because $(q_i a)_{\max} = 2ka \ll 1$. In this limit $\mathcal{F}(\mathbf{q})$ is product of three factors of the form $[(\sin x_i)/x_i]^2$ with $x_i = N_i q_i a/2$. The scattering is thus confined to the region $q_i \leq 2\pi/N_i a$, corresponding to angles smaller than λ/L , where λ is the wavelength and L a typical overall dimension of the scattering array.

9.7 Perturbation Theory of Scattering, Rayleigh's Explanation of the Blue Sky,* Scattering by Gases and Liquids

(a) General Theory

If the medium through which an electromagnetic wave is passing is uniform in its properties, the wave propagates undisturbed and undeflected. If, however, there

* Although Rayleigh's name should undoubtedly be associated with the quantitative explanation of the blue sky, it is of some historical interest that Leonardo da Vinci understood the basic phenomenon around 1500. In particular, his experiments with the scattering of sunlight by wood smoke observed against a dark background (quoted as items 300–302, pp. 237 ff, in Vol. I of Jean Paul Richter, *The Literary Works of Leonardo da Vinci*, 3rd edition, Phaidon, London 1970) (also a Dover reprint entitled *The Notebooks of Leonardo da Vinci*, Vol. 1, pp. 161 ff.) anticipate by 350 years Tyndall's remarkably similar observations [J. Tyndall, *Phil. Trans. Roy. Soc.* **160**, 333 (1870)].

are spatial (or temporal) variations in the electromagnetic properties, the wave is scattered. Some of the energy is deviated from its original course. If the variations in the properties are small in magnitude, the scattering is slight and perturbative methods can be employed. We imagine a comparison situation corresponding to a uniform isotropic medium with dielectric constant ϵ_0 and permeability μ_0 . For the present ϵ_0 and μ_0 are assumed independent of frequency, although when harmonic time dependence is assumed this restriction can be removed in the obvious way. Through the action of some perturbing agent, the medium is supposed to have *small changes* in its response to applied fields, so that $\mathbf{D} \neq \epsilon_0 \mathbf{E}$, $\mathbf{B} \neq \mu_0 \mathbf{H}$, over certain regions of space. These departures may be functions of time and space variables. Beginning with the Maxwell equations in the absence of sources,

$$\begin{aligned}\nabla \cdot \mathbf{B} &= 0, & \nabla \times \mathbf{E} &= -\frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} \\ \nabla \cdot \mathbf{D} &= 0, & \nabla \times \mathbf{H} &= \frac{1}{c} \frac{\partial \mathbf{D}}{\partial t}\end{aligned}\tag{9.99}$$

it is a straightforward matter to arrive at a wave equation for \mathbf{D} ,

$$\nabla^2 \mathbf{D} - \frac{\mu_0 \epsilon_0}{c^2} \frac{\partial^2 \mathbf{D}}{\partial t^2} = -\nabla \times \nabla \times (\mathbf{D} - \epsilon_0 \mathbf{E}) + \frac{\epsilon_0}{c} \frac{\partial}{\partial t} \nabla \times (\mathbf{B} - \mu_0 \mathbf{H})\tag{9.100}$$

This equation is without approximation as yet, although later the right-hand side will be treated as small in some sense.*

If the right-hand side of (9.100) is taken as known, the equation is of the form of (6.54) with the retarded solution (6.69). In general, of course, the right-hand side is unknown and (6.69) must be regarded as an integral relation, rather than a solution. Nevertheless, such an integral formulation of the problem forms a fruitful starting point for approximations. It is convenient to specialize to harmonic time variation with frequency ω for the unperturbed fields and to assume that the departures $(\mathbf{D} - \epsilon_0 \mathbf{E})$ and $(\mathbf{B} - \mu_0 \mathbf{H})$ also have this time variation. This puts certain limitations on the kind of perturbed problem that can be described by the formalism, but prevents the discussion from becoming too involved. With a time dependence $e^{-i\omega t}$ understood, (9.100) becomes

$$(\nabla^2 + k^2) \mathbf{D} = -\nabla \times \nabla \times (\mathbf{D} - \epsilon_0 \mathbf{E}) - \frac{i\epsilon_0 \omega}{c} \nabla \times (\mathbf{B} - \mu_0 \mathbf{H})\tag{9.101}$$

where $k^2 = \mu_0 \epsilon_0 \omega^2 / c^2$, and μ_0 and ϵ_0 can be values specific to the frequency ω . The solution of the unperturbed problem, with the right-hand side of (9.101) set

* If prescribed sources $\rho(\mathbf{x}, t)$, $\mathbf{J}(\mathbf{x}, t)$ are present, (9.100) is modified by the addition to the left-hand side of

$$-4\pi \left[\nabla \rho + \frac{\mu_0 \epsilon_0}{c^2} \frac{\partial \mathbf{J}}{\partial t} \right]$$

equal to zero, will be denoted by $\mathbf{D}^{(0)}(\mathbf{x})$. A formal solution of (9.101) can be obtained from (6.67), if the right-hand side is taken as known. Thus

$$\mathbf{D} = \mathbf{D}^{(0)} + \frac{1}{4\pi} \int d^3x' \frac{e^{ik|\mathbf{x}-\mathbf{x}'|}}{|\mathbf{x}-\mathbf{x}'|} \left\{ \frac{\nabla' \times \nabla' \times (\mathbf{D} - \epsilon_0 \mathbf{E})}{c} + i\epsilon_0 \omega \nabla' \times (\mathbf{B} - \mu_0 \mathbf{H}) \right\} \quad (9.102)$$

If the physical situation is one of scattering, with the integrand in (9.102) confined to some finite region of space and $\mathbf{D}^{(0)}$ describing a wave incident in some direction, the field far away from the scattering region can be written as

$$\mathbf{D} \rightarrow \mathbf{D}^{(0)} + \mathbf{A}_{sc} \frac{e^{ikr}}{r} \quad (9.103)$$

where the *scattering amplitude* \mathbf{A}_{sc} is

$$\mathbf{A}_{sc} = \frac{1}{4\pi} \int d^3x' e^{-ik\mathbf{n} \cdot \mathbf{x}'} \left\{ \frac{\nabla' \times \nabla' \times (\mathbf{D} - \epsilon_0 \mathbf{E})}{c} + i\epsilon_0 \omega \nabla' \times (\mathbf{B} - \mu_0 \mathbf{H}) \right\} \quad (9.104)$$

The steps from (9.102) to (9.104) are the same as from (9.3) to (9.8) for the radiation fields. Some integrations by parts in (9.104) allows the scattering amplitude to be expressed as

$$\mathbf{A}_{sc} = \frac{k^2}{4\pi} \int d^3x e^{-ik\mathbf{n} \cdot \mathbf{x}} \left\{ \frac{[\mathbf{n} \times (\mathbf{D} - \epsilon_0 \mathbf{E})] \times \mathbf{n}}{-\frac{\epsilon_0 \omega}{kc} \mathbf{n} \times (\mathbf{B} - \mu_0 \mathbf{H})} \right\} \quad (9.105)$$

The vectorial structure of the integrand can be compared with the scattered dipole field (9.80). The polarization dependence of the contribution from $(\mathbf{D} - \epsilon_0 \mathbf{E})$ is that of an electric dipole, from $(\mathbf{B} - \mu_0 \mathbf{H})$ a magnetic dipole. In correspondence with (9.82) the differential scattering cross section is

$$\frac{d\sigma}{d\Omega} = \frac{|\boldsymbol{\epsilon}^* \cdot \mathbf{A}_{sc}|^2}{|\mathbf{D}^{(0)}|^2} \quad (9.106)$$

where $\boldsymbol{\epsilon}$ is the polarization vector of the scattered radiation.

Equations (9.102), (9.105), and (9.106) provide a formal solution to the scattering problem posed at the beginning of the section. The scattering amplitude \mathbf{A}_{sc} is not known, of course, until the fields are known at least approximately. But from (9.102) a systematic scheme of successive approximations can be developed in the same way as the Born approximation series of quantum-mechanical scattering. If the integrand in (9.102) can be approximated to first order, then (9.102) provides a first approximation for \mathbf{D} , beyond $\mathbf{D}^{(0)}$. This approximation to \mathbf{D} can be used to give a second approximation for the integrand, and an improved \mathbf{D} can be determined, and so on. Questions of convergence of the series, etc. have been much studied in the quantum-mechanical context. The series is not very useful unless the first few iterations converge rapidly.

(b) *Born Approximation*

We will be content with the lowest order approximation for the scattering amplitude. This is called the *first Born approximation* or just the Born approximation in quantum theory and was actually developed in the present context by Lord Rayleigh in 1881. Furthermore, we shall restrict our subsequent discussion to the simple example of spatial variations in the linear response of the medium. Thus we assume that the connections between \mathbf{D} and \mathbf{E} and \mathbf{B} and \mathbf{H} are

$$\begin{aligned}\mathbf{D}(\mathbf{x}) &= [\epsilon_0 + \delta\epsilon(\mathbf{x})]\mathbf{E}(\mathbf{x}) \\ \mathbf{B}(\mathbf{x}) &= [\mu_0 + \delta\mu(\mathbf{x})]\mathbf{H}(\mathbf{x})\end{aligned}\quad (9.107)$$

where $\delta\epsilon(\mathbf{x})$ and $\delta\mu(\mathbf{x})$ are small in magnitude compared with ϵ_0 and μ_0 . The differences appearing in (9.102) and (9.105) are proportional to $\delta\epsilon$ and $\delta\mu$. To lowest order then, the fields in these differences can be approximated by the unperturbed fields:

$$\begin{aligned}\mathbf{D} - \epsilon_0\mathbf{E} &\approx \frac{\delta\epsilon(\mathbf{x})}{\epsilon_0} \mathbf{D}^{(0)}(\mathbf{x}) \\ \mathbf{B} - \mu_0\mathbf{H} &\approx \frac{\delta\mu(\mathbf{x})}{\mu_0} \mathbf{B}^{(0)}(\mathbf{x})\end{aligned}\quad (9.108)$$

If the unperturbed fields are those of a plane wave propagating in a direction \mathbf{n}_0 , so that $\mathbf{D}^{(0)}$ and $\mathbf{B}^{(0)}$ are

$$\begin{aligned}\mathbf{D}^{(0)}(\mathbf{x}) &= \epsilon_0 D_0 e^{ik\mathbf{n}_0 \cdot \mathbf{x}} \\ \mathbf{B}^{(0)}(\mathbf{x}) &= \sqrt{\frac{\mu_0}{\epsilon_0}} \mathbf{n}_0 \times \mathbf{D}^{(0)}(\mathbf{x})\end{aligned}$$

the scalar product of the scattering amplitude (9.105) and ϵ^* , divided by D_0 , is

$$\frac{\epsilon^* \cdot \mathbf{A}_{sc}^{(1)}}{D_0} = \frac{k^2}{4\pi} \int d^3x e^{i\mathbf{q} \cdot \mathbf{x}} \left\{ \epsilon^* \cdot \epsilon_0 \frac{\delta\epsilon(\mathbf{x})}{\epsilon_0} + (\mathbf{n} \times \epsilon^*) \cdot (\mathbf{n}_0 \times \epsilon_0) \frac{\delta\mu(\mathbf{x})}{\mu_0} \right\} \quad (9.109)$$

where $\mathbf{q} = k(\mathbf{n}_0 - \mathbf{n})$ is the difference of the incident and scattered wave vectors. The absolute square of (9.109) gives the differential scattering cross section (9.106).

If the wavelength is large compared with the spatial extent of $\delta\epsilon$ and $\delta\mu$, the exponential in (9.109) can be set equal to unity. The amplitude is then a dipole approximation analogous to the previous section, with the dipole frequency dependence and angular distribution. To establish contact with the results already obtained, suppose that the scattering region is a uniform dielectric sphere of radius a in vacuum. Then $\epsilon_0 = 1$ and $\delta\epsilon$ is constant inside a spherical volume of radius a and vanishes outside. The integral in (9.109) can be

performed for arbitrary $|\mathbf{q}|$, with the result,

$$\frac{\boldsymbol{\epsilon}^* \cdot \mathbf{A}_{sc}}{D_0} = k^2 \delta\epsilon(\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0) \left[\frac{\sin qa - qa \cos qa}{q^3} \right]$$

In the limit $q \rightarrow 0$ the square bracket approaches $a^3/3$. Thus, at very low frequencies or in the forward direction at all frequencies, the Born approximation to the differential cross section for scattering by a dielectric sphere of radius a is

$$\lim_{q \rightarrow 0} \left(\frac{d\sigma}{d\Omega} \right)_{\text{Born}} = k^4 a^6 \left| \frac{\delta\epsilon}{3} \right|^2 |\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0|^2 \quad (9.110)$$

Comparison with (9.84) shows that the Born approximation and the exact low frequency result have the expected relationship.

(c) Blue Sky—Elementary Argument

The scattering of light by gases, first treated quantitatively by Lord Rayleigh in his celebrated work on the sunset and blue sky,* can be discussed in the present framework. Since the magnetic moments of most gas molecules are negligible compared to the electric dipole moments, the scattering is purely electric dipole in character. In the previous section we have discussed the angular distribution and polarization of the individual scatterings (see Figure 9.6). We therefore confine our attention to the total scattering cross section and the attenuation of the incident beam. The treatment is in two parts. The first, elementary argument is adequate for a dilute ideal gas, where the molecules are truly randomly distributed in space relative to each other. The second, based on density fluctuations in the gas, is of more general validity.

If the individual molecules, located at \mathbf{x}_j , are assumed to possess dipole moments $\mathbf{p}_j = \gamma_{\text{mol}} \mathbf{E}(\mathbf{x}_j)$, the effective variation in dielectric constant $\delta\epsilon(\mathbf{x})$ in (9.109) can be written as

$$\delta\epsilon(\mathbf{x}) = 4\pi \sum_j \gamma_{\text{mol}} \delta_{\mathbf{x}}(\mathbf{x} - \mathbf{x}_j) \quad (9.111)$$

The differential scattering cross section obtained from (9.109) and (9.106) is

$$\frac{d\sigma}{d\Omega} = k^4 |\gamma_{\text{mol}}|^2 \cdot |\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0|^2 \mathcal{F}(\mathbf{q})$$

where $\mathcal{F}(\mathbf{q})$ is given by (9.97). For a random distribution of scattering centers the structure factor reduces to an incoherent sum, and the cross section is just that for one molecule, times the number of molecules. For a dilute gas the molecular

* Lord Rayleigh, *Phil. Mag.* **XLI**, 107, 274, (1871); *Ibid* **XLVII**, 375 (1899); reprinted in his *Scientific Papers*, Vol. I, p. 87, and Vol. 4, p. 397. Rayleigh's papers are well worth reading as examples of a masterful physicist at work.

polarizability is related to the dielectric constant by $\epsilon \approx 1 + 4\pi N\gamma_{\text{mol}}$, where N is the number of molecules per unit volume. The total scattering cross section *per molecule* of the gas is thus

$$\sigma \approx \frac{k^4}{6\pi N^2} |\epsilon - 1|^2 \approx \frac{2k^4}{3\pi N^2} |n - 1|^2 \quad (9.112)$$

where the last form is written in terms of the index of refraction n , assuming $|n - 1| \ll 1$. The cross section (9.112) represents the power scattered per molecule for a unit incident energy flux. In traversing a thickness dx of the gas, the fractional loss of flux is $N\sigma dx$. The incident beam thus has an intensity $I(x) = I_0 e^{-\alpha x}$, where α is the *absorption or attenuation coefficient* (also called the *extinction coefficient*) of (7.53) and is given by

$$\alpha = N\sigma \approx \frac{2k^4}{3\pi N} |n - 1|^2 \quad (9.113)$$

These results, (9.112) and (9.113), describe what is known as *Rayleigh scattering*, the incoherent scattering by gas molecules or other randomly distributed dipole scatterers, each scattering according to Rayleigh's ω^4 law.

Rayleigh's derivation of (9.113) was in the context of scattering of light by the atmosphere. Evidently the k^4 dependence means that in the visible spectrum the red is scattered least and the violet most. Light received away from the direction of the incident beam is more heavily weighted in high frequency (blue) components than the spectral distribution of the incident beam, while the transmitted beam becomes increasingly red in its spectral composition, as well as diminishing in overall intensity. The blueness of the sky, the redness of the sunset, the waning of the winter sun, and the ease of sunburning at midday in summer are all consequences of Rayleigh scattering in the atmosphere. The index of refraction of air in the visible region (4100–6500 Å) and at N.T.P. is $(n - 1) \approx 2.78 \times 10^{-4}$. With $N = 2.69 \times 10^{19}$ molecules/cm³, typical values of the attenuation length $\Lambda = \alpha^{-1}$ are $\Lambda = 30, 77, 188$ km for violet (4100 Å), green (5200 Å), red (6500 Å) light, respectively. With an isothermal model of the atmosphere in which the density varies exponentially with height, the following intensities at the earth's surface *relative* to those incident on the top of the atmosphere at each wavelength can be estimated for the sun at zenith and sunrise-sunset:

Color	Zenith	Sunrise-Sunset
Red (6500 Å)	0.96	0.21
Green (5200 Å)	0.90	0.024
Violet (4100 Å)	0.76	0.000065

These numbers show strikingly the shift to the red of the surviving sunlight at sunrise and sunset.

Fig. 9.8 Power spectrum of solar radiation (in watts per square meter per electron volt) as a function of photon energy (in electron volts). Curve A is the incident spectrum above the atmosphere. Curve B is a typical sea-level spectrum with the sun at the zenith. The absorption bands below 2 eV are chiefly from water vapor and vary from site to site and day to day. The dashed curves give the expected sea-level spectrum at zenith and at sunrise-sunset if the only attenuation is from Rayleigh scattering by a dry, clean atmosphere.

The actual situation is illustrated in Fig. 9.8. The curve A shows the power spectrum of solar radiation incident on the earth from outside as a function of photon energy. Curve B is a typical spectrum at sea level with the sun directly overhead.* The upper dashed curve is the result expected from curve A if the only attenuation is Rayleigh scattering by a dry, clean, isothermal, exponential atmosphere. In reality the attenuation is greater, mainly because of the presence of water vapor, which has strong absorption bands in the infrared, and ozone,

* The data in Fig. 9.8 were derived from W. E. Forsythe, *Smithsonian Physical Tables* 9th revised edition, Smithsonian Institution, Washington, D.C. (1954), Tables 813 and 815, and from K. Ya. Kondratyev, *Radiation in the Atmosphere*, Academic, New York (1969), Chapter 5.

which causes absorption of the ultraviolet, as well as other molecular species and dust. The lower dashed curve indicates roughly the sunrise-sunset spectrum at sea level. Astronauts orbiting the earth see even redder sunsets because the atmospheric path length is doubled.

Detailed observations on the polarization of the scattered light from the sky have been reported.* Just as with the attenuation, the reality departs somewhat from the ideal of a dry, clean atmosphere of low density. At 90° the polarization is a function of wavelength and reaches a maximum of approximately 75 per cent at 5500 \AA . It is estimated to be less than 100 per cent because of multiple scattering (6%), molecular anisotropy (6%), ground reflection (5%, and especially important in the green when green vegetation is present), and aerosols (8%).

The formula (9.113) for the extinction coefficient is remarkable in its possession of the factor N^{-1} as well as macroscopic quantities such as the index of refraction. If there were no atomicity ($N \rightarrow \infty$), there would be no attenuation. Conversely, the observed attenuation can be used to determine N . This point was urged particularly on Rayleigh by Maxwell in private correspondence. If the properties of the atmosphere are assumed to be well enough known, the relative intensity of the light from a definite star as a function of altitude can be used to determine N . Early estimates were made in this way and agree with the results of more conventional methods.

(d) Density Fluctuations, Critical Opalescence

An alternative and more general approach to the scattering and attenuation of light in gases and liquids is to consider fluctuations in the density and so the index of refraction. The volume V of fluid is imagined to be divided into cells small compared to a wavelength, but each containing very many molecules. Each cell has volume v with an average number $N_v = vN$ of molecules inside. The actual number of molecules fluctuates around N_v in a manner that depends on the properties of the gas or liquid. Let the departure from the mean of the number of molecules in the j th cell be ΔN_j . The variation in index of refraction $\delta\epsilon$ for the j th cell is

$$\delta\epsilon_j = \frac{\partial\epsilon}{\partial N} \cdot \frac{\Delta N_j}{v}$$

From the Clausius-Mossotti relation (4.70), this can be written

$$\delta\epsilon_j = \frac{(\epsilon - 1)(\epsilon + 2)}{3Nv} \Delta N_j \quad (9.114)$$

With this expression for $\delta\epsilon$ for the j th cell, the integral (9.109), now a sum over

* T. Gehrels, *J. Opt. Soc. Am.* **52**, 1164 (1962).

cells, becomes

$$\frac{\boldsymbol{\epsilon}^* \cdot \mathbf{A}_{sc}^{(1)}}{D_0} = \boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0 \frac{k^2(\epsilon-1)(\epsilon+2)}{12\pi N\epsilon} \sum_j \Delta N_j e^{i\mathbf{q} \cdot \mathbf{r}_j} \quad (9.115)$$

In forming the absolute square of (9.115) a structure factor similar to (9.97) will occur. If it is assumed that the correlation of fluctuations in different cells (caused indirectly by the intermolecular forces) only extends over a distance small compared to a wavelength, the exponential in (9.115) can be put equal to unity. Then the extinction coefficient α , given by

$$\alpha = \frac{1}{V} \int \left| \frac{\boldsymbol{\epsilon}^* \cdot \mathbf{A}_{sc}^{(1)}}{D_0} \right|^2 d\Omega$$

is

$$\alpha = \frac{(\omega/c)^4}{6\pi N} \left| \frac{(\epsilon-1)(\epsilon+2)}{3} \right|^2 \cdot \frac{\Delta N_V^2}{NV} \quad (9.116)$$

where ΔN_V^2 is the mean square number fluctuation in the volume V , defined by

$$\Delta N_V^2 = \sum_{jj'} \Delta N_j \Delta N_{j'}$$

the sum being over all the cells in the volume V . With the use of statistical mechanics the quantity ΔN_V^2 can be expressed in terms of the *isothermal compressibility* β_T of the medium:

$$\frac{\Delta N_V^2}{NV} = NkT\beta_T, \quad \beta_T = -\frac{1}{V} \left(\frac{\partial V}{\partial P} \right)_T \quad (9.117)$$

The attenuation coefficient (9.116) then becomes

$$\alpha = \frac{1}{6\pi N} \left(\frac{\omega}{c} \right)^4 \left| \frac{(\epsilon-1)(\epsilon+2)}{3} \right|^2 \cdot NkT\beta_T \quad (9.118)$$

This particular expression, first obtained by Einstein in 1910, is called the Einstein-Smoluchowski formula. For a dilute ideal gas, with $|\epsilon-1| \ll 1$ and $NkT\beta_T = 1$, it reduces to the Rayleigh result (9.113). As the critical point is approached, β_T becomes very large (infinite exactly at the critical point). The scattering and attenuation thus becomes large there. This is the phenomenon known as *critical opalescence*. The large scattering is directly related to the large fluctuations in density near the critical point, as stressed originally by Smoluchowski (1904). Very near the critical point our treatment fails because the correlation length for the density fluctuations becomes greater than a wavelength, as first pointed out by Ornstein and Zernicke (1914). The correct treatment involves the Fourier transform of the radial distribution function of density. References to the early literature can be found in the book by *Fabelinskii* who discusses in detail the application of light scattering to the study

of critical point phenomena and second order phase transitions. A nice discussion of the occurrence of the radial density distribution is given in Chapter V, Section 6 of *Rosenfeld*.

9.8 Scalar Diffraction Theory

Although scattering and diffraction are not logically separate, the treatments tend to be separated, with diffraction being associated with departures from geometrical optics caused by the finite wavelength of the waves. Thus diffraction traditionally involves apertures or obstacles whose dimensions are large compared to a wavelength. To lowest approximation the interaction of electromagnetic waves is described by ray tracing (geometrical optics). The next approximation involves the diffraction of the waves around the obstacles or through the apertures with a consequent spreading of the waves. Simple arguments based on Fourier transforms show that the angles of deflection of the waves are confined to the region $\theta \leq \lambda/d$ where λ is the wavelength and d is a linear dimension of the aperture or obstacle. The various approximations to be discussed below all work best for $\lambda/d \ll 1$, and fail badly for $\lambda \sim d$ or $\lambda > d$.

The earliest work on diffraction is associated with the names of Huygens, Young, and Fresnel. The first systematic attempt to derive the Fresnel theory from first principles was made by G. Kirchhoff (1882). Kirchhoff's theory, despite its mathematical inconsistency and its physical deficiencies, works remarkably well in the optical domain and has been the basis of most of the work on diffraction. We first derive the basic Kirchhoff integral and its operative approximations, then comment on its mathematical difficulties, and finally describe the modifications of Rayleigh and Sommerfeld that remove the mathematical inconsistencies.

The customary geometry in diffraction involves two spatial regions I and II, separated by a boundary surface S_1 , as shown in Fig. 9.9. The surface S_2 is

Fig. 9.9 Possible diffraction geometries. Region I contains the sources of radiation. Region II is the diffraction region, where the fields satisfy the radiation condition. The right-hand figure is also indicative of scattering, with a finite scatterer in region I instead of an active source, and the surface S_1 an arbitrary mathematical surface enclosing the scatterer rather than a material screen with apertures.

generally taken to be “at infinity,” that is, remote from the region of interest. Sources in region I generate fields that propagate outwards. The surface S_1 is supposed to be made up of “opaque” portions (the boundary conditions are discussed below) and apertures. The surface S_1 interacts with the fields generated in region I, reflecting some of the energy, absorbing some of it, and allowing some of the fields, modified by their interaction, to pass into region II. The angular distribution of the fields in region II, the diffraction region, is called the *diffraction pattern*. It is the diffracted fields in region II that we wish to express in terms of the fields of the sources and their interaction with the screen and apertures on S_1 , or more precisely, in terms of the fields on the surface S_1 . It should be obvious that the geometry and mode of description is equally applicable to scattering, with the sources in region I replaced by a scatterer (thought of as a source being driven by the incident wave).

Kirchhoff's method uses Green's theorem (1.35) to express a scalar field (a component of \mathbf{E} or \mathbf{B}) inside a closed volume V in terms of the values of the field and its normal derivative on the boundary surface S . Let the scalar field be $\psi(\mathbf{x}, t)$, and let it have harmonic time dependence, $e^{-i\omega t}$. The field ψ is assumed to satisfy the scalar Helmholtz wave equation,

$$(\nabla^2 + k^2)\psi(\mathbf{x}) = 0 \quad (9.119)$$

inside V . We introduce a Green function for the Helmholtz wave equation $G(\mathbf{x}, \mathbf{x}')$, defined by

$$(\nabla^2 + k^2)G(\mathbf{x}, \mathbf{x}') = -\delta(\mathbf{x} - \mathbf{x}') \quad (9.120)$$

In Green's theorem (1.35), we put $\phi = G$, $\psi = \psi$, make use of the wave equations (9.119) and (9.120), and obtain, in analogy to (1.36) on p. 41,

$$\psi(\mathbf{x}) = \oint_S [\psi(\mathbf{x}')\mathbf{n}' \cdot \nabla' G(\mathbf{x}, \mathbf{x}') - G(\mathbf{x}, \mathbf{x}')\mathbf{n}' \cdot \nabla' \psi(\mathbf{x}')] da' \quad (9.121)$$

where \mathbf{n}' is an *inwardly* directed normal to the surface S . Equation (9.121) holds if \mathbf{x} is inside V ; if it is not, the left-hand side vanishes.

The Kirchhoff diffraction integral is obtained from (9.121) by taking G to be the infinite space Green function describing outgoing waves,

$$G(\mathbf{x}, \mathbf{x}') = \frac{e^{ikR}}{4\pi R} \quad (9.122)$$

where $\mathbf{R} = \mathbf{x} - \mathbf{x}'$. With this Green function, (9.121) becomes

$$\psi(\mathbf{x}) = -\frac{1}{4\pi} \oint_S \frac{e^{ikR}}{R} \mathbf{n}' \cdot \left[\nabla' \psi + ik \left(1 + \frac{i}{kR} \right) \frac{\mathbf{R}}{R} \psi \right] da' \quad (9.123)$$

This is almost the Kirchhoff integral. To adapt the mathematics to the diffraction context we consider the volume V to be that of region II in Fig. 9.9 and the surface S to consist of $S_1 + S_2$. The integral over S is thus divided into two parts,

one over the screen and its apertures (S_1), the other over a surface “at infinity” (S_2). Since the fields in region II are assumed to be transmitted through S_1 , they are outgoing waves in the neighborhood of S_2 . The fields and hence $\psi(\mathbf{x})$ will satisfy a *radiation condition*,

$$\psi \rightarrow f(\theta, \phi) \frac{e^{ikr}}{r}, \quad \frac{1}{\psi} \frac{\partial \psi}{\partial r} \rightarrow \left(ik - \frac{1}{r} \right) \quad (9.124)$$

With this condition on ψ at S_2 it is easily seen that the contribution from S_2 in (9.123) vanishes at least as the inverse of the radius of the hemisphere or sphere as the radius goes to infinity. There remains the integral over S_1 . The *Kirchhoff integral* formula reads

$$\psi(\mathbf{x}) = -\frac{1}{4\pi} \int_{S_1} \frac{e^{ikR}}{R} \mathbf{n}' \cdot \left[\nabla' \psi + ik \left(1 + \frac{i}{kR} \right) \frac{\mathbf{R}}{R} \psi \right] da' \quad (9.125)$$

with the integration only over the surface S_1 of the diffracting “screen.”

In order to apply (9.125) it is necessary to know the values of ψ and $\partial\psi/\partial n$ on the surface S_1 . Unless the problem has been solved by other means, these values are not known. Kirchhoff’s approach was to approximate the values of ψ and $\partial\psi/\partial n$ on S_1 in order to calculate an approximation to the diffracted wave. The *Kirchhoff approximation* consists of the assumptions:

1. ψ and $\partial\psi/\partial n$ vanish everywhere on S_1 except in the openings.
2. The values of ψ and $\partial\psi/\partial n$ in the openings are equal to the values of the incident wave in the absence of any screen or obstacles.

The standard diffraction calculations of classical optics are all based on the Kirchhoff approximation. It is obvious that the recipe can have only limited validity. There is, in fact, a serious mathematical inconsistency in the assumptions of Kirchhoff. It can be shown for the Helmholtz wave equation (9.119), as well as for the Laplace equation, that if ψ and $\partial\psi/\partial n$ are both zero on any finite surface, then $\psi = 0$ everywhere. Thus the only mathematically correct consequence of the first Kirchhoff assumption is that the diffracted field vanishes everywhere. This is, of course, inconsistent with the second assumption. Furthermore, (9.125) does not yield on S_1 the assumed values of ψ and $\partial\psi/\partial n$.

The mathematical inconsistencies in the Kirchhoff approximation can be removed by the choice of a proper Green function in (9.121). Just as in Section 1.10, a Green function appropriate to Dirichlet or Neumann boundary conditions can be constructed. If ψ is known or approximated on the surface S_1 , a Dirichlet Green function $G_D(\mathbf{x}, \mathbf{x}')$, satisfying

$$G_D(\mathbf{x}, \mathbf{x}') = 0 \quad \text{for } \mathbf{x}' \text{ on } S \quad (9.126)$$

is required. Then a *generalized Kirchhoff integral*, equivalent to (9.125), is

$$\psi(\mathbf{x}) = \int_{S_1} \psi(\mathbf{x}') \frac{\partial G_D}{\partial n'}(\mathbf{x}, \mathbf{x}') da' \quad (9.127)$$

Fig. 9.10 Diffraction geometry for a point source at P' , a plane screen with apertures, and an observation point at P . The distances from the element of area da' in the aperture to the points P and P' are r and r' , respectively. The angles θ and θ' are those between \mathbf{r} and \mathbf{n} , and \mathbf{r}' and $-\mathbf{n}$, respectively.

and a *consistent* approximation is that $\psi = 0$ on S_1 except in the openings and ψ is equal to the incident wave in the openings. If the normal derivative of ψ is to be approximated, a Neumann Green function $G_N(\mathbf{x}, \mathbf{x}')$, satisfying

$$\frac{\partial G_N}{\partial n'}(\mathbf{x}, \mathbf{x}') = 0 \quad \text{for } \mathbf{x}' \text{ on } S \quad (9.128)$$

is employed. Then the generalized Kirchhoff integral for Neumann boundary conditions reads

$$\psi(\mathbf{x}) = - \int_{S_1} \frac{\partial \psi}{\partial n'}(\mathbf{x}') G_N(\mathbf{x}, \mathbf{x}') da' \quad (9.129)$$

Again a consistent approximation scheme can be formulated.

For the important special circumstance in which the surface S_1 is an infinite plane screen at $z=0$, as shown in Fig. 9.10, the method of images can be used to give the Dirichlet and Neumann Green functions explicit form:

$$G_{D,N}(\mathbf{x}, \mathbf{x}') = \frac{1}{4\pi} \left(\frac{e^{ikR}}{R} \mp \frac{e^{ikR'}}{R'} \right) \quad (9.130)$$

where $\mathbf{R} = \mathbf{x} - \mathbf{x}'$, and $\mathbf{R}' = \mathbf{x} - \mathbf{x}''$, \mathbf{x}'' being the mirror image of \mathbf{x}' . Explicitly we have

$$R = [(x-x')^2 + (y-y')^2 + (z-z')^2]^{1/2}$$

$$R' = [(x-x')^2 + (y-y')^2 + (z+z')^2]^{1/2}$$

The generalized Kirchhoff integral (9.127) (ψ approximated on S_1) then takes

the form,

$$\psi(\mathbf{x}) = \frac{k}{2\pi i} \int_{S_1} \frac{e^{ikR}}{R} \left(1 + \frac{i}{kR}\right) \frac{\mathbf{n}' \cdot \mathbf{R}}{R} \psi(\mathbf{x}') da' \quad (9.131)$$

An analogous expression can be written for (9.129), both results attributable to the ubiquitous Rayleigh.*

Comparison of (9.131) with (9.125) shows that (9.131) can be obtained from (9.125) by omitting the first term in the square brackets and doubling the second term. The Neumann result (9.129) specialized to a plane screen is equivalent, on the other hand, to doubling the first term and omitting the second. It might thus appear that the three approximate formulas for the diffracted field are quite different and will lead to very different results. In the domain where they have any reasonable validity they yield, in fact, very similar results. This can be understood by specializing the diffraction problem to a *point source* at position P' on one side of a plane screen and an observation point P on the other side, as shown in Fig. 9.10. The amplitude of the point source is taken to be spherically symmetric and equal to $e^{ikr'}/r'$. Both P and P' are assumed to be many wavelengths away from the screen. With the Kirchhoff approximation in (9.125) and equivalent assumptions in (9.131) and its Neumann boundary condition counterpart, the diffracted fields for all three approximations can be written in the common form,

$$\psi(P) = \frac{k}{2\pi i} \int_{\text{Apertures}} \frac{e^{ikr}}{r} \frac{e^{ikr'}}{r'} \mathcal{O}(\theta, \theta') da' \quad (9.132)$$

where the *obliquity factor* $\mathcal{O}(\theta, \theta')$ is the only point of difference. These factors are

$$\mathcal{O}(\theta, \theta') = \begin{cases} \cos \theta & (\psi \text{ approximated on } S_1) \\ \cos \theta' & \left(\frac{\partial \psi}{\partial n} \text{ approximated on } S_1\right) \\ \frac{1}{2}(\cos \theta + \cos \theta') & (\text{Kirchhoff approximation}) \end{cases}$$

where the angles are defined in Fig. 9.10. For apertures whose dimensions are large compared to a wavelength the diffracted intensity is confined to a narrow range of angles and is governed almost entirely by the interferences between the two exponential factors in (9.132). If the source point P' and the observation point P are far from the screen in terms of the *aperture* dimensions, the obliquity factor in (9.132) can be treated as a constant. Then the relative amplitudes of the different diffracted fields will be the same. For normal incidence all obliquity

* Equation (9.131) was also used by Sommerfeld in his early discussions of diffraction. See Sommerfeld, *Optics*, p. 197 ff.

factors are approximately unity where there is appreciable diffracted intensity. In this case even the absolute magnitudes are the same.

The above discussion explains to some extent why the mathematically inconsistent Kirchhoff approximation has any success at all. The use of Dirichlet or Neumann Green functions gives a better logical structure, but provides little practical improvement without further elaboration of the physics. An important deficiency of the discussion so far is its scalar nature. Electromagnetic fields have vector character. This must be incorporated into any realistic treatment, even if approximate. In the next section we proceed with the task of obtaining the vector equivalent of the Kirchhoff or generalized Kirchhoff integral for a plane screen.

9.9 Vector Equivalents of Kirchhoff Integral

The Kirchhoff integral formula (9.125) is an *exact* formal relation expressing the scattered or diffracted scalar field $\psi(\mathbf{x})$ in region II of Fig. 9.9 in terms of an integral of ψ and $\partial\psi/\partial n$ over the finite surface S_1 . Corresponding vectorial relations, expressing \mathbf{E} and \mathbf{B} in terms of surface integrals, are useful as a basis for a vectorial Kirchhoff approximation for diffraction (Section 9.10) and scattering (Section 9.13), and also for formal developments such as the proof of the optical theorem (Section 9.14).

To derive a Kirchhoff integral for the electric field, we begin with (9.121) for each rectangular component of \mathbf{E} and write the obvious vectorial equivalent,

$$\mathbf{E}(\mathbf{x}) = \oint_S [\mathbf{E}(\mathbf{n}' \cdot \nabla' G) - G(\mathbf{n}' \cdot \nabla') \mathbf{E}] da' \quad (9.133)$$

provided the point \mathbf{x} is inside the volume V bounded by the surface S . Here, as in (9.121), the unit normal \mathbf{n}' is directed *into* the volume V . Eventually we will specify G to be the infinite-space Green function, (9.122), but for the present we leave it as any solution of (9.120). Because we wish to use certain theorems of vector calculus that apply to well-behaved functions, while G is singular at $\mathbf{x}' = \mathbf{x}$, we must exercise some care. We imagine that the surface S consists of an outer surface S' and a infinitesimally small inner surface S'' surrounding the point $\mathbf{x}' = \mathbf{x}$. Then, from Green's theorem, the left-hand side of (9.133) vanishes. Of course, evaluation of the integral over the inner surface S'' , in the limit as it shrinks to zero around $\mathbf{x}' = \mathbf{x}$, gives $-\mathbf{E}(\mathbf{x})$. Thus (9.133) is restored in practice, but by excluding the point $\mathbf{x}' = \mathbf{x}$ from the volume V the necessary good mathematical behavior is assured. With this understanding concerning the surface S , we rewrite (9.133) in the form,

$$0 = \oint_S [2\mathbf{E}(\mathbf{n}' \cdot \nabla' G) - \mathbf{n}' \cdot \nabla' (G\mathbf{E})] da'$$

The divergence theorem can be used to convert the second term into a volume integral, thus yielding

$$0 = \oint_S 2\mathbf{E}(\mathbf{n}' \cdot \nabla' G) da' + \int_V \nabla'^2 (G\mathbf{E}) d^3x'$$

With the use of $\nabla^2 \mathbf{A} = \nabla(\nabla \cdot \mathbf{A}) - \nabla \times (\nabla \times \mathbf{A})$ for any vector field \mathbf{A} , and the vector calculus theorems,

$$\begin{aligned} \int_V \nabla \phi d^3x &= \oint_S \mathbf{n} \phi da \\ \int_V \nabla \times \mathbf{A} d^3x &= \oint_S (\mathbf{n} \times \mathbf{A}) da \end{aligned} \quad (9.134)$$

where ϕ and \mathbf{A} are any well-behaved scalar and vector functions (and \mathbf{n} is the *outward* normal), we can express the volume integral again as a surface integral. We thus obtain

$$0 = \oint_S [2\mathbf{E}(\mathbf{n}' \cdot \nabla' G) - \mathbf{n}'(\nabla' \cdot (G\mathbf{E})) + \mathbf{n}' \times (\nabla' \times (G\mathbf{E}))] da'$$

Carrying out the indicated differentiation of the product $G\mathbf{E}$, and making use of the Maxwell equations, $\nabla' \cdot \mathbf{E} = 0$, $\nabla' \times \mathbf{E} = ik\mathbf{B}$, we find

$$0 = \oint_S [ik(\mathbf{n}' \times \mathbf{B})G + 2\mathbf{E}(\mathbf{n}' \cdot \nabla' G) - \mathbf{n}'(\mathbf{E} \cdot \nabla' G) + \mathbf{n}' \times (\nabla' G \times \mathbf{E})] da'$$

Expansion of the triple cross product and a rearrangement of terms yields the final result,

$$\mathbf{E}(\mathbf{x}) = \oint_S [ik(\mathbf{n}' \times \mathbf{B})G + (\mathbf{n}' \times \mathbf{E}) \times \nabla' G + (\mathbf{n}' \cdot \mathbf{E}) \nabla' G] da' \quad (9.135)$$

where now the volume V bounded by the surface S contains the point $\mathbf{x}' = \mathbf{x}$. An analogous expression for \mathbf{B} can be obtained from (9.135) by means of the substitutions, $\mathbf{E} \rightarrow \mathbf{B}$ and $\mathbf{B} \rightarrow -\mathbf{E}$.

Equation (9.135) is the vectorial equivalent of the scalar formula (9.121). To obtain the analogue of the Kirchhoff integral (9.125), we consider the geometry of Fig. 9.9 and let the surface S be made up of a finite surface S_1 surrounding the sources or scatterer and a surface S_2 "at infinity." There is no loss of generality in taking S_2 to be a spherical shell of radius $r_0 \rightarrow \infty$. The integral in (9.135) can be written as the sum of two integrals, one over S_1 and one over S_2 . On the surface S_2 the Green function (9.122) is given, for large enough r_0 , by

$$G \rightarrow \frac{e^{ikr'}}{4\pi r'} e^{ik\mathbf{n}' \cdot \mathbf{x}}$$

and its gradient by

$$\nabla' G \rightarrow -ik\mathbf{n}' G$$

Then the contribution from S_2 to (9.135) is

$$\oint_{S_2} = ik \oint_{S_2} [\mathbf{n}' \times \mathbf{B} - (\mathbf{n}' \times \mathbf{E}) \times \mathbf{n}' - \mathbf{n}'(\mathbf{n}' \cdot \mathbf{E})] G da'$$

or

$$\oint_{S_2} = ik \oint_{S_2} [(\mathbf{n}' \times \mathbf{B}) - \mathbf{E}] G da'$$

The fields in region II are diffracted or scattered fields and so satisfy the condition of outgoing waves in the neighborhood of S_2 . In particular, the fields \mathbf{E} and \mathbf{B} are mutually perpendicular and transverse to the radius vector. Thus, on S_2 , $\mathbf{E} = \mathbf{n}' \times \mathbf{B} + O(1/r_0^2)$. This shows that

$$\oint_{S_2} \rightarrow 0 \left(\frac{1}{r_0} \right)$$

and the contribution from the integral over S_2 vanishes as $r_0 \rightarrow \infty$. For the geometry of Fig. 9.9, then, with S_2 at infinity, the electric field in region II satisfies the *vector Kirchhoff integral relation*,

$$\mathbf{E}(\mathbf{x}) = \oint_{S_1} [ik(\mathbf{n}' \times \mathbf{B})G + (\mathbf{n}' \times \mathbf{E}) \times \nabla' G + (\mathbf{n}' \cdot \mathbf{E}) \nabla' G] da' \quad (9.136)$$

where G is given by (9.122) and the integral is only over the finite surface S_1 .

It is useful to specialize (9.136) to a scattering situation and to exhibit a formal expression for the scattering amplitude as an integral of the scattered fields over S_1 . The geometry is shown in Fig. 9.11. On both sides of (9.136) the fields are taken to be the scattered fields (\mathbf{E}_s , \mathbf{B}_s), that is, the total fields (\mathbf{E} , \mathbf{B}) minus the incident wave (\mathbf{E}_i , \mathbf{B}_i). If the observation point P is far from the scatterer, then the Green function and the scattered electric field take on their asymptotic forms,

$$G(\mathbf{x}, \mathbf{x}') \rightarrow \frac{1}{4\pi} \frac{e^{ikr}}{r} e^{-i\mathbf{k} \cdot \mathbf{x}'}$$

$$\mathbf{E}_s(\mathbf{x}) \rightarrow \frac{e^{ikr}}{r} \mathbf{F}(\mathbf{k}, \mathbf{k}_0)$$

where \mathbf{k} is the wave vector in the direction of observation, \mathbf{k}_0 is the incident wave vector, and $\mathbf{F}(\mathbf{k}, \mathbf{k}_0)$ is the (unnormalized) vectorial scattering amplitude. In this limit, $\nabla' G = -i\mathbf{k}G$. Thus (9.136) can be written as an *integral expression for the scattering amplitude* $\mathbf{F}(\mathbf{k}, \mathbf{k}_0)$:

$$\mathbf{F}(\mathbf{k}, \mathbf{k}_0) = \frac{i}{4\pi} \oint_{S_1} e^{-i\mathbf{k} \cdot \mathbf{x}'} [k(\mathbf{n}' \times \mathbf{B}_s) + \mathbf{k} \times (\mathbf{n}' \times \mathbf{E}_s) - \mathbf{k}(\mathbf{n}' \cdot \mathbf{E}_s)] da' \quad (9.137)$$

Note carefully how $\mathbf{F}(\mathbf{k}, \mathbf{k}_0)$ depends explicitly on the outgoing direction of \mathbf{k} . The dependence on the incident direction specified by \mathbf{k}_0 is implicit in the

Fig. 9.11 Scattering geometry. An incident plane wave with wave vector \mathbf{k}_0 and fields $(\mathbf{E}_i, \mathbf{B}_i)$ is scattered by an obstacle (the scatterer), giving rise to scattered fields $(\mathbf{E}_s, \mathbf{B}_s)$ that propagate as spherically diverging waves at large distances. The surface S_1 completely encloses the scatterer.

scattered fields \mathbf{E}_s and \mathbf{B}_s . Since we know that $\mathbf{k} \cdot \mathbf{F} = 0$, it must be true that in (9.137) the component parallel to \mathbf{k} of the first integral cancels the third integral. It is therefore convenient to resolve the integrand in (9.137) into components parallel and perpendicular to \mathbf{k} , and to exhibit the transversality of \mathbf{F} explicitly:

$$\mathbf{F}(\mathbf{k}, \mathbf{k}_0) = \frac{1}{4\pi i} \mathbf{k} \times \oint_{S_1} e^{-i\mathbf{k} \cdot \mathbf{x}'} \left[\frac{\mathbf{k} \times (\mathbf{n}' \times \mathbf{B}_s)}{k} - \mathbf{n}' \times \mathbf{E}_s \right] da' \quad (9.138)$$

Alternatively, we can ask for the amplitude of scattered radiation with wave vector \mathbf{k} and polarization $\boldsymbol{\epsilon}$. This is given by

$$\boldsymbol{\epsilon}^* \cdot \mathbf{F}(\mathbf{k}, \mathbf{k}_0) = \frac{i}{4\pi} \oint_{S_1} e^{-i\mathbf{k} \cdot \mathbf{x}'} [k \boldsymbol{\epsilon}^* \cdot (\mathbf{n}' \times \mathbf{B}_s) + \boldsymbol{\epsilon}^* \cdot (\mathbf{k} \times (\mathbf{n}' \times \mathbf{E}_s))] da' \quad (9.139)$$

The terms in square brackets can be interpreted as effective electric and magnetic surface currents on S_1 acting as sources for the scattered fields. The various equivalent forms (9.137)–(9.139) are valuable as starting points for the discussion of the scattering of short-wavelength radiation (Section 9.13) and in the derivation of the optical theorem (Section 9.14).

9.10 Vectorial Diffraction Theory

The vectorial Kirchhoff integral (9.136) can be used as the basis of an approximate theory of diffraction in exactly the same manner as described below (9.125) for the scalar theory. Unfortunately, the inconsistencies of the scalar Kirchhoff approximation persist.

For the special case of a thin, perfectly conducting, plane screen with

apertures, however, it is possible to obtain vectorial relations, akin to the generalized Kirchhoff integral (9.127) or (9.131), in which the boundary conditions *are* satisfied and which are amenable to consistent approximations. The plane screen is taken at $z=0$, with the sources supposed to be in the region $z<0$, and the diffracted fields to be observed in the region $z>0$. It is convenient to divide the fields into two parts,

$$\mathbf{E} = \mathbf{E}^{(0)} + \mathbf{E}', \quad \mathbf{B} = \mathbf{B}^{(0)} + \mathbf{B}' \quad (9.140)$$

where $\mathbf{E}^{(0)}$, $\mathbf{B}^{(0)}$ are the fields produced by the sources in the absence of any screen or obstacle (defined for both $z<0$ and $z>0$), and \mathbf{E}' and \mathbf{B}' are the fields caused by the presence of the plane screen. For $z>0$, \mathbf{E}' , \mathbf{B}' are the diffracted fields, while for $z<0$, they are the reflected fields. We will call \mathbf{E}' , \mathbf{B}' the scattered fields when considering both $z<0$ and $z>0$. The scattered fields can be considered as having their origin in the surface current density and surface charge density that are necessarily produced on the screen in order to satisfy the boundary conditions. Certain reflection properties in z of the scattered fields follow from the fact that the surface current and charge densities are confined to the $z=0$ plane. A vector potential \mathbf{A}' and a scalar potential Φ' can be used to construct \mathbf{E}' and \mathbf{B}' . Since the surface current flow has no z -component, $A'_z=0$. Furthermore, A'_x , A'_y , and Φ' are evidently even functions of z . The relation of the fields to the potentials shows that the scattered fields have the reflection symmetries,

$$\begin{aligned} E'_x, E'_y, B'_z & \text{ are even in } z \\ E'_z, B'_x, B'_y & \text{ are odd in } z \end{aligned} \quad (9.141)$$

The fields that are odd in z are not necessarily zero over the whole plane $z=0$. Where the conducting surface exists, $E'_z \neq 0$ implies an associated surface charge density, equal on the two sides of the surface. Similarly, nonvanishing tangential components of \mathbf{B} imply a surface current density, equal in magnitude and direction on both sides of the screen. Only in the aperture does continuity require that E'_z , B'_x , B'_y vanish. This leads to the statement that in the apertures of a perfectly conducting plane screen the normal component of \mathbf{E} and the tangential components of \mathbf{B} are the same as in the absence of the screen.

The generalized Kirchhoff integral (9.129) for Neumann boundary conditions can be applied to the components of the vector potential \mathbf{A}' . The normal derivatives on the right can be expressed in terms of components of \mathbf{B}' . The result, written vectorially is

$$\mathbf{A}'(\mathbf{x}) = \frac{1}{2\pi} \int_{\text{screen}} (\mathbf{n} \times \mathbf{B}') \frac{e^{ikR}}{R} da' \quad (9.142)$$

In view of the preceeding remarks about the surface current and the tangential components of \mathbf{B}' , (9.142) could perhaps have been written down directly. The

scattered magnetic field can be obtained by taking the curl of (9.142):

$$\mathbf{B}'(\mathbf{x}) = \frac{1}{2\pi} \nabla \times \int_{\text{screen}} (\mathbf{n} \times \mathbf{B}') \frac{e^{ikR}}{R} da' \quad (9.143)$$

In (9.142) and (9.143) the integrand can be evaluated on either side of the screen with \mathbf{n} being normal to the surface. For definiteness, we specify that \mathbf{n} is a unit normal in the positive z direction and the integrand is to be evaluated at $z=0^+$. The integration extends over the metallic part of the screen; $\mathbf{B}'_{\text{tan}}=0$ in the apertures. The electric field \mathbf{E}' can be calculated from $\mathbf{E}' = (i/k)\nabla \times \mathbf{B}'$.

Equation (9.143) can be used for approximations in a consistent way. It is most useful when the diffracting obstacles consist of one or more finite flat segments at $z=0$, for example, a circular disc. Then the surface current on the obstacles can be approximated in some way, for instance, by using the incident field $\mathbf{B}^{(0)}$ in the integrand. We then have a vectorial version of the generalized Kirchhoff's approximation of the previous section.

It is useful to construct an expression equivalent to (9.143) for the electric field. From the symmetry of the source-free Maxwell equations with respect to \mathbf{E} and \mathbf{B} it is evident that the electric field \mathbf{E}' can be expressed by analogy with (9.143), as

$$\mathbf{E}'(\mathbf{x}) = \pm \frac{1}{2\pi} \nabla \times \int_{S_1} (\mathbf{n} \times \mathbf{E}') \frac{e^{ikR}}{R} da' \quad (9.144)$$

where it is assumed that \mathbf{E}' is known on the whole surface S_1 at $z=0^+$. The upper (lower) sign applies for $z>0$ ($z<0$). It can be verified that (9.144) satisfies the Maxwell equations and yields consistent boundary values at $z=0$. The reason for the difference in sign for $z \geq 0$, as compared to (9.143) for \mathbf{B}' , is the opposite reflection properties of \mathbf{E}' compared to \mathbf{B}' [see (9.141)].

There is a practical difficulty with (9.144) as it stands. The integration in (9.144) is over the *whole plane* at $z=0$. We cannot exploit the vanishing of the tangential components of the electric field on the metallic portions of the screen because it is the *total* electric field whose tangential components vanish, not those of \mathbf{E}' . The difficulty can be removed by use of linear superposition. We add fields $(\mathbf{E}^{(1)}, \mathbf{B}^{(1)})$ possessing the symmetry under reflections of (9.141). They can thus be considered as arising from currents on the surface at $z=0$. In the region $z>0$ we choose

$$\mathbf{E}^{(1)} = -\mathbf{E}^{(0)}, \quad \mathbf{B}^{(1)} = -\mathbf{B}^{(0)} \quad (9.145)$$

The added fields thus cancel the unperturbed fields produced by the source and make \mathbf{E}' , \mathbf{B}' the total fields for $z>0$. The symmetry (9.141) under reflection shows that for $z<0$ the components of $\mathbf{E}^{(1)}$ and $\mathbf{B}^{(1)}$ are

$$\begin{aligned} E_x^{(1)}(z) &= -E_x^{(0)}(-z), & B_x^{(1)}(z) &= +B_x^{(0)}(-z) \\ E_y^{(1)}(z) &= -E_y^{(0)}(-z), & B_y^{(1)}(z) &= +B_y^{(0)}(-z) \\ E_z^{(1)}(z) &= +E_z^{(0)}(-z), & B_z^{(1)}(z) &= -B_z^{(0)}(-z) \end{aligned} \quad (9.146)$$

It is understood that x, y are the same on both sides of each equation. In this region of $z < 0$ the superposition ($\mathbf{E}^{(0)} + \mathbf{E}^{(1)}, \mathbf{B}^{(0)} + \mathbf{B}^{(1)}$) is just the field configuration that is produced by a source generating primary fields ($\mathbf{E}^{(0)}, \mathbf{B}^{(0)}$) that are reflected by a perfectly conducting surface filling the entire plane at $z = 0$.

We have now arrived at an alternative specification of diffraction by a perfectly conducting plane screen with certain apertures in it. Let $\mathbf{E}^{(0)}, \mathbf{B}^{(0)}$ be the fields generated by the sources in the region $z < 0$. Let $\mathbf{E}^{(1)}, \mathbf{B}^{(1)}$ be the reflected fields in $z < 0$, assuming that the screen at $z = 0$ has no apertures in it [the fields $\mathbf{E}^{(1)}$ and $\mathbf{B}^{(1)}$ are given by (9.146)]. Define the diffracted electric field \mathbf{E}'' by

$$\mathbf{E}''(\mathbf{x}) = \frac{1}{2\pi} \nabla \times \int_{\text{Apertures}} (\mathbf{n} \times \mathbf{E}) \frac{e^{ikR}}{R} da' \quad (9.147)$$

where the integration is only over the apertures in the screen and \mathbf{E} in the integrand is the total tangential electric field in the apertures. Then in the diffraction region ($z > 0$) the total electric field is

$$\mathbf{E}(\mathbf{x}) = \mathbf{E}''(\mathbf{x}) \quad (9.148)$$

In the illuminated region ($z < 0$) the total electric field is

$$\mathbf{E}(\mathbf{x}) = \mathbf{E}^{(0)}(\mathbf{x}) + \mathbf{E}^{(1)}(\mathbf{x}) - \mathbf{E}''(\mathbf{x}) \quad (9.149)$$

where for both regions $\mathbf{E}''(\mathbf{x})$ is given by (9.147). This form of solution in terms of tangential electric field in the apertures of a perfectly conducting plane screen was first obtained by Smythe.* It can serve as the basis of a consistent scheme of approximation with the approximate solutions for \mathbf{E}'' satisfying the required boundary conditions at $z = 0$ and at infinity. In a later section and in the problems some examples are discussed.

9.11 Babinet's Principle of Complementary Screens

Before discussing examples of diffraction we wish to establish a useful relation called *Babinet's principle*. Babinet's principle relates the diffraction fields of one diffracting screen to those of the complementary screen. We first discuss the principle in the scalar Kirchhoff approximation. The diffracting screen is assumed to lie in some surface S which divides space into regions I and II in the sense of Section 9.8. The screen occupies all of the surface S except for certain apertures. The complementary screen is that diffracting screen which is obtained by replacing the apertures by screen and the screen by apertures. If the surface of the original screen is S_a and that of the complementary screen is S_b , then $S_a + S_b = S$, as shown schematically in Fig. 9.12.

* W. R. Smythe, *Phys. Rev.* **72**, 1066 (1947). See also *Smythe*, Section 12.18.

Fig. 9.12 A diffraction screen S_a and its complementary diffraction screen S_b .

If there are sources inside S (in region I) which give rise to a field $\psi(\mathbf{x})$, then in the absence of either screen the field $\psi(\mathbf{x})$ in region II is given by the Kirchhoff integral (9.125) where the surface integral is over the entire surface S . With the screen S_a in position, the field $\psi_a(\mathbf{x})$ in region II is given in the Kirchhoff approximation by (9.125) with the source field ψ in the integrand and the surface integral only over S_b (the apertures). Similarly, for the complementary screen S_b , the field $\psi_b(\mathbf{x})$ is given in the same approximation by a surface integral over S_a . Evidently, then, we have the following relation between the diffraction fields ψ_a and ψ_b :

$$\psi_a + \psi_b = \psi \quad (9.150)$$

This is Babinet's principle as usually formulated in optics. If ψ represents an incident plane wave, for example, Babinet's principle says that the diffraction patterns away from the incident direction are the same for the original screen and its complement.

The result (9.150) also follows from the generalized Kirchhoff integrals (9.127) or (9.129) if the amplitude or its normal derivative is taken equal to that of the incident wave in the apertures and zero elsewhere, in the spirit of the Kirchhoff approximation. All these formulations of Babinet's principle are unsatisfactory in two respects: they are statements about scalar fields, and they are based on a Kirchhoff approximation.

A rigorous statement of Babinet's principle for electromagnetic fields can be made for a thin, perfectly conducting plane screen and its complement. The result follows from the two alternative formulations of this diffraction problem given in the previous section. The original diffraction problem and its complementary problem are defined by the source fields and screens as follows:

Original	$\mathbf{E}^{(0)}, \quad \mathbf{B}^{(0)}; \quad S_a$	(9.151)
Complement	$\mathbf{E}_c^{(0)} = \mathbf{B}^{(0)}, \quad \mathbf{B}_c^{(0)} = -\mathbf{E}^{(0)}; \quad S_b$	

The complementary situation has a screen that is the complement of the original and has source fields with opposite polarization characteristics. For the original screen S_a the electric field for $z > 0$ is, according to (9.147) and (9.148),

$$\mathbf{E}(\mathbf{x}) = \frac{1}{2\pi} \nabla \times \int_{S_b} (\mathbf{n} \times \mathbf{E}) \frac{e^{ikR}}{R} da' \quad (9.152)$$

For the complementary screen S_b we choose to use (9.143) instead of (9.147) to express the complementary scattered magnetic field \mathbf{B}'_c for $z > 0$ as

$$\mathbf{B}'_c(\mathbf{x}) = \frac{1}{2\pi} \nabla \times \int_{S_b} (\mathbf{n} \times \mathbf{B}'_c) \frac{e^{ikR}}{R} da' \quad (9.153)$$

In both (9.152) and (9.153) the integration is over the screen S_b because of the boundary conditions on \mathbf{E} and \mathbf{B}'_c in the two cases. Mathematically, (9.152) and (9.153) are of the same form. From the linearity of the Maxwell equations and the relation between the original and complementary source fields, it follows that in the region $z > 0$ the total electric field for the screen S_a is numerically equal to the scattered magnetic field for the complementary screen S_b :

$$\mathbf{E}(\mathbf{x}) = \mathbf{B}'_c(\mathbf{x})$$

The other fields are related by

$$\mathbf{B}(\mathbf{x}) = -\mathbf{E}'_c(\mathbf{x})$$

where the minus sign is a consequence of the requirement of outgoing radiation flux at infinity, just as for the source fields. If use is made of (9.140) for the complementary problem in order to obtain relations between the total fields in the region $z > 0$, *Babinet's principle* for a plane, perfectly conducting thin screen and its complement states that the original fields (\mathbf{E} , \mathbf{B}) and the complementary fields (\mathbf{E}_c , \mathbf{B}_c) are related according to

$$\begin{aligned} \mathbf{E} - \mathbf{B}_c &= \mathbf{E}^{(0)} \\ \mathbf{B} + \mathbf{E}_c &= \mathbf{B}^{(0)} \end{aligned} \quad (9.154)$$

for $z > 0$, provided the complementary diffraction problems are defined by (9.151). These relations are the vectorial analogs of (9.150); they are exact, not approximate, statements for the idealized problem of a perfectly conducting plane screen. For practical situations (finite, but large, conductivity; curved screens whose radii of curvature are large compared to aperture dimensions, etc.), the vectorial Babinet's principle can be expected to hold approximately. It says that the diffracted intensity in directions other than that of the incident field is the same for a screen and its complement. The polarization characteristics are rotated, but this conforms with the altered polarization of the complementary source fields (9.151).

The rigorous vector formulation of Babinet's principle is very useful in

Fig. 9.13 Equivalent radiators according to Babinet's principle.

microwave problems. For example, consider a narrow slot cut in an infinite, plane, conducting sheet and illuminated with fields that have the magnetic induction along the slot and the electric field perpendicular to it, as shown in Fig. 9.13. The radiation pattern from the slot will be the same as that of a thin linear antenna with its driving electric field along the antenna, as considered in Sections 9.2 and 9.4. The polarization of the radiation will be opposite for the two systems. Elaboration of these ideas makes it possible to design antenna arrays by cutting suitable slots in the sides of wave guides.*

9.12 Diffraction by a Circular Aperture, Remarks on Small Apertures

The subject of diffraction has been extensively studied since Kirchhoff's original work, both in optics, where the scalar theory based on (9.125) generally suffices, and in microwave generation and transmission, where more accurate solutions are needed. There exist specialized treatises devoted entirely to the subject of diffraction and scattering. We will content ourselves with a few examples to illustrate the use of the scalar and vector theorems (9.125), (9.131) and (9.147) and to compare the accuracy of the approximation schemes.

Historically, diffraction patterns were classed as Fresnel or Fraunhofer diffraction, depending on the relative geometry involved. There are three length scales to consider, the size d of the diffracting system, the distance r from the system to the observation point, and the wavelength λ . A diffraction pattern only becomes manifest for $r \gg d$. Then in expressions like (9.132) or (9.147) slowly varying factors in the integrands can be treated as constants. Only the phase factor kR in e^{ikR} needs to be handled with some care. With $r \gg d$, it can be expanded as

$$kR = kr - k \mathbf{n} \cdot \mathbf{x}' + \frac{k}{2r} [r'^2 - (\mathbf{n} \cdot \mathbf{x}')^2] + \dots$$

where $\mathbf{n} = \mathbf{x}/r$ is a unit vector in the direction of observation. The successive terms are of order (kr) , (kd) , $(kd)(d/r)$, The term *Fraunhofer diffraction* applies if the

* See, for example, *Silver*, Chapter 9.

third and higher terms are negligible compared to unity. For small diffracting systems this always holds since $kd \ll 1$, and we have supposed $d/r \ll 1$. But for systems that are large compared to a wavelength, (kd^2/r) may be of order unity or larger even though $d/r \ll 1$. Then the term *Fresnel diffraction* applies. In most practical applications the simpler Fraunhofer limit is appropriate. Far enough from any diffracting system it always holds. We consider only the Fraunhofer limit here (except for Problem 9.16).

If the observation point is far from the diffracting system, expansion (9.7) can be used for $R = |\mathbf{x} - \mathbf{x}'|$. Keeping only lowest-order terms in $(1/kr)$, the scalar Kirchhoff expression (9.125) becomes

$$\psi(\mathbf{x}) = -\frac{e^{ikr}}{4\pi r} \int_{S_1} e^{-ik \cdot \mathbf{x}'} [\mathbf{n} \cdot \nabla' \psi(\mathbf{x}') + ik \cdot \mathbf{n} \psi(\mathbf{x}')] da' \quad (9.155)$$

where \mathbf{x}' is the coordinate of the element of surface area da' , r is the length of the vector \mathbf{x} from the origin O to the observation point P , and $\mathbf{k} = k(\mathbf{x}/r)$ is the wave vector in the direction of observation, as indicated in Fig. 9.14. For a plane surface we can use the vector expression (9.147) which reduces in this limit to

$$\mathbf{E}(\mathbf{x}) = \frac{ie^{ikr}}{2\pi r} \mathbf{k} \times \int_{S_1} \mathbf{n} \times \mathbf{E}(\mathbf{x}') e^{-ik \cdot \mathbf{x}'} da' \quad (9.156)$$

As an example of diffraction we consider a plane wave incident at an angle α on a thin, perfectly conducting screen with a circular hole of radius a in it. The polarization vector of the incident wave lies in the plane of incidence. Figure 9.15 shows an appropriate system of coordinates. The screen lies in the x - y plane with the opening centered at the origin. The wave is incident from below, so that the domain $z > 0$ is the region of diffraction fields. The plane of incidence is taken to be the x - z plane. The incident wave's electric field, written out explicitly in rectangular components, is

$$\mathbf{E}_i = E_0(\epsilon_1 \cos \alpha - \epsilon_3 \sin \alpha) e^{ik(\cos \alpha z + \sin \alpha x)} \quad (9.157)$$

In calculating the diffraction field with (9.155) or (9.156) we will make the customary approximation that the exact field in the surface integral may be replaced by the incident field. For the vector relation (9.156) we need

$$(\mathbf{n} \times \mathbf{E}_i)_{z=0} = E_0 \epsilon_2 \cos \alpha e^{ik \sin \alpha x'} \quad (9.158)$$

Fig. 9.14

Fig. 9.15 Diffraction by a circular hole of radius a .

Then, introducing plane polar coordinates for the integration over the opening, we have

$$\mathbf{E}(\mathbf{x}) = \frac{ie^{ikr}E_0 \cos \alpha}{2\pi r} (\mathbf{k} \times \mathbf{e}_z) \int_0^a \rho d\rho \int_0^{2\pi} d\beta e^{ik\rho [\sin \alpha \cos \beta - \sin \theta \cos(\phi - \beta)]} \quad (9.159)$$

where θ, ϕ are the spherical angles of \mathbf{k} . If we define the angular function,

$$\xi = (\sin^2 \theta + \sin^2 \alpha - 2 \sin \theta \sin \alpha \cos \phi)^{1/2} \quad (9.160)$$

the angular integral can be transformed into

$$\frac{1}{2\pi} \int_0^{2\pi} d\beta' e^{-ik\rho\xi \cos \beta'} = J_0(k\rho\xi)$$

Then the radial integral in (9.159) can be done directly. The resulting electric field in the vector Smythe-Kirchhoff approximation is

$$\mathbf{E}(\mathbf{x}) = \frac{ie^{ikr}}{r} a^2 E_0 \cos \alpha (\mathbf{k} \times \mathbf{e}_z) \frac{J_1(ka\xi)}{ka\xi} \quad (9.161)$$

The time-averaged diffracted power per unit solid angle is

$$\frac{dP}{d\Omega} = P_i \cos \alpha \frac{(ka)^2}{4\pi} (\cos^2 \theta + \cos^2 \phi \sin^2 \theta) \left| \frac{2J_1(ka\xi)}{ka\xi} \right|^2 \quad (9.162)$$

where

$$P_i = \left(\frac{cE_0^2}{8\pi} \right) \pi a^2 \cos \alpha \quad (9.163)$$

is the total power normally incident on the aperture. If the opening is large compared to a wavelength ($ka \gg 1$), the factor $[2J_1(ka\xi)/ka\xi]^2$ peaks sharply to a value of unity at $\xi=0$ and falls rapidly to zero (with small secondary maxima) within a region $\Delta\xi \sim (1/ka)$ away from $\xi=0$. This means that the main part of the wave passes through the opening in the manner of geometrical optics; only slight

diffraction effects occur.* For $ka \sim 1$ the Bessel-function varies comparatively slowly in angle; the transmitted wave is distributed in directions very different from the incident direction. For $ka \ll 1$, the angular distribution is entirely determined by the factor $(\mathbf{k} \times \mathbf{e}_z)$ in (9.161). But in this limit the assumption of an unperturbed field in the aperture breaks down badly.

The total transmitted power can be obtained by integrating (9.162) over all angles in the forward hemisphere. The ratio of transmitted power to incident power is called the *transmission coefficient* T :

$$T = \frac{\cos \alpha}{\pi} \int_0^{2\pi} d\phi \int_0^{\pi/2} (\cos^2 \theta + \cos^2 \phi \sin^2 \theta) \left| \frac{J_1(ka\xi)}{\xi} \right|^2 \sin \theta d\theta \quad (9.164)$$

In the two extreme limits $ka \gg 1$ and $ka \ll 1$, the transmission coefficient approaches the values,

$$T \rightarrow \begin{cases} \cos \alpha, & ka \gg 1 \\ \frac{1}{3}(ka)^2 \cos \alpha, & ka \ll 1 \end{cases}$$

The long-wavelength limit ($ka \ll 1$) is suspect because of our approximations, but it shows that the transmission is small for very small holes. For normal incidence ($\alpha = 0$) the transmission coefficient (9.164) can be written

$$T = \int_0^{\pi/2} J_1^2(ka \sin \theta) \left(\frac{2}{\sin \theta} - \sin \theta \right) d\theta$$

With the help of the integral relations,

$$\left. \begin{aligned} \int_0^{\pi/2} J_n^2(z \sin \theta) \frac{d\theta}{\sin \theta} &= \int_0^{2z} \frac{J_{2n}(t)}{t} dt \\ \int_0^{\pi/2} J_n^2(z \sin \theta) \sin \theta d\theta &= \frac{1}{2z} \int_0^{2z} J_{2n}(t) dt \end{aligned} \right\} \quad (9.165)$$

and the recurrence formulas (3.87) and (3.88), the transmission coefficient can be put in the alternative forms,

$$T = \begin{cases} 1 - \frac{1}{ka} \sum_{m=0}^{\infty} J_{2m+1}(2ka) \\ 1 - \frac{1}{2ka} \int_0^{2ka} J_0(t) dt \end{cases}$$

* To see this explicitly we expand ξ around the geometrical optics direction $\theta = \alpha$, $\phi = 0$:

$$\xi \approx \sqrt{(\theta - \alpha)^2 + \sin^2 \alpha \phi^2}$$

For $ka \gg 1$ it is evident that $ka\xi \gg 1$ as soon as θ departs appreciably from α , or ϕ from zero, or both.

The transmission coefficient increases more or less monotonically as ka increases, with small oscillations superposed. For $ka \gg 1$, the second form can be used to obtain an asymptotic expression,

$$T \approx 1 - \frac{1}{2ka} - \frac{1}{2\sqrt{\pi}(ka)^{3/2}} \sin\left(2ka - \frac{\pi}{4}\right) + \dots \quad (9.166)$$

which exhibits the small oscillations explicitly. These approximate expressions for T give the general behavior as a function of ka , but are not very accurate. Exact calculations, as well as more accurate approximate ones, have been made for the circular opening. These are compared with each other in the book by King and Wu (Fig. 41, p. 126). The correct asymptotic expression does not contain the $1/2ka$ term in (9.166), and the coefficient of the term in $(ka)^{-3/2}$ is twice as large.

We now wish to compare our results of the *vector* Smythe-Kirchhoff approximation with the usual scalar theory based on (9.125). For a wave not normally incident the question immediately arises as to what to choose for the scalar function $\psi(\mathbf{x})$. Perhaps the most consistent assumption is to take the magnitude of the electric or magnetic field. Then the diffracted intensity is treated consistently as proportional to the absolute square of (9.125). If a component of \mathbf{E} or \mathbf{B} is chosen for ψ , we must then decide whether to keep or throw away radial components of the diffracted field in calculating the diffracted power. Choosing the magnitude of \mathbf{E} for ψ , we have, by straightforward calculation with (9.155),

$$\psi(\mathbf{x}) = -ik \frac{e^{ikr}}{r} a^2 E_0 \left(\frac{\cos \alpha + \cos \theta}{2} \right) \frac{J_1(ka\xi)}{ka\xi}$$

as the scalar equivalent of (9.161). The power radiated per unit solid angle in the *scalar* Kirchhoff approximation is

$$\frac{dP}{d\Omega} \approx P_i \frac{(ka)^2}{4\pi} \cos \alpha \left(\frac{\cos \alpha + \cos \theta}{2 \cos \alpha} \right)^2 \left| \frac{2J_1(ka\xi)}{ka\xi} \right|^2 \quad (9.167)$$

where P_i is given by (9.163). If the alternative scalar formula (9.131) is used, the obliquity factor $(\cos \alpha + \cos \theta)/2$ in (9.167) is replaced by $\cos \theta$.

If we compare the vector Smythe-Kirchhoff result (9.162) with (9.167), we see similarities and differences. Both formulas contain the same "diffraction" distribution factor $[J_1(ka\xi)/ka\xi]^2$ and the same dependence on wave number. But the scalar result has no azimuthal dependence (apart from that contained in ξ), whereas the vector expression does. The azimuthal variation comes from the polarization properties of the field, and must be absent in a scalar approximation. For normal incidence ($\alpha = 0$) and $ka \gg 1$ the polarization dependence is unimportant. The diffraction is confined to very small angles in the forward direction. Then all scalar and vector approximations reduce to the common

Fig. 9.16 Fraunhofer diffraction pattern for a circular opening one wavelength in diameter in a thin, plane, conducting sheet. The plane wave is incident on the screen at 45° . The solid curves are the vector Smythe-Kirchhoff approximation, while the dotted curves are the scalar approximation. (a) The intensity distribution in the plane of incidence (E plane). (b) The intensity distribution (enlarged 2.5 times) perpendicular to the plane of incidence (H plane).

expression,

$$\frac{dP}{d\Omega} \approx P_i \frac{(ka)^2}{\pi} \left| \frac{J_1(ka \sin \theta)}{ka \sin \theta} \right|^2 \quad (9.168)$$

The vector and scalar approximations are compared in Fig. 9.16 for the angle of incidence equal to 45° and for an aperture one wavelength in diameter ($ka = \pi$). The angular distribution is shown in the plane of incidence (containing the electric field vector of the incident wave) and a plane perpendicular to it. The solid (dotted) curve gives the vector (scalar) approximation in each case. We see that for $ka = \pi$ there is a considerable disagreement between the two approximations. There is reason to believe that the Smythe-Kirchhoff result is close to the correct one, even though the approximation breaks down seriously for $ka \lesssim 1$. The vector approximation and exact calculations for a rectangular opening yield results in surprisingly good agreement, even down to $ka \sim 1$.*

The diffraction by apertures or obstacles whose dimensions are small compared to a wavelength requires methods different from the Kirchhoff or

* See J. A. Stratton and L. J. Chu, *Phys. Rev.*, **56**, 99 (1939), for a series of figures comparing the vector Smythe-Kirchhoff approximation with exact calculations by P. M. Morse and P. J. Rubenstein, *Phys. Rev.*, **54**, 895 (1938). The alert reader may be puzzled by the apparent discrepancy in the dates of Smythe's publication (*loc. cit.*) and of Stratton and Chu. The two calculations yield the same result, though quite different in appearance and detail of derivation, the earlier one involving a line integral around the boundary of the aperture as well as a surface integral over it.

Kirchhoff-like approximation. The exact formula (9.147) for a plane screen can be used as a starting point. If the radiation fields of (9.147) are expanded in multipoles, as in Sections 9.2–9.3, effective multipole moments (9.72) and (9.76) can be identified in terms of integrals of the exact electric field in the aperture. The derivation of these effective moments is left as Problem 9.15. Once the dipole moments of an aperture are known, the diffraction can be calculated merely by using the dipole fields of Sections 9.2 and 9.3. The example of a circular aperture with effective moments (9.77) is left to the problems. The whole discussion of the physical picture parallels that of Section 9.5(d) and will not be repeated here.

9.13 Scattering in the Short-Wavelength Limit

Scattering in the long-wavelength limit has been discussed in Sections 9.6 and 9.7. The opposite limit, similar to the Kirchhoff domain of diffraction, is a scattering by obstacles large compared to a wavelength. Just as for diffraction by a screen, the zeroth approximation is given by classical ray theory. The wave aspects of the fields give corrections to this, with the scattering confined to angular regions only slightly away from the paths of geometrical optics. For a thin, flat obstacle, the techniques of Section 9.10, perhaps with Babinet's principle, can be used. But for other obstacles we base the calculation on the integral expression (9.139) for the scattering amplitude in terms of the scattered fields \mathbf{E}_s , \mathbf{B}_s on a surface S_1 just outside the scatterer.

In the absence of knowledge about the correct fields \mathbf{E}_s and \mathbf{B}_s on the surface, we must make some approximations. If the wavelength is short compared to the dimensions of the obstacle, the surface can be divided approximately into an illuminated region and a shadow region.* The boundary between these regions is sharp only in the limit of geometrical optics. The transition region can be shown to have a width of the order of $(2/kR)^{1/3}R$, where R is a typical radius of curvature of the surface. Since R is of the order of magnitude of the dimensions of the obstacle, the short-wavelength limit will approximately satisfy the geometrical condition. In the shadow region the scattered fields on the surface must be very nearly equal and opposite to the incident fields, regardless of the nature of the scatterer, provided it is "opaque." In the illuminated region, on the other hand, the scattered fields at the surface will depend on the properties of the obstacle. If the wavelength is short compared to the minimum radius of curvature, the Fresnel equations of Section 7.3 can be utilized, treating the surface as locally flat. Eventually we will specialize to a perfectly conducting obstacle, for which the tangential \mathbf{E}_s and the normal \mathbf{B}_s must be equal and

* For a very similar treatment of the scattering of a scalar wave by a sphere, see *Morse and Feshbach*, pp. 1551–1555.

opposite to the corresponding incident fields, while the tangential \mathbf{B}_s and normal \mathbf{E}_s will be approximately equal to the incident values [see (9.146)].

Because of the generality of the contribution from the shadow region, it is desirable to consider it separately. We write

$$\boldsymbol{\epsilon}^* \cdot \mathbf{F} = \boldsymbol{\epsilon}^* \cdot \mathbf{F}_{sh} + \boldsymbol{\epsilon}^* \cdot \mathbf{F}_{ill} \quad (9.169)$$

If the incident wave is a plane wave with wave vector \mathbf{k}_0 and polarization $\boldsymbol{\epsilon}_0$,

$$\begin{aligned} \mathbf{E}_i &= E_0 \boldsymbol{\epsilon}_0 e^{i\mathbf{k}_0 \cdot \mathbf{x}} \\ \mathbf{B}_i &= \mathbf{k}_0 \times \mathbf{E}_i / k \end{aligned} \quad (9.170)$$

the shadow contribution, from (9.139) with $\mathbf{E}_s \approx -\mathbf{E}_i$, $\mathbf{B}_s \approx -\mathbf{B}_i$, is

$$\boldsymbol{\epsilon}^* \cdot \mathbf{F}_{sh} = \frac{E_0}{4\pi i} \int_{sh} \boldsymbol{\epsilon}^* \cdot [\mathbf{n}' \times (\mathbf{k}_0 \times \boldsymbol{\epsilon}_0) + \mathbf{k} \times (\mathbf{n}' \times \boldsymbol{\epsilon}_0)] e^{i(\mathbf{k}_0 - \mathbf{k}) \cdot \mathbf{x}'} da' \quad (9.171)$$

where the integration is only over the part of S_1 in shadow. A rearrangement of the vector products allows (9.171) to be written

$$\boldsymbol{\epsilon}^* \cdot \mathbf{F}_{sh} = \frac{E_0}{4\pi i} \int_{sh} \boldsymbol{\epsilon}^* \cdot [(\mathbf{k} + \mathbf{k}_0) \times (\mathbf{n}' \times \boldsymbol{\epsilon}_0) + (\mathbf{n}' \cdot \boldsymbol{\epsilon}_0) \mathbf{k}_0] e^{i(\mathbf{k}_0 - \mathbf{k}) \cdot \mathbf{x}'} da' \quad (9.172)$$

In the short wavelength limit the magnitudes of $\mathbf{k}_0 \cdot \mathbf{x}'$ and $\mathbf{k} \cdot \mathbf{x}'$ are large compared to unity. The exponential factor in (9.172) will oscillate rapidly and cause the integrand to have a very small average value except in the forward direction where $\mathbf{k} \approx \mathbf{k}_0$. In that forward region, $\theta \approx 1/kR$, the second term in the square bracket is negligible compared to the first because $(\boldsymbol{\epsilon}^* \cdot \mathbf{k}_0)/k$ is of the order of $\sin \theta \ll 1$ (remember $\boldsymbol{\epsilon}^* \cdot \mathbf{k} \equiv 0$ and $\mathbf{k}_0 \approx \mathbf{k}$). Thus (9.172) can be approximated by

$$\boldsymbol{\epsilon}^* \cdot \mathbf{F}_{sh} \approx \frac{iE_0}{2\pi} \boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0 \int_{sh} e^{i(\mathbf{k}_0 - \mathbf{k}) \cdot \mathbf{x}'} (\mathbf{k}_0 \cdot \mathbf{n}') da'$$

The integral over the shadowed side of the obstacle has, in this approximation, the remarkable property of *depending only upon the projected area* normal to the incident direction and not at all on the detailed shape of the obstacle. This can be seen from the fact that $(\mathbf{k}_0 \cdot \mathbf{n}') da' = k dx' dy' = k d^2x_\perp$ is just k times the projected element of area and $(\mathbf{k}_0 - \mathbf{k}) \cdot \mathbf{x}' = k(1 - \cos \theta)z' - \mathbf{k}_\perp \cdot \mathbf{x}_\perp \approx -\mathbf{k}_\perp \cdot \mathbf{x}_\perp$. Here we have chosen \mathbf{k}_0 along the z axis, introduced two-dimensional vectors, $\mathbf{x}_\perp = x'\mathbf{e}_1 + y'\mathbf{e}_2$, $\mathbf{k}_\perp = k_x\mathbf{e}_1 + k_y\mathbf{e}_2$ in the plane perpendicular to \mathbf{k}_0 and have approximated to small angles. The final form of the shadow contribution to the scattering when $kR \gg 1$ and $\theta \ll 1$ is therefore

$$\boldsymbol{\epsilon}^* \cdot \mathbf{F}_{sh} \approx \frac{ik}{2\pi} E_0 (\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0) \int_{sh} e^{-i\mathbf{k}_\perp \cdot \mathbf{x}_\perp} d^2x_\perp \quad (9.173)$$

In this limit all scatterers of the same projected area give the same shadow

scattering contribution. The polarization character of the scattered radiation is given by the factor $\epsilon^* \cdot \epsilon_0$. Since the scattering is at small angles, the dominant contribution has the same polarization as the incident wave. In quantum-mechanical language we say that the shadow scattering involves *no spin flip*.

For example, consider a scatterer whose projected area is a circular disc of radius a . Then

$$\int_{\text{sh}} e^{-i\mathbf{k}_\perp \cdot \mathbf{x}_\perp} d^2x_\perp = 2\pi a^2 \frac{J_1(ka \sin \theta)}{ka \sin \theta} \quad (9.174)$$

and the shadow scattering amplitude is

$$\epsilon^* \cdot \mathbf{F}_{\text{sh}} \simeq ika^2 E_0 (\epsilon^* \cdot \epsilon_0) \frac{J_1(ka \sin \theta)}{(ka \sin \theta)} \quad (9.175)$$

The scattering from the illuminated side of the obstacle cannot be calculated without specifying the shape and nature of the surface. We assume, for purposes of illustration, that the illuminated surface is perfectly conducting. In utilizing (9.139) we must know the tangential components of \mathbf{E}_s and \mathbf{B}_s on S_1 . As mentioned in the introductory paragraphs of this section, in the short wavelength limit these are approximately opposite and equal, respectively, to the corresponding components of the incident fields. Thus the contributions from the illuminated side is

$$\epsilon^* \cdot \mathbf{F}_{\text{ill}} = \frac{E_0}{4\pi i} \int_{\text{ill}} \epsilon^* \cdot [-\mathbf{n}' \times (\mathbf{k}_0 \times \epsilon_0) + \mathbf{k} \times (\mathbf{n}' \times \epsilon_0)] e^{i(\mathbf{k}_0 - \mathbf{k}) \cdot \mathbf{x}'} da' \quad (9.176)$$

Comparison with the shadow contribution (9.171) at the same stage shows a sign difference in the first term. This is crucial in giving very different angular behaviors of the two amplitudes. The counterpart of (9.172) is

$$\epsilon^* \cdot \mathbf{F}_{\text{ill}} = \frac{E_0}{4\pi i} \int_{\text{ill}} \epsilon^* \cdot [(\mathbf{k} - \mathbf{k}_0) \times (\mathbf{n}' \times \epsilon_0) - (\mathbf{n}' \cdot \epsilon_0) \mathbf{k}_0] e^{i(\mathbf{k}_0 - \mathbf{k}) \cdot \mathbf{x}'} da' \quad (9.177)$$

For $kR \gg 1$, the exponential oscillates rapidly as before, but now, in the forward direction, where we anticipate the major contribution to the integral, the other factor in the integrand goes to zero. This can be traced to the presence of $(\mathbf{k} - \mathbf{k}_0)$ in the first term, rather than the $(\mathbf{k} + \mathbf{k}_0)$ of the shadow amplitude (9.172). The illuminated side of the scatterer thus gives only a modest contribution to the scattering at small angles. This makes perfect sense if we think of the limit of geometrical optics. The illuminated side must give the reflected wave, and the reflection is mainly at angles other than forward.

To proceed further we must specify the *shape* of the illuminated portion of the scatterer, as well as its electromagnetic properties. We assume that the surface is spherical of radius a . Since the contribution is not dominantly forward, we must consider arbitrary scattering angles. The integrand in (9.177) consists of a relatively slowly varying vector function of angles times a rapidly varying

exponential. As discussed in Section 7.11(d), the dominant contribution to such an integral comes from the region of integration where the phase of the exponential is stationary. If (θ, ϕ) are the angular coordinates of \mathbf{k} and (α, β) those of \mathbf{n}' , relative to \mathbf{k}_0 , the phase factor is

$$f(\alpha, \beta) = (\mathbf{k}_0 - \mathbf{k}) \cdot \mathbf{x}' = ka[(1 - \cos \theta) \cos \alpha - \sin \theta \sin \alpha \cos(\beta - \phi)] \quad (9.178)$$

The stationary point is easily shown to be at angles α_0, β_0 , where

$$\left. \begin{aligned} \alpha_0 &= \frac{\pi}{2} + \frac{\theta}{2} \\ \beta_0 &= \phi \end{aligned} \right\} \quad (9.179)$$

These angles are evidently just those appropriate for reflection from the sphere according to geometrical optics. At this point the unit vector \mathbf{n}' points in the direction of $(\mathbf{k} - \mathbf{k}_0)$. If we expand the phase factor around $\alpha = \alpha_0, \beta = \beta_0$, we obtain

$$f(\alpha, \beta) = -2ka \sin \frac{\theta}{2} \left[1 - \frac{1}{2} \left(x^2 + \cos^2 \frac{\theta}{2} y^2 \right) + \dots \right] \quad (9.180)$$

where $x = \alpha - \alpha_0, y = \beta - \beta_0$. Then integral (9.177) can be approximated by evaluating the square bracket there at $\alpha = \alpha_0, \beta = \beta_0$:

$$\mathbf{\epsilon}^* \cdot \mathbf{F}_{\text{ill}} \approx \frac{ka^2 E_0}{4\pi i} \sin \theta e^{-2ika \sin(\theta/2)} \mathbf{\epsilon}^* \cdot \mathbf{\epsilon}_r \int dx e^{i[ka \sin(\theta/2)]x^2} \int dy e^{i[ka \sin(\theta/2) \cos^2(\theta/2)]y^2} \quad (9.181)$$

where $\mathbf{\epsilon}_r$ is a unit polarization vector defined by

$$\mathbf{\epsilon}_r = -\mathbf{\epsilon}_0 + 2(\mathbf{n} \cdot \mathbf{\epsilon}_0)\mathbf{n},$$

\mathbf{n} , being a unit vector in the direction of $(\mathbf{k} - \mathbf{k}_0)$. The vector $\mathbf{\epsilon}_r$ is just the polarization expected for reflection, having a component perpendicular to the surface equal to the corresponding component of $\mathbf{\epsilon}_0$ and a component parallel to the surface opposite in sign, as shown in Fig. 9.17. The x and y integrals in (9.181) can be approximated using (7.135) provided $2ka \sin \theta/2 \gg 1$, giving

$$\mathbf{\epsilon}^* \cdot \mathbf{F}_{\text{ill}} \approx E_0 \frac{a}{2} e^{-2ika \sin(\theta/2)} \mathbf{\epsilon}^* \cdot \mathbf{\epsilon}_r \quad (9.182)$$

For $2ka \sin \theta/2$ large, the reflected contribution is constant in magnitude as a function of angle, but it has a rapidly varying phase; as $\theta \rightarrow 0$, it vanishes as θ^2 .

Comparison of the shadow amplitude (9.175) with the reflected amplitude (9.182) shows that in the very forward direction the shadow contribution dominates in magnitude over the reflected amplitude by a factor of $ka \gg 1$, while

Fig. 9.17 Polarization of the reflected wave relative to the incident polarization. \mathbf{n}_r is normal to the surface at the point appropriate for reflection according to geometrical optics. To avoid complexity in the figure, the wave vectors \mathbf{k}_0 and \mathbf{k} are not shown, but they are perpendicular to ϵ_0 and ϵ_r , respectively, and so oriented as to make their difference parallel to \mathbf{n}_r .

at angles where $ka \sin \theta \gg 1$, the ratio of the magnitudes is of the order of $1/(ka \sin^3 \theta)^{1/2}$. Thus, the differential scattering cross section (9.81), summed over the outgoing and averaged over the initial polarization states, is given in the two regions by

$$\frac{d\sigma}{d\Omega} \approx \begin{cases} a^2(ka)^2 \left| \frac{J_1(ka \sin \theta)}{ka \sin \theta} \right|^2, & \theta \lesssim \frac{10}{ka} \\ \frac{a^2}{4}, & \theta \gg \frac{1}{ka} \end{cases} \quad (9.183)$$

The scattering in the forward direction is a typical diffraction pattern with a central maximum and smaller secondary maxima, while at larger angles it is isotropic. At intermediate angles there is some interference between the two amplitudes (9.175) and (9.182), causing the cross section to deviate from the sum of the two terms shown in (9.183). Actually, in the present approximation this interference is very small for $ka \gg 1$. There is more interference in the exact solution, as shown in Fig. 9.18, where the dips below unity are indicative of destructive interference.*

The total scattering cross section is obtained by integrating over all angles. Neglecting the interference terms, we find from (9.183) that the shadow diffraction peak gives a contribution of πa^2 , and so does the isotropic part. The total scattering cross section is thus $2\pi a^2$, one factor of the geometrical projected area coming from direct reflection and the other from the diffraction scattering that must accompany the formation of a shadow behind the obstacle. The latter

* For a linearly polarized wave incident, the amount of interference depends on the orientation of the incident polarization vector relative to the plane of observation containing \mathbf{k} and \mathbf{k}_0 . For ϵ_0 in this plane the interference is much greater than for ϵ_0 perpendicular to it. See King and Wu, Appendix, or Bowman, Senior and Uslenghi, pp. 402–405, for numerous graphs with different values of ka .

Fig. 9.18 Semilogarithmic plot of the scattering cross section for a perfectly conducting sphere as a function of scattering angle, with an unpolarized plane wave incident and $ka=10$. The solid curve is the exact result (King and Wu). The dashed curve is the approximation based on the sum of the amplitudes (9.175) and (9.182).

part of the total cross section can be shown to be independent of the detailed shape of the scatterer in the short-wavelength limit (Problem 9.21). Similarly, for a general scatterer that is “opaque,” the reflected or absorbed part of the total cross section will also be equal to the projected area, although without specifying the properties of the illuminated surface we cannot say how it is divided between scattering and absorption.

9.14 Optical Theorem and Related Matters

A fundamental relation, called the *optical theorem*, connects the total cross section of a scatterer to the imaginary part of the forward scattering amplitude. The theorem follows from very general considerations of the conservation of energy and power flow, and has its counterpart in the quantum-mechanical scattering of particles through the conservation of probability.

To establish the theorem we consider the scattering geometry shown in Fig. 9.11. A plane wave with wave vector \mathbf{k}_0 and fields $(\mathbf{E}_i, \mathbf{B}_i)$ is incident in vacuum on a finite scatterer that lies inside the surface S_1 . The scattered fields $(\mathbf{E}_s, \mathbf{B}_s)$ propagate out from the scatterer and are observed far away in the direction of \mathbf{k} . The total fields at all points in space are, by definition,

$$\mathbf{E} = \mathbf{E}_i + \mathbf{E}_s, \quad \mathbf{B} = \mathbf{B}_i + \mathbf{B}_s$$

The scatterer is, in general, dissipative and absorbs energy from the incident wave. The *absorbed* power can be calculated by integrating the inward-going component of the Poynting vector of the *total* fields over the surface S_1 :

$$P_{\text{abs}} = -\frac{c}{8\pi} \oint_{S_1} \text{Re}(\mathbf{E} \times \mathbf{B}^*) \cdot \mathbf{n}' da' \quad (9.184)$$

The *scattered* power is normally calculated by considering the asymptotic form of the Poynting vector for the scattered fields in the region where these are simple transverse fields falling off as $1/r$. But since there are no sources between S_1 and infinity, the scattered power can equally well be evaluated as an integral over S_1 of the outwardly directed component of the *scattered* Poynting vector:

$$P_{\text{scatt}} = \frac{c}{8\pi} \oint_{S_1} \text{Re}(\mathbf{E}_s \times \mathbf{B}_s^*) \cdot \mathbf{n}' da' \quad (9.185)$$

The total power P taken from the incident wave, either by scattering or absorption, is the sum of (9.184) and (9.185). With some obvious substitutions and rearrangements, the total power can be written

$$P = -\frac{c}{8\pi} \oint_{S_1} \text{Re}[\mathbf{E}_s \times \mathbf{B}_i^* + \mathbf{E}_i^* \times \mathbf{B}_s] \cdot \mathbf{n}' da'$$

With the incident wave written explicitly as

$$\begin{aligned} \mathbf{E}_i &= E_0 \boldsymbol{\epsilon}_0 e^{i\mathbf{k}_0 \cdot \mathbf{x}} \\ \mathbf{B}_i &= \frac{1}{k} \mathbf{k}_0 \times \mathbf{E}_i \end{aligned} \quad (9.186)$$

the total power takes the form,

$$P = \frac{c}{8\pi} \text{Re} \left\{ E_0^* \oint_{S_1} e^{-i\mathbf{k}_0 \cdot \mathbf{x}'} \left[\boldsymbol{\epsilon}_0^* \cdot (\mathbf{n}' \times \mathbf{B}_s) + \boldsymbol{\epsilon}_0^* \cdot \frac{\mathbf{k}_0 \times (\mathbf{n}' \times \mathbf{E}_s)}{k} \right] da' \right\}$$

Comparison with (9.139) for the scattering amplitude shows that the total power is related to the *forward* ($\mathbf{k}=\mathbf{k}_0$, $\epsilon=\epsilon_0$) scattering amplitude according to

$$P = \frac{c}{2k} \operatorname{Im} [E_0^* \epsilon_0^* \cdot \mathbf{F}(\mathbf{k}=\mathbf{k}_0)] \quad (9.187)$$

This is the basic result of the optical theorem, although it is customary to express it in a form that is independent of the magnitude of the incident flux. The *total cross section* σ_t (sometimes called the extinction cross section in optics) is defined as the ratio of the total power P to the incident power per unit area, $c |E_0|^2/8\pi$. Similarly, the *normalized scattering amplitude* \mathbf{f} is defined relative to the amplitude of the incident wave at the origin as

$$\mathbf{f}(\mathbf{k}, \mathbf{k}_0) = \frac{\mathbf{F}(\mathbf{k}, \mathbf{k}_0)}{E_0} \quad (9.188)$$

In terms of σ_t and \mathbf{f} the *optical theorem* reads

$$\sigma_t = \frac{4\pi}{k} \operatorname{Im} [\epsilon_0^* \cdot \mathbf{f}(\mathbf{k}=\mathbf{k}_0)] \quad (9.189)$$

The notation in (9.189) corresponds to the standard quantum-mechanical conventions. For particles with spin the relevant forward scattering amplitude is the one in which none of the particles change their spin state. For electromagnetic radiation (photons) this is indicated by the presence of the amplitude $\epsilon_0^* \cdot \mathbf{f}$ for scattered radiation with the same polarization finally as it was initially.

The optical theorem relates different aspects of the scattering and absorption of electromagnetic waves for a single scatterer. It is also possible to connect the forward scattering amplitude for a single scatterer to the macroscopic electromagnetic properties, namely the dielectric constant, of a medium composed of a large number of scatterers. We will content ourselves with a brief elementary discussion and refer the reader to the literature for more detailed and rigorous treatments.* Consider a plane wave (9.186) incident normally from the left on a thin slab of uniform material composed of N identical scattering centers per unit volume, as shown in Fig. 9.19. The incident wave impinges on the scattering centers, causing each to generate a scattered wave. The coherent sum of the incident wave and of all the scattered waves gives a modified wave to the right of the slab. Comparison of this modified wave at the observation point O with that expected for a wave transmitted through a slab described by a macroscopic dielectric constant $\epsilon(\omega)$ then leads to a relation between ϵ and the scattering amplitude \mathbf{f} .

The thickness and the density of the slab are assumed to be small enough so

* See, for example, the very readable review by M. A. Lax, *Reviews of Modern Physics* **23**, 287 (1951), or M. L. Goldberger and K. M. Watson, *Collision Theory*, Wiley, New York, (1964), Chapter 11, especially pp. 766–775.

Fig. 9.19 A plane wave incident normally on a slab of dielectric of thickness d . The scatterers in the slab give rise to a scattered wave that adds coherently to the incident wave to give a modified wave at the observation point O behind the slab.

that only single scatterings in the slab need be considered and, as a consequence, that the effective exciting field at each scatterer is just the incident field itself. The scattered field produced at the observation point O with cylindrical coordinates $(0, 0, z_0)$ by the $N d^3x$ scatterers in the infinitesimal volume element d^3x at the point $\mathbf{x}(\rho, \phi, z)$ in the slab is, in this approximation,

$$d\mathbf{E}_s = \frac{e^{ikR}}{R} \mathbf{f}(k, \theta, \phi) E_0 e^{ik_0 \cdot \mathbf{x}} N d^3x$$

where we have written the scattering amplitude in terms of the scattering angles θ and ϕ , with $\sin \theta = \rho/R$, and have assumed that the observation point is many wavelengths from the slab. The distance from the volume element to O is $R = [\rho^2 + (z_0 - z)^2]^{1/2}$. The presence of the phase factor of the incident wave is necessary to account for the location of the scatterers at \mathbf{x} , rather than at the origin of coordinates. The total scattered field is obtained by integration over the volume of the slab:

$$\mathbf{E}_s = NE_0 \int_0^{2\pi} d\phi \int_0^d dz e^{ikz} \int_0^\infty \rho d\rho \frac{e^{ikR}}{R} \mathbf{f}(k, \theta, \phi) \quad (9.190)$$

Since $\rho d\rho = R dR$, this expression can be written

$$\mathbf{E}_s = NE_0 \int_0^{2\pi} d\phi \int_0^d dz e^{ikz} \int_{|z_0-z|}^\infty dR e^{ikR} \mathbf{f}(k, \theta, \phi) \quad (9.191)$$

where $\cos \theta = (z_0 - z)/R$. We now treat $e^{ikR} dR$ as a differential and integrate by

parts to obtain for the R -integration,

$$\int_{|z_0-z|}^{\infty} dR e^{ikR} \mathbf{f}(k, \theta, \phi) \\ = \frac{1}{ik} e^{ikR} \mathbf{f}(k, \theta, \phi) \Big|_{R=|z_0-z|}^{\infty} + \frac{1}{ik} \int_{|z_0-z|}^{\infty} dR \left(\frac{z_0-z}{R^2} \right) e^{ikR} \frac{d}{d(\cos \theta)} \mathbf{f}(k, \theta, \phi)$$

Provided the indicated derivative of \mathbf{f} is well-behaved, the remaining integral is of the order of $1/(k|z_0-z|)$ times the original. Since we have assumed that the observation point is many wavelengths from the slab, this integral can be neglected. Neglecting the oscillating contribution at the upper limit $R \rightarrow \infty$ (this can be made to vanish somewhat more plausibly by assuming that the number N of scattering centers per unit volume falls to zero at very large ρ), we have the result

$$\int_{|z_0-z|}^{\infty} dR e^{ikR} \mathbf{f}(k, \theta, \phi) = \frac{i}{k} e^{ik|z_0-z|} \mathbf{f}(k, 0)$$

The scattered field at O is therefore

$$\mathbf{E}_s = \frac{2\pi i}{k} N E_0 \mathbf{f}(k, 0) \int_0^d dz e^{ik[z+|z_0-z|]}$$

Since $z_0 > z$ by assumption, we have finally

$$\mathbf{E}_s = \frac{2\pi i}{k} N E_0 \mathbf{f}(k, 0) e^{ikz_0} d \quad (9.192)$$

The *total* electric field at the observation point O is

$$\mathbf{E} = E_0 e^{ikz_0} \left[\epsilon_0 + \frac{2\pi i N d}{k} \mathbf{f}(k, 0) \right] \quad (9.193)$$

correct to first order in the slab thickness d . The amplitude at O for a wave with the same polarization state as the incident wave is

$$\epsilon_0^* \cdot \mathbf{E} = E_0 e^{ikz_0} \left[1 + \frac{2\pi i N d}{k} \epsilon_0^* \cdot \mathbf{f}(k, 0) \right] \quad (9.194)$$

Suppose that we now consider the slab macroscopically, with its electromagnetic properties specified by a dielectric constant $\epsilon(\omega)$ appropriate to describe the propagation of the wave of frequency $\omega = ck$ and polarization ϵ_0 . A simple calculation using the formulas of Chapter 7 shows that the transmitted wave at $z = z_0$ is given by

$$\epsilon_0^* \cdot \mathbf{E}(\text{macroscopic}) = E_0 e^{ikz_0} \left[1 + ik(\epsilon - 1) \frac{d}{2} \right] \quad (9.195)$$

correct to first order in d , but with no approximation concerning the smallness of $|\epsilon - 1|$. Comparison of (9.194) and (9.195) shows that the dielectric constant can

be written in terms of the forward scattering amplitude as

$$\epsilon(\omega) = 1 + \frac{4\pi N}{k^2} \epsilon_0^* \cdot \mathbf{f}(k, 0) \quad (9.196)$$

A number of observations are in order. It is obvious that our derivation has been merely indicative, with a number of simplifying assumptions and the notion of a macroscopic description assumed rather than derived. More careful considerations show that the scattering amplitude in (9.196) should be evaluated at the wave number k' in the medium, not at the free-space wave number k , and that there is a multiplier to the second term that gives a measure of the effective exciting field at a scatterer relative to the total coherent field in the medium. The reader can consult the literature cited above for these and other details. Suffice it to say that (9.196) is a reasonable approximation for not too dense substances and provided correlations among neighboring scatterers are not important. It is worthwhile to illustrate (9.196) with the simple electronic oscillator model used in Chapter 7 to describe the dielectric constant. The dipole moment of the atom is given by (7.50), summed over the various oscillators:

$$\mathbf{p} = \frac{e^2}{m} \sum_j f_j (\omega_j^2 - \omega^2 - i\omega\gamma_j)^{-1} E_0 \epsilon_0 \quad (9.197)$$

From (9.80) we infer that the atomic scattering amplitude is

$$\mathbf{f}(\mathbf{k}) = \frac{e^2}{m} \sum_j f_j (\omega_j^2 - \omega^2 - i\omega\gamma_j)^{-1} (\mathbf{k} \times \epsilon_0) \times \mathbf{k} \quad (9.198)$$

The scalar product of ϵ_0^* with the forward scattering amplitude is then

$$\epsilon_0^* \cdot \mathbf{f}(\mathbf{k} = \mathbf{k}_0) = \frac{e^2 k^2}{m} \sum_j f_j (\omega_j^2 - \omega^2 - i\omega\gamma_j)^{-1}$$

Substitution into (9.196) yields the index of refraction

$$\epsilon(\omega) = 1 + \frac{4\pi N e^2}{m} \sum_j f_j (\omega_j^2 - \omega^2 - i\omega\gamma_j)^{-1} \quad (9.199)$$

in agreement with (7.51).

Contact can be established between (9.196) and the optical theorem (9.189) by recalling that the attenuation coefficient α is related to the total cross section of a single scatterer through $\alpha = N\sigma_t$ and to the imaginary part of the wave number in the medium through $\alpha = 2 \operatorname{Im}(k')$. From (9.196) and the relations (7.54) for the real and imaginary parts of k' in term of $\epsilon(\omega)$ we find

$$\alpha = N\sigma_t = \frac{4\pi N}{\operatorname{Re}(k')} \operatorname{Im} [\epsilon_0^* \cdot \mathbf{f}(\operatorname{Re}(k'), 0)] \quad (9.200)$$

where I have improved (9.196) by evaluating \mathbf{f} at the wave number in the medium, as described above. Equation (9.200) indicates that, if we consider scattering by a single scatterer imbedded in a medium, the optical theorem and other relations will appear as before, provided we describe the “kinematics” correctly by using the local wave number k' in the medium. The same situation holds in the scattering of electrons in a solid, for example, where the effective mass or other approximation is used to take into account propagation through the lattice.

As a final comment on the optical theorem we note the problem of approximations for \mathbf{f} . The optical theorem is an exact relation. If an approximate expression for \mathbf{f} is employed, a manifestly wrong result for the total cross section may be obtained. For example, in the long wavelength limit we find from (9.80) and (9.83) that the scattering amplitude for a dielectric sphere of radius a is

$$\mathbf{f} = \left(\frac{\epsilon - 1}{\epsilon + 2} \right) a^3 (\mathbf{k} \times \boldsymbol{\epsilon}_0) \times \mathbf{k}$$

The forward amplitude is

$$\boldsymbol{\epsilon}_0^* \cdot \mathbf{f}(\mathbf{k} = \mathbf{k}_0) = k^2 a^3 \left(\frac{\epsilon - 1}{\epsilon + 2} \right) \quad (9.201)$$

For a lossless dielectric, this amplitude is real; the optical theorem (9.189) then yields $\sigma_t = 0$. On the other hand, we know that the total cross section is in this case equal to the scattering cross section (9.89):

$$\sigma_{sc} = \frac{8\pi}{3} k^4 a^6 \left| \frac{\epsilon - 1}{\epsilon + 2} \right|^2 \quad (9.202)$$

Even with a lossy dielectric ($\text{Im } \epsilon \neq 0$), the optical theorem yields a total cross section,

$$\sigma_t = \frac{12\pi k a^3 \text{Im } \epsilon}{|\epsilon + 2|^2} \quad (9.203)$$

while the scattering cross section remains (9.202). These seeming contradictions are reflections of the necessity of different orders of approximation required to obtain consistency between the two sides of the optical theorem. In the long wavelength limit it is necessary to evaluate the forward scattering amplitude to higher order in powers of ω to find the scattering cross section contribution in the total cross section by means of the optical theorem. For lossless or nearly lossless scatterers it is therefore simplest to determine the total cross section directly by integration of the differential scattering cross section over angles. For dissipative scatterers, on the other hand, the optical theorem yields a nonzero answer that has a different (usually a lower power) dependence on ω and other parameters from that of the scattering cross section. This contribution is, of course, the *absorption* cross section to lowest explicit order in ω . It can be

calculated from first principles with (9.184), but the optical theorem provides an elegant and convenient method. Examples of these considerations are given in the problems at the end of the chapter. An analogous situation occurs in quantum-mechanical scattering by a real potential where the first Born approximation yields a real scattering amplitude. The second Born approximation has an imaginary part in the forward direction that gives, via the optical theorem, a total cross section in agreement with the integrated scattering cross section of the first Born approximation.

The simple theory of radiation from a localized source distribution is discussed in all modern textbooks. Treatments analogous to that given here may be found in

Panofsky and Phillips, Chapter 13,

Smythe, Chapter 12

Stratton, Chapter 8.

More complete discussions of antennas and antenna arrays are given in applied works, such as

Jordan and Balmain,

Kraus,

Schelkunoff and Friis,

Silver.

Treatments of antennas as boundary-value problems from various points of view can be found in

Hallén,

Jones,

Schelkunoff, *Advanced Antenna Theory*.

The subject of excitation of wave guides by localized sources and the use of multipole moments is discussed by

Collin.

The original literature on the description of small apertures (Bethe holes) in terms of effective dipole moments has been cited in Section 9.5. The basic theory and some applications appear in

Collin,

Montgomery, Dicke and Purcell, pp. 176 ff and pp. 296 ff,

Van Bladel.

The subject of diffraction has a very extensive literature. A comprehensive treatment of both scalar Kirchhoff and vector theory, with many examples and excellent figures, is given by

Born and Wolf, Chapters VIII, IX, and XI.

The review,

C. J. Bouwkamp, *Diffraction Theory*, in *Reports on Progress in Physics*, ed. A. C.

Stickland, Vol. XVII, pp. 35–100, The Physical Society, London (1954),

has an extensive list of references and treats a number of difficult points. More elementary discussions of the scalar theory are found in

Slater and Frank, Chapters XIII and XIV,

Sommerfeld, *Optics*,

Stone, Chapters 8, 9 and 10.

Sommerfeld also discusses his rigorous calculation of diffraction by a straight edge, one of the few exact solutions in diffraction theory.

The language of diffraction is used increasingly in optical applications, such as Abbé's theory of the resolution of optical instruments and the phase-contrast microscope. An introduction to this area from an electrical engineering viewpoint is provided by

J. W. Goodman, *Introduction to Fourier Optics*, McGraw-Hill, New York (1968).

Born and Wolf and also Stone discuss some aspects of these applications.

A most interesting approximate treatment of scattering, made possible by high-speed computing methods, is described by

E. M. Purcell and C. R. Pennypacker, *Astrophys. J.* **186**, 705 (1973).

A dielectric scatterer of arbitrary shape is approximated by a simple cubic lattice array of dipoles, roughly 100 in number, each with its dipole fields (9.18). A self-consistent scattering solution is sought by iteration. Comparison with exact calculations for spheres shows good agreement in the interesting range of wavelengths ($kR \sim 0.5-5$). The method has application to scattering and absorption of light by interstellar grains.

PROBLEMS

9.1 A common textbook example of a radiating system (see Problem 9.2) is a configuration of charges fixed relative to each other but in rotation. The charge density is obviously a function of time, but it is not in the form of (9.1).

(a) Show that for rotating charges one alternative is to calculate *real* time-dependent multipole moments using $\rho(\mathbf{x}, t)$ directly and then compute the multipole

moments for a given harmonic frequency with the convention of (9.1) by inspection or Fourier decomposition of the time-dependent moments. Note that care must be taken when calculating $q_{lm}(t)$ to form linear combinations that are real before making the connection.

(b) Consider a charge density $\rho(\mathbf{x}, t)$ that is periodic in time with period $T = 2\pi/\omega_0$. By making a Fourier series expansion, show that it can be written as

$$\rho(\mathbf{x}, t) = \rho_0(\mathbf{x}) + \sum_{n=1}^{\infty} \operatorname{Re} [2\rho_n(\mathbf{x})e^{-in\omega_0 t}]$$

where

$$\rho_n(\mathbf{x}) = \frac{1}{T} \int_0^T \rho(\mathbf{x}, t) e^{in\omega_0 t} dt$$

This shows explicitly how to establish connection with (9.1).

(c) For a single charge q rotating about the origin in the x - y plane in a circle of radius R at constant angular speed ω_0 , calculate the $l=0$ and $l=1$ multipole moments by the two methods, (a) and (b), and compare. In method (b) express the charge density $\rho_n(\mathbf{x})$ in cylindrical coordinates. Are there higher multipoles, for example, quadrupole? At what frequencies?

9.2 A radiating quadrupole consists of a square of side a with charges $\pm q$ at alternate corners. The square rotates with angular velocity ω about an axis normal to the plane of the square and through its center. Calculate the quadrupole moments, the radiation fields, the angular distribution of radiation, and the total radiated power, all in the long-wavelength approximation.

9.3 Two halves of a spherical metallic shell of radius R and infinite conductivity are separated by a very small insulating gap. An alternating potential is applied between the two halves of the sphere so that the potentials are $\pm V \cos \omega t$. In the long-wavelength limit, find the radiation fields, the angular distribution of radiated power, and the total radiated power from the sphere.

9.4 The transitional charge density for the radiative transition from the $m=0$ $2p$ state in hydrogen to the $1s$ ground state is, in the notation of (9.1),

$$\rho(r, \theta, \phi, t) = \frac{2e}{\sqrt{6}} a_0^{-4} \cdot r e^{-3r/2a_0} Y_{00} Y_{10} e^{-i\omega_0 t}$$

where $a_0 = \hbar^2/me^2$ is the Bohr radius and $\omega_0 = 3e^2/8\hbar a_0$ is the frequency difference of the levels.

(a) Evaluate all the radiation multipoles for this charge density in the long wavelength limit.

(b) In the electric dipole approximation calculate the total time-averaged power radiated. Express your answer in units of $(\hbar\omega_0) \cdot (\alpha^4 c/a_0)$, where $\alpha = e^2/\hbar c$ is the fine-structure constant.

(c) Interpreting the classically calculated power as the photon energy ($\hbar\omega_0$) times the transition probability, evaluate numerically the transition probability in units of sec^{-1} .

(d) If, instead of the semiclassical charge density used above, the electron in the $2p$ state was described by a circular Bohr orbit of radius $2a_0$, rotating with the transitional frequency ω_0 , what would the radiated power be? Express your answer in the same units as in (b) and evaluate the ratio of the two powers numerically.

- 9.5 A thin linear antenna of length d is excited in such a way that the sinusoidal current makes a full wavelength of oscillation as shown in the figure.

Problem 9.5

- (a) Calculate exactly the power radiated per unit solid angle and plot the angular distribution of radiation.
 - (b) Determine the total power radiated and find a numerical value for the radiation resistance.
- 9.6 Treat the linear antenna of Problem 9.5 by the long-wavelength multipole expansion method.
- (a) Calculate the multipole moments (electric dipole, magnetic dipole, and electric quadrupole).
 - (b) Compare the shape of the angular distribution of radiated power for the lowest nonvanishing multipole with the exact distribution of Problem 9.5.
 - (c) Determine the total power radiated for the lowest multipole and the corresponding radiation resistance. Compare with 9.5(b). Is there a paradox here?
- 9.7 A qualitative understanding of the result for the reactance of a short antenna whose radiation fields are described by the electric dipole fields of Section 9.2 can be achieved by considering the idealized dipole fields (9.18).
- (a) Show that the integral over all angles at fixed distance r of $|\mathbf{E}|^2 - |\mathbf{B}|^2$ is

$$\int [|\mathbf{E}|^2 - |\mathbf{B}|^2] d\Omega = 8\pi \frac{|\mathbf{p}|^2}{r^6}$$

- (b) Using (6.140) for the reactance, show that the contribution X_a to the reactance from fields at distances $r > a$ is

$$X_a = -\frac{2\omega}{3} \frac{|\mathbf{p}|^2}{|I_i|^2 a^3}$$

where I_i is the input current.

- (c) For the short center-fed antenna of Section 9.2 show that $X_a = -d^2/6\omega a^3$, corresponding to an effective capacitance $6a^3/d^2$. With $a = d/2$, X_a gives only a small fraction of the total negative reactance of a short antenna. The fields close to the antenna, obviously not dipole in character, contribute heavily. For calculations of reactances of short antennas, see the book by *Schelkunoff and Friis*.
- 9.8 Consider the excitation of a wave guide in Problem 8.10 from the point of view of multipole moments of the source.
- (a) For the linear probe antenna calculate the multipole moment components of \mathbf{p} , \mathbf{m} , $Q_{\alpha\beta}$, $Q_{\alpha\beta}^M$ that enter (9.69).
 - (b) Calculate the amplitudes for excitation of the $TE_{1,0}$ mode and evaluate the power flow. Compare the multipole expansion result with the answer given in Problem 8.10(b). Discuss the reasons for agreement or disagreement. What about the comparison for excitation of other modes?

- 9.9 (a) Verify by direct calculation that the *static* tangential electric field (3.185) in a circular opening in a flat conducting plane, when inserted into the defining equation (9.72) for the electric dipole moment \mathbf{p}_{eff} , leads to the expression (9.77).
 (b) Determine the value of $i\omega \mathbf{m}_{\text{eff}}/c$ given by (9.72) with the static electric field in (a).
 (c) Use the *static* normal magnetic field (5.132) for the corresponding magnetic boundary problem with a circular opening to compute via (9.76) the magnetic dipole moment \mathbf{m}_{eff} and compare with (9.77).
 (d) Comment on the differences between the results of (b) and (c) and the use of the definitions (9.72) in a consistent fashion. [See Section 9 of the article, Diffraction Theory, by C. J. B. Bouwkamp in *Reports on Progress in Physics*, Vol. 17, ed. A. C. Stickland, The Physical Society, London, 1954.]
- 9.10 An ideal rectangular wave guide of dimensions (a, b) , $(a > b)$, and having $\mu = \epsilon = 1$ in its interior, has an obstacle in the form of a perfectly conducting flat plate of negligible thickness at $z=0$, with a *small* circular hole of radius R whose center has coordinates (x_0, y_0) . A wave of the lowest mode ($\text{TE}_{1,0}$) is incident on the obstacle from the region $z < 0$. Show that the transmitted wave of the lowest mode has a relative amplitude given approximately by

$$T \approx -i \frac{16}{3} \frac{kR^3}{ab} \sin^2 \left(\frac{\pi x_0}{a} \right)$$

where k is the wave number of the $\text{TE}_{1,0}$ mode in the guide. What is the equivalent relative shunt impedance (Z/Z_0) of this obstacle? Is it inductive or capacitive?

- 9.11 The rectangular wave guide of the previous problem, instead of having a transverse plate at $z=0$, has a small circular hole of radius R cut in its narrow (side) wall. Show that the effective relative shunt admittance [defined by (8.151)] of the hole to the transmission of the $\text{TE}_{1,0}$ mode is approximately

$$Y_d \approx -i \frac{8\pi^2 R^3}{3kba^3}$$

- 9.12 A rectangular wave guide of dimensions a, b ($a > b$) has a *small* circular hole of radius R cut in the center of its top (broad) wall at $x = a/2, y = b, z = 0$. The frequency is such that only the $\text{TE}_{1,0}$ mode can propagate. A wave is incident from $z = -\infty$, propagating towards $z = +\infty$. The medium inside the guide has $\mu = \epsilon = 1$.
 (a) Show that, as seen from inside the guide, the hole acts as a superposition of electric and magnetic dipoles with nonvanishing components,

$$p_y = -\frac{R^3}{3\pi} E_y, \quad m_x = -\frac{2R^3}{3\pi Z} E_y$$

where Z is the wave impedance of the $\text{TE}_{1,0}$ mode and E_y its electric field evaluated at the hole ($E_y = (2/ab)^{1/2}$ for a wave of unit amplitude in the convention of Section 8.11).

- (b) Calculate the reflection and transmission coefficients for the incident wave. If possible, find an operating frequency such that there is no reflected wave or no additional transmitted wave.
- 9.13 The wave guide of Problem 9.12 is coupled to another identical guide with a similar centered hole in it by placing the guides on top of each other with the holes coincident, but the axes of the guides make an angle θ with each other as shown in the figure. Again a wave of unit amplitude is incident from the left in the bottom guide. Wall thickness can be neglected.

Problem 9.13

(a) Show that the amplitudes of the waves propagating in the positive and negative directions in the top guide are proportional to

$$1 \pm 2 \left(1 - \frac{\omega_1^2}{\omega^2} \right) \cos \theta$$

where $\omega_1 = \pi c/a$ is the cutoff frequency of the guide. Determine which sign goes with which amplitude.

(b) Determine the proportionality constant by which to multiply the expression in (a) to obtain the amplitudes in the top guide. For a wave guide with $b = a/2$, $\omega = \sqrt{2}\omega_1$, and the angle θ chosen to suppress completely the transmission in one direction (which direction?), calculate the value of R/a such that the coupling factor is 20 db (i.e., one per cent of the power incident in the lower guide is transmitted in the upper guide). Is the approximation $R/a \ll 1$ a good one for this magnitude of coupling?

The coupling device of this problem is called the Bethe hole directional coupler, after H. A. Bethe who developed its principles in 1943.

9.14 In the scattering of light by a gas very near the critical point the scattered light is observed to be “whiter,” that is, its spectrum is less predominantly peaked toward the blue, than far from the critical point. Show that this can be understood by the fact the volumes of the density fluctuations become large enough that Rayleigh’s law fails to hold. In particular, consider the lowest order approximation to the scattering by a uniform dielectric sphere of radius a whose dielectric constant ϵ differs only slightly from unity.

(a) Show that for $ka \gg 1$, the differential cross section is sharply peaked in the forward direction and the total scattering cross section is approximately

$$\sigma \approx \frac{\pi}{2} (ka)^2 |\epsilon - 1|^2 a^2$$

with a k^2 , rather than k^4 , dependence on frequency.

(b) Show that for arbitrary ka the total cross section to lowest order in $(\epsilon - 1)$ is the

expression given in (a), multiplied by the function,

$$F(z) = 1 + 5z^{-2} - \frac{7}{2}z^{-4}(1 - \cos 2z) - z^{-3} \sin 2z - 4(z^{-2} - z^{-4}) \int_0^{2z} \frac{1 - \cos t}{t} dt$$

where $z = 2ka$. [This result is due to Lord Rayleigh, 1914.]

- 9.15** The aperture or apertures in a perfectly conducting plane screen can be viewed as the location of effective sources that produce radiation (the diffracted fields). An aperture whose dimensions are small compared with a wavelength acts as a source of dipole radiation with the contributions of other multipoles being negligible.

(a) Beginning with (9.147) show that the effective electric and magnetic dipole moments can be expressed in terms of integrals of the tangential electric field in the aperture as follows:

$$\begin{aligned} \mathbf{p} &= \frac{\epsilon \mathbf{n}}{4\pi} \int (\mathbf{x} \cdot \mathbf{E}_{\text{tan}}) da \\ \mathbf{m} &= \frac{c}{2\pi i \omega \mu} \int (\mathbf{n} \times \mathbf{E}_{\text{tan}}) da \end{aligned} \quad (9.72)$$

where \mathbf{E}_{tan} is the *exact* tangential electric field in the aperture, \mathbf{n} is the normal to the plane screen, directed into the region of interest, and the integration is over the area of the openings.

(b) Show that the expression for the magnetic moment can be transformed into

$$\mathbf{m} = \frac{1}{2\pi\mu} \int \mathbf{x}(\mathbf{n} \cdot \mathbf{B}) da \quad (9.76)$$

Be careful about possible contributions from the edge of the aperture where some components of the fields are singular if the screen is infinitesimally thick.

- 9.16** A perfectly conducting flat screen occupies one-half of the x - y plane (i.e., $x < 0$). A plane wave of intensity I_0 and wave number k is incident along the z axis from the region $z < 0$. Discuss the values of the diffracted fields in the plane parallel to the x - y plane defined by $z = Z > 0$. Let the coordinates of the observation point be $(X, 0, Z)$.

(a) Show that, for the usual scalar Kirchhoff approximation and in the limit $Z \gg X$ and $\sqrt{kZ} \gg 1$, the diffracted field is

$$\psi(X, 0, Z, t) \approx I_0^{1/2} e^{ikZ - i\omega t} \left(\frac{1+i}{2i} \right) \sqrt{\frac{2}{\pi}} \int_{-\xi}^{\infty} e^{it^2} dt$$

where $\xi = (k/2Z)^{1/2} X$.

(b) Show that the intensity can be written

$$I = |\psi|^2 = \frac{I_0}{2} \left[(C(\xi) + \frac{1}{2})^2 + (S(\xi) + \frac{1}{2})^2 \right]$$

where $C(\xi)$ and $S(\xi)$ are the so-called Fresnel integrals. Determine the asymptotic behavior of I for ξ large and positive (illuminated region) and ξ large and negative (shadow region). What is the value of I at $X = 0$? Make a sketch of I as a function of X for fixed Z .

(c) Use the vector formula (9.147) to obtain a result equivalent to that of part (a). Compare the two expressions.

- 9.17** A linearly polarized plane wave of amplitude E_0 and wave number k is incident on a circular opening of radius a in an otherwise perfectly conducting flat screen. The

incident wave vector makes an angle α with the normal to the screen. The polarization vector is perpendicular to the plane of incidence.

(a) Calculate the diffracted fields and the power per unit solid angle transmitted through the opening, using the vector Smythe-Kirchhoff formula (9.147) with the assumption that the tangential electric field in the opening is the unperturbed incident field.

(b) Compare your result in part (a) with the standard scalar Kirchhoff approximation and with the result in Section 9.12 for the polarization vector in the plane of incidence.

9.18 Discuss the diffraction of a plane wave by a circular hole of radius a , following Section 9.12, but using a vector Kirchhoff approximation based on (9.136) instead of the Smythe formula (9.147).

(a) Show that the diffracted electric field in this approximation differs from (9.159) in two ways, first, that $\cos \alpha$ is replaced by $(\cos \theta + \cos \alpha)/2$, and second, by the addition of a term proportional to $(\mathbf{k} \times \mathbf{e}_3)$. Compare with the obliquity factors \mathcal{O} of the scalar theory.

(b) Evaluate the ratio of the scattered power for this vector Kirchhoff approximation to that of (9.162) for the conditions shown in Fig. 9.16. Sketch the two angular distributions.

9.19 A rectangular opening with sides of length a and $b \geq a$ defined by $x = \pm(a/2)$, $y = \pm(b/2)$ exists in a flat, perfectly conducting plane sheet filling the x - y plane. A plane wave is normally incident with its polarization vector, making an angle β with the long edges of the opening.

(a) Calculate the diffracted fields and power per unit solid angle with the vector Smythe-Kirchhoff relation (9.156), assuming that the tangential electric field in the opening is the incident unperturbed field.

(b) Calculate the corresponding result of the scalar Kirchhoff approximation.

(c) For $b = a$, $\beta = 45^\circ$, $ka = 4\pi$, compute the vector and scalar approximations to the diffracted power per unit solid angle as a function of the angle θ for $\phi = 0$. Plot a graph showing a comparison between the two results.

9.20 A cylindrical coaxial transmission line of inner radius a and outer radius b has its axis along the negative z axis. Both inner and outer conductors end at $z = 0$, and the outer one is connected to an infinite plane copper flange occupying the whole x - y plane (except for the annulus of inner radius a and outer radius b around the origin). The transmission line is excited at frequency ω in its dominant TEM mode, with the peak voltage between the cylinders being V . Use the vector Smythe-Kirchhoff approximation to discuss the radiated fields, the angular distribution of radiation, and the total power radiated.

9.21 (a) Show from (9.173) that the integral of the shadow scattering differential cross section, summed over outgoing polarizations, can be written in the short-wavelength limit as

$$\sigma_{\text{sh}} = \int d^2x_{\perp} \int d^2x'_{\perp} \cdot \frac{1}{4\pi^2} \int e^{i(\mathbf{x}_{\perp} - \mathbf{x}'_{\perp}) \cdot \mathbf{k}_{\perp}} d^2k_{\perp}$$

and therefore that σ_{sh} is equal to the projected area of the scatterer, independent of its detailed shape.

(b) Apply the optical theorem to the “shadow” amplitude (9.173) to obtain the total cross section under the assumption that in the forward direction the contribution from the illuminated side of the scatterer is negligible in comparison.

- 9.22 (a) Using the approximate amplitudes of Section 9.13, show that, for a linearly polarized plane wave of wave number k incident on a perfectly conducting sphere of radius a in the limit of large ka , the differential scattering cross section in the E -plane (ϵ_0 , \mathbf{k}_0 , and \mathbf{k} coplanar) is

$$\frac{d\sigma}{d\Omega} (E\text{-plane}) = \frac{a^2}{4} \left[4 \cot^2 \theta J_1^2(ka \sin \theta) + 1 - 4 \cot \theta J_1(ka \sin \theta) \sin \left(2 ka \sin \frac{\theta}{2} \right) \right]$$

and in the H -plane (ϵ_0 perpendicular to \mathbf{k}_0 and \mathbf{k}) is

$$\frac{d\sigma}{d\Omega} (H\text{-plane}) = \frac{a^2}{4} \left[4 \operatorname{cosec}^2 \theta J_1^2(ka \sin \theta) + 1 + 4 \operatorname{cosec} \theta J_1(ka \sin \theta) \sin \left(2 ka \sin \frac{\theta}{2} \right) \right]$$

(The dashed curve in Fig. 9.18 is the average of these two expressions.)

(b) Look up the exact calculations in *King and Wu*, Appendix, or *Bowman, Senior, and Uslenghi*, pp. 402–405. Are the qualitative aspects of the interference between the diffractive and reflective amplitudes exhibited in part (a) in agreement with the exact results? What about quantitative agreement?

- 9.23 Discuss the diffraction due to a small, circular hole of radius a in a flat, perfectly conducting sheet, assuming that $ka \ll 1$.

(a) If the fields near the screen on the incident side are normal $\mathbf{E}_0 e^{-i\omega t}$ and tangential $\mathbf{B}_0 e^{-i\omega t}$, show that the diffracted electric field in the Fraunhofer zone is

$$\mathbf{E} = \frac{e^{ikr-i\omega t}}{3\pi r} k^2 a^3 \left[2 \frac{\mathbf{k}}{k} \times \mathbf{B}_0 + \frac{\mathbf{k}}{k} \times \left(\mathbf{E}_0 \times \frac{\mathbf{k}}{k} \right) \right]$$

where \mathbf{k} is the wave vector in the direction of observation.

(b) Determine the angular distribution of the diffracted radiation and show that the total power transmitted through the hole is

$$P = \frac{c}{54\pi^2} k^4 a^6 (4B_0^2 + E_0^2)$$

- 9.24 Specialize the discussion of Problem 9.23 to the diffraction of a plane wave by the small, circular hole. Treat the general case of oblique incidence at an angle α to the normal, with polarization in and perpendicular to the plane of incidence.

(a) Calculate the angular distributions of the diffracted radiation and compare them to the vector Smythe-Kirchhoff approximation results of Section 9.12 and Problem 9.17 in the limit $ka \ll 1$.

(b) For the conditions of Fig. 9.16 (but for $ka \ll 1$) compute the diffraction intensity in the plane of incidence and compare the relative values with the solid curve in Fig. 9.16. (Use a protractor and a ruler to read off the values from Fig. 9.16 at several angles.)

(c) Show that the transmission coefficient [defined above (9.164)] for the two states of polarization are

$$T_{\parallel} = \frac{64}{27\pi^2} (ka)^4 \left(\frac{4 + \sin^2 \alpha}{4 \cos \alpha} \right)$$

$$T_{\perp} = \frac{64}{27\pi^2} (ka)^4 \cos \alpha$$

Note that these transmission coefficients are a factor $(ka)^2$ smaller than those given by the vector Smythe-Kirchhoff approximation in the same limit.

9.25 A solid uniform sphere of radius R and conductivity σ acts as a scatterer of radiation of frequency ω . The wavelength λ is much larger than R and the conductivity is large enough that the skin depth δ at this frequency is small compared to R . An unpolarized beam of radiation is incident on the sphere.

(a) Calculate the absorption cross section of the sphere, defined as the total power absorbed by the sphere compared to the incident power per unit area. Show that it varies as $(\omega)^{1/2}$ provided the conductivity is independent of frequency.

(b) Compare the absorption cross section of (a) with the scattering cross section, calculated to zeroth order in δ/R . Show that the ratio is

$$\frac{\sigma_{sc}}{\sigma_{abs}} \approx \frac{10}{9} \sqrt{2\pi\sigma} \frac{R^4}{c^4} \omega^{7/2}$$

9.26 An unpolarized plane wave of frequency $\omega = ck$ is scattered by a *slightly* lossy uniform isotropic dielectric sphere of radius R much smaller than a wavelength. The sphere is characterized by an ordinary real dielectric constant ϵ and a real conductivity σ . The parameters are such that the skin depth δ is very *large* compared to the radius R .

(a) Calculate the differential and total scattering cross sections.

(b) Show that the absorption cross section is

$$\sigma_{abs} = 48\pi^2 R^2 \frac{(R\sigma/c)}{(\epsilon+2)^2 + (4\pi\sigma/\omega)^2}$$

(c) From part (a) write down the forward scattering amplitude and use the optical theorem to evaluate the total cross section. Compare your answer with the sum of the scattering and absorption cross sections from (a) and (b). Comment.

9.27 The scattering by the dielectric sphere of Problem 9.26 was treated as purely electric dipole scattering. This is adequate unless it happens that the real dielectric constant ϵ is very large. In these circumstances it is possible that a magnetic dipole contribution, even though higher order in kR , can be important.

(a) Show that the changing magnetic flux of the incident wave induces an azimuthal current flow in the sphere and produces a magnetic dipole moment,

$$\mathbf{m} = \frac{i4\pi\sigma}{\omega} (kR)^2 \frac{R^3}{30} \mathbf{B}_{inc}$$

(b) Show that application of the optical theorem to the coherent sum of the electric and magnetic dipole contributions leads to a total cross section,

$$\sigma_t = 48\pi^2 R^2 (R\sigma/c) \cdot \left[\frac{1}{(\epsilon+2)^2 + (4\pi\sigma/\omega)^2} + \frac{1}{90} (kR)^2 \right]$$

(compare Landau and Lifshitz, *Electrodynamics of Continuous Media*, p. 304).

Magnetohydrodynamics and Plasma Physics

10.1 Introduction and Definitions

Magnetohydrodynamics and plasma physics both deal with the behavior of the combined system of electromagnetic fields and a conducting liquid or gas. Conduction occurs when there are free or quasi-free electrons which can move under the action of applied fields. In a solid conductor, the electrons are actually bound, but can move considerable distances on the atomic scale within the crystal lattice before making collisions. Dynamical effects such as conduction and Hall effect are observed when fields are applied to the solid conductor, but mass motion does not in general occur. The effects of the applied fields on the atoms themselves are taken up as stresses in the lattice structure. For a fluid, on the other hand, the fields act on both electrons and ionized atoms to produce dynamical effects, including bulk motion of the medium itself. This mass motion in turn produces modifications in the electromagnetic fields. Consequently we must deal with a complicated coupled system of matter and fields.

The distinction between magnetohydrodynamics and the physics of plasmas is not a sharp one. Nevertheless there are clearly separated domains in which the ideas and concepts of only one or the other are applicable. One way of seeing the distinction is to look at the way in which the relation $\mathbf{J} = \sigma \mathbf{E}$ is established for a conducting substance. In the simple model of Drude the electrons are imagined to be accelerated by the applied fields, but to be altered in direction by collisions, so that their motion in the direction of the field is opposed by an effective frictional force $\nu \mathbf{m} \mathbf{v}$, where ν is an effective collision frequency. Ohm's law just represents a balance between the applied force and the frictional drag. When the frequency of the applied fields is comparable to ν , the electrons have time to accelerate and decelerate between collisions. Then inertial effects enter and the conductivity becomes complex. Unfortunately at these same frequencies the

description of collisions in terms of a frictional force tends to lose its validity. The whole process becomes more complicated. At frequencies well above the collision frequency another thing happens. The electrons and ions are accelerated in opposite directions by electric fields and tend to separate. Strong electrostatic restoring forces are set up by this charge separation. Oscillations occur in the charge density. These oscillations are called *plasma oscillations* and are to be distinguished from lower-frequency oscillations which involve motion of the fluid, but no charge separation. The low-frequency oscillations are called *magnetohydrodynamic waves*.

In conducting liquids or dense ionized gases the collision frequency is sufficiently high even for very good conductors that there is a wide frequency range where Ohm's law in its simple form is valid. Under the action of applied fields the electrons and ions move in such a way that, apart from a high-frequency jitter, there is no separation of charge. Electric fields arise from motion of the fluid which causes a current flow, or as a result of time-varying magnetic fields or charge distributions external to the fluid. The mechanical motion of the system can then be described in terms of a single conducting fluid with the usual hydrodynamic variables of density, velocity, and pressure. At low frequencies it is customary to neglect the displacement current in Ampère's law. This is then the approximation that is called *magnetohydrodynamics*.

In less dense ionized gases the collision frequency is smaller. There may still be a low-frequency domain where the magnetohydrodynamic equations are applicable to quasi-stationary processes. Frequently astrophysical applications fall in this category. At higher frequencies, however, the neglect of charge separation and of the displacement current is not allowable. The separate inertial effects of the electrons and ions must be included in the description of the motion. This is the domain which we call *plasma physics*. There is here a range of physical conditions where a two-fluid model of electrons and ions gives an approximately correct description of various phenomena. But for high temperatures and low densities, the finite velocity spreads of the particles about their mean values must be included. Then the description is made in terms of the Boltzmann equation, with or without short-range correlations. We will not attempt to go into such details here. At still higher temperatures and lower densities, the electrostatic restoring forces become so weak that the length scale of charge separation becomes large compared to the size of the volume being considered. Then the collective behavior implicit in a fluid model is gone completely. We have left a few rapidly moving charged particles interacting via Coulomb collisions. A plasma is, by definition, an ionized gas in which the length that divides the 'small-scale individual-particle behavior from the large-scale collective behavior is small compared to the characteristic lengths of interest. This length, called the *Debye screening radius*, will be discussed in Section 10.9. It is numerically equal to $7.91 (T/n)^{1/2}$ cm, where T is the absolute temperature in degrees Kelvin and n is the number of electrons per cubic centimeter. For all but the hottest or most tenuous plasmas it is small compared to 1 cm.

10.2 Magnetohydrodynamic Equations

We first consider the behavior of an electrically neutral, conducting fluid in electromagnetic fields. For simplicity, we assume the fluid to be nonpermeable. It is described by a matter density $\rho(\mathbf{x}, t)$, a velocity $\mathbf{v}(\mathbf{x}, t)$, a pressure $p(\mathbf{x}, t)$ (taken to be a scalar), and a real conductivity σ . The hydrodynamic equations are the continuity equation

$$\rho \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v}) = 0 \quad (10.1)$$

and the force equation:

$$\rho \frac{d\mathbf{v}}{dt} = -\nabla p + \frac{1}{c} (\mathbf{J} \times \mathbf{B}) + \mathbf{F}_v + \rho \mathbf{g} \quad (10.2)$$

In addition to the pressure and magnetic-force terms we have included viscous and gravitational forces. For an incompressible fluid the viscous force can be written

$$\mathbf{F}_v = \eta \nabla^2 \mathbf{v} \quad (10.3)$$

where η is the coefficient of viscosity. It should be emphasized that the time derivative of the velocity on the left side of (10.2) is the *convective derivative*,

$$\frac{d}{dt} = \frac{\partial}{\partial t} + \mathbf{v} \cdot \nabla \quad (10.4)$$

which gives the total time rate of change of a quantity moving instantaneously with the velocity \mathbf{v} .

With the neglect of the displacement current, the electromagnetic fields in the fluid are described by

$$\left. \begin{aligned} \nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} &= 0 \\ \nabla \times \mathbf{B} &= \frac{4\pi}{c} \mathbf{J} \end{aligned} \right\} \quad (10.5)$$

The condition $\nabla \cdot \mathbf{J} = 0$, equivalent to the neglect of displacement currents, follows from the second equation in (10.5). The two divergence equations have been omitted in (10.5). It follows from Faraday's law that $(\partial/\partial t) \nabla \cdot \mathbf{B} = 0$, and the requirement $\nabla \cdot \mathbf{B} = 0$ can be imposed as an initial condition. With the neglect of the displacement current, it is appropriate to ignore Coulomb's law as well. The reason is that the electric field is completely determined by the curl equations and Ohm's law (see below). If the displacement current is retained in Ampère's law and $\nabla \cdot \mathbf{E} = 4\pi\rho_e$ is taken into account, corrections of only the order of (v^2/c^2) result. For normal magnetohydrodynamic problems these are completely negligible.

To complete the specification of dynamical equations we must specify the relation between the current density \mathbf{J} and the fields \mathbf{E} and \mathbf{B} . For a simple conducting medium of conductivity σ , Ohm's law applies, and the current density is

$$\mathbf{J}' = \sigma \mathbf{E}' \quad (10.6)$$

where \mathbf{J}' and \mathbf{E}' are measured in the rest frame of the medium. For a medium moving with velocity \mathbf{v} relative to the laboratory, we must transform both the current density and the electric field appropriately. The nonrelativistic transformation of the field is given by equation (6.10). The current density in the laboratory is similarly

$$\mathbf{J} = \mathbf{J}' + \rho_e \mathbf{v} \quad (10.7)$$

where ρ_e is the electrical charge density. For a one-component conducting fluid, $\rho_e = 0$. Consequently, Ohm's law assumes the form,

$$\mathbf{J} = \sigma \left(\mathbf{E} + \frac{\mathbf{v}}{c} \times \mathbf{B} \right) \quad (10.8)$$

Sometimes it is possible to assume that the conductivity of the fluid is effectively infinite. Then under the action of fields \mathbf{E} and \mathbf{B} the fluid flows in such a way that

$$\mathbf{E} + \frac{1}{c} (\mathbf{v} \times \mathbf{B}) = 0 \quad (10.9)$$

is satisfied.

Equations (10.1), (10.2), (10.5), and (10.8), supplemented by an equation of state for the fluid, form the equations of magnetohydrodynamics. In the next section we will consider some of the simpler aspects of them and will elaborate the basic concepts involved.

10.3 Magnetic Diffusion, Viscosity, and Pressure

The behavior of a fluid in the presence of electromagnetic fields is governed to a large extent by the magnitude of the conductivity. The effects are both electromagnetic and mechanical. We first consider the electromagnetic effects. We will see that, depending on the conductivity, quite different behaviors of the fields occur. The time dependence of the magnetic field can be written, using (10.8) to eliminate \mathbf{E} , in the form:

$$\frac{\partial \mathbf{B}}{\partial t} = \nabla \times (\mathbf{v} \times \mathbf{B}) + \frac{c^2}{4\pi\sigma} \nabla^2 \mathbf{B} \quad (10.10)$$

Here it is assumed that σ is constant in space. For a fluid at rest (10.10) reduces

to the diffusion equation

$$\frac{\partial \mathbf{B}}{\partial t} = \frac{c^2}{4\pi\sigma} \nabla^2 \mathbf{B} \quad (10.11)$$

This means that an initial configuration of magnetic field will decay away in a diffusion time

$$\tau = \frac{4\pi\sigma L^2}{c^2} \quad (10.12)$$

where L is a length characteristic of the spatial variation of \mathbf{B} . The time τ is of the order of 1 sec for a copper sphere of 1 cm radius, of the order of 10^4 years for the molten core of the earth, and of the order of 10^{10} years for a typical magnetic field in the sun.

For times short compared to the diffusion time τ (or, in other words, when the conductivity is so large that the second term in (10.10) can be neglected) the temporal behavior of the magnetic field is given by

$$\frac{\partial \mathbf{B}}{\partial t} = \nabla \times (\mathbf{v} \times \mathbf{B}) \quad (10.13)$$

From (6.5) and its accompanying footnote it can be seen that this is equivalent to the statement that the magnetic flux through any loop moving with the local fluid velocity is constant in time. We say that the lines of force are frozen into the fluid and are carried along with it. Since the conductivity is effectively infinite, (10.9) applies. The component of \mathbf{v} perpendicular to \mathbf{B} can be identified as the velocity \mathbf{w} of the lines of magnetic force:

$$\mathbf{w} = \frac{(\mathbf{B} \times \mathbf{v}) \times \mathbf{B}}{B^2} = c \frac{\mathbf{E} \times \mathbf{B}}{B^2} \quad (10.14)$$

This so-called “ $\mathbf{E} \times \mathbf{B}$ drift” of both fluid and lines of force can be understood in terms of individual particle orbits of the electrons and ions in crossed electric and magnetic fields (see Section 12.4).

A useful parameter to distinguish between situations in which diffusion of the field lines relative to the fluid occurs and those in which the lines of force are frozen in is the *magnetic Reynolds number* R_M . If V is a velocity typical of the problem and L is a corresponding length, then the magnetic Reynolds number is defined as

$$R_M = \frac{V\tau}{L} \quad (10.15)$$

where τ is the diffusion time (10.12). Transport of the lines of force with the fluid dominates over diffusion if $R_M \gg 1$. For liquids like mercury or sodium in the laboratory $R_M < 1$, except for very high velocities. But in geophysical and astrophysical applications R_M can be very large compared to unity.

The mechanical behavior of the system can be studied with the force equation (10.2). Substituting for \mathbf{J} from (10.8), we find

$$\rho \frac{d\mathbf{v}}{dt} = \mathbf{F} - \frac{\sigma B^2}{c^2} (\mathbf{v}_\perp - \mathbf{w}) \quad (10.16)$$

where \mathbf{F} is the sum of all the nonelectromagnetic forces, and \mathbf{v}_\perp is the component of velocity perpendicular to \mathbf{B} . From (10.16) it is apparent that flow parallel to \mathbf{B} is governed by the nonelectromagnetic forces alone. The velocity of flow of the fluid perpendicular to \mathbf{B} , on the other hand, decays from some initially arbitrary value in a time of the order of

$$\tau' = \frac{\rho c^2}{\sigma B^2} \quad (10.17)$$

to a value

$$\mathbf{v}_\perp = \mathbf{w} + \frac{c^2}{\sigma B^2} \mathbf{F}_\perp \quad (10.18)$$

In the limit of infinite conductivity this result reduces to that of (10.14), as expected. The term proportional to B^2 in (10.16) is an effective viscous or frictional force which tends to prevent flow of the fluid perpendicular to the lines of magnetic force. Sometimes it is described as a magnetic viscosity. If ordinary viscosity, here lumped into \mathbf{F} , is comparable to the magnetic viscosity, then the decay time τ' is shortened by an obvious factor involving the ratio of the two viscosities.

The above considerations have shown that if the conductivity is large the lines of force are frozen into the fluid and move along with it. Any departure from that state decays rapidly away. In considering the mechanical or electromagnetic effects we treated the opposite quantities as given, but the equations are, of course, coupled. In the limit of very large conductivity it is convenient to relate the current density \mathbf{J} in the force equation to the magnetic induction \mathbf{B} via Ampère's law and to use the infinite conductivity expression (10.9) to eliminate \mathbf{E} from Faraday's law to yield (10.13). The magnetic force term in (10.2) can now be written

$$\frac{1}{c} (\mathbf{J} \times \mathbf{B}) = -\frac{1}{4\pi} \mathbf{B} \times (\nabla \times \mathbf{B}) \quad (10.19)$$

With the vector identity

$$\frac{1}{2} \nabla (\mathbf{B} \cdot \mathbf{B}) = (\mathbf{B} \cdot \nabla) \mathbf{B} + \mathbf{B} \times (\nabla \times \mathbf{B}) \quad (10.20)$$

Equation (10.19) can be transformed into

$$\frac{1}{c} (\mathbf{J} \times \mathbf{B}) = -\nabla \left(\frac{B^2}{8\pi} \right) + \frac{1}{4\pi} (\mathbf{B} \cdot \nabla) \mathbf{B} \quad (10.21)$$

This equation shows that the magnetic force is equivalent to a *magnetic*

hydrostatic pressure,

$$p_M = \frac{B^2}{8\pi} \quad (10.22)$$

plus a term which can be thought of as an additional tension along the lines of force. The result (10.21) can also be derived from the Maxwell stress tensor (see Section 6.8).

If we neglect viscous effects and assume that the gravitational force is derivable from a potential $\mathbf{g} = -\nabla\psi$, the force equation (10.2) takes the form

$$\rho \frac{d\mathbf{v}}{dt} = -\nabla(p + p_M + \rho\psi) + \frac{1}{4\pi} (\mathbf{B} \cdot \nabla)\mathbf{B} \quad (10.23)$$

In some simple geometrical situations, such as \mathbf{B} having only one component, the additional tension vanishes. Then the static properties of the fluid are described by

$$p + p_M + \rho\psi = \text{constant} \quad (10.24)$$

This shows that, apart from gravitational effects, any change in mechanical pressure must be balanced by an opposite change in magnetic pressure. If the fluid is to be confined within a certain region so that p falls rapidly to zero outside that region, the magnetic pressure must rise equally rapidly in order to confine the fluid. This is the principle of the pinch effect discussed in Section 10.5.

10.4 Magnetohydrodynamic Flow between Boundaries with Crossed Electric and Magnetic Fields

To illustrate the competition between freezing in of lines of force and diffusion through them and between the $E \times B$ drift and behavior imposed by boundary conditions, we consider the simple example of an incompressible, but viscous, conducting fluid flowing in the x direction between two nonconducting boundary surfaces at $z=0$ and $z=a$, as shown in Fig. 10.1. The surfaces move with velocities V_1 and V_2 , respectively, in the x direction. A uniform magnetic field B_0 acts in the z direction. The system is infinite in the x and y directions. We will look for a steady-state solution for flow in the x direction in which the various quantities depend only upon z .

If the fields do not vary in time, it is clear from the Maxwell equations (10.5) that any electric field present must be an electrostatic field derivable from a potential and determined solely by the boundary conditions, i.e. an arbitrary external field. Expression (10.14) for the velocity of the lines of force when σ is infinite implies that there is an electric field in the y direction. If we assume that to be the only component of \mathbf{E} , then it must be a constant, E_0 . Because the

Fig. 10.1 Flow of viscous conducting fluid in a magnetic field between two plane surfaces moving with different velocities.

moving fluid will tend to carry the lines of force with it, we expect an x component $B_x(z)$ of magnetic induction, as well as the z component B_0 .

The continuity equation (10.1) reduces to $\nabla \cdot \mathbf{v} = 0$ for an incompressible fluid. This is satisfied identically by a velocity in the x direction which depends only on z . The force equation, neglecting gravity, has the steady-state form:

$$\nabla p = \frac{1}{c} (\mathbf{J} \times \mathbf{B}) + \eta \nabla^2 \mathbf{v} \quad (10.25)$$

The only component of \mathbf{J} that is nonvanishing is $J_y(z)$:

$$J_y(z) = \sigma \left[E_0 - \frac{1}{c} B_0 v(z) \right] \quad (10.26)$$

where v is the x component of velocity. When we write out the three component equations in (10.25), we find

$$\left. \begin{aligned} \frac{\partial p}{\partial x} &= \frac{\sigma B_0}{c} \left(E_0 - \frac{B_0}{c} v \right) + \eta \frac{\partial^2 v}{\partial z^2} \\ \frac{\partial p}{\partial y} &= 0 \\ \frac{\partial p}{\partial z} &= -\frac{\sigma B_x}{c} \left(E_0 - \frac{B_0}{c} v \right) \end{aligned} \right\} \quad (10.27)$$

The magnetic force in the z direction is just balanced by the pressure gradient. If we assume no pressure gradient in the x direction, the first of these equations can be written:

$$\frac{\partial^2 v}{\partial z^2} - \left(\frac{M}{a} \right)^2 v = - \left(\frac{M}{a} \right)^2 \frac{c E_0}{B_0} \quad (10.28)$$

where

$$M = \left(\frac{\sigma B_0^2 a^2}{\eta c^2} \right)^{1/2} \quad (10.29)$$

is called the *Hartmann number*. From (10.17) M^2 can be seen to be the ratio of magnetic to normal viscosity. The solution to (10.28), subject to the boundary conditions $v(0) = V_1$ and $v(a) = V_2$, is readily found to be

$$v(z) = \frac{V_1}{\sinh M} \sinh \left[M \left(\frac{a-z}{a} \right) \right] + \frac{V_2}{\sinh M} \sinh \left(\frac{Mz}{a} \right) + \frac{cE_0}{B_0} \left\{ 1 - \frac{\sinh \left[M \left(\frac{a-z}{a} \right) \right] + \sinh \left(\frac{Mz}{a} \right)}{\sinh M} \right\} \quad (10.30)$$

In the limit $B_0 \rightarrow 0$, $M \rightarrow 0$, we obtain the standard laminar-flow result

$$v(z) = V_1 + \frac{z}{a} (V_2 - V_1) \quad (10.31)$$

In the other limit of $M \gg 1$ we expect the magnetic viscosity to dominate and the flow to be determined almost entirely by the $E \times B$ drift. If we approximate $v(z)$ for $z \ll a$ and $M \gg 1$, we obtain

$$v(z) \approx \frac{cE_0}{B_0} + \left(V_1 - \frac{cE_0}{B_0} \right) e^{-Mz/a} \quad (10.32)$$

This shows that, while $v(z) = V_1$ exactly at the surface, there is a rapid transition in a distance of order (a/M) to the $E \times B$ drift value (cE_0/B_0) . Near $z = a$, (10.32) is changed by replacing V_1 by V_2 and z by $(a-z)$. The velocity profile in the two limits (10.31) and (10.32) is shown in Fig. 10.2.

The magnetic field $B_x(z)$ is determined by the equation

$$\frac{\partial B_x}{\partial z} = \frac{4\pi}{c} J_y = \frac{4\pi\sigma}{c} \left(E_0 - \frac{1}{c} B_0 v \right) \quad (10.33)$$

The boundary conditions on B_x at $z=0$ and $z=a$ are indeterminate unless we know the detailed history of how the steady state was created or can use some symmetry argument. All we know is that the difference in B_x is related to the total current flowing in the y direction per unit length in the x direction:

$$B_x(a) - B_x(0) = \frac{4\pi}{c} \int_0^a J_y(z) dz \quad (10.34)$$

This indeterminacy stems from the one-dimensional nature of the problem. For simplicity we will calculate the magnetic field only for the case when the total current in the y direction is zero.* Then we can assume that B_x vanishes at $z=0$

* This requirement means that $cE_0/B_0 = \frac{1}{2}(V_1 + V_2)$.

Fig. 10.2 Velocity profiles for large and small Hartmann numbers M . For $M \rightarrow 0$, laminar flow occurs. For $M \gg 1$, the flow is given by the $\mathbf{E} \times \mathbf{B}$ drift velocity, except in the immediate neighborhood of the boundaries.

and $z = a$. Using (10.30) for the velocity in (10.33), it is easy to show that then

$$B_x(z) = B_0 \left[\left(\frac{4\pi\sigma a^2}{c^2} \right) \left(\frac{V_2 - V_1}{2a} \right) \right] \left\{ \frac{\cosh \frac{M}{2} - \cosh \left(\frac{M}{2} - \frac{Mz}{a} \right)}{M \sinh \frac{M}{2}} \right\} \quad (10.35)$$

The dimensionless coefficient in square brackets in (10.35) may be identified as the magnetic Reynolds number (10.15), since $(V_2 - V_1)/2$ is a typical velocity in the problem and a is a typical length. In the two limits $M \ll 1$ and $M \gg 1$, (10.35) reduces to

$$B_x(z) \approx R_M B_0 \begin{cases} \frac{z}{a} \left(1 - \frac{z}{a} \right), & \text{for } M \ll 1 \\ \frac{1}{M} [1 - (e^{-Mz/a} + e^{-M[(a-z)/a]})], & \text{for } M \gg 1 \end{cases} \quad (10.36)$$

Figure 10.3 shows the behavior of the lines of force in the two limiting cases. Only for large R_M is there appreciable transport of the lines of force. And for a given R_M , the transport is less the larger the Hartmann number.

For liquid mercury at room temperature the relevant physical constants are

$$\sigma = 9.4 \times 10^{15} \text{ sec}^{-1}$$

$$\eta = 1.5 \times 10^{-2} \text{ poise}$$

$$\rho = 13.5 \text{ gm/cm}^3$$

The diffusion time (10.12) is $\tau = 1.31 \times 10^{-4} [L \text{ (cm)}]^2 \text{ sec}$. The Hartmann number

Fig. 10.3 (a) Axial component of magnetic induction between the boundary surfaces for large and small Hartmann numbers. (b) Transport of lines of magnetic induction in direction of flow.

(10.29) is $M = 2.64 \times 10^{-2} B_0(\text{gauss}) a(\text{cm})$. With $L \approx a \approx 1$ cm, this gives a magnetic Reynolds number $R_M \sim 10^{-4} V$. Consequently unless the flow velocity is very large, there is no significant transport of lines of force for laboratory experiments with mercury. On the other hand, if the magnetic induction B_0 is of the order of 10^4 gauss, then $M \sim 250$ and the velocity flow is almost completely specified by the $E \times B$ drift (10.14). In geomagnetic problems with the earth's core and in astrophysical problems the parameters (e.g., the length scale) are such that $R_M \gg 1$ occurs often and transport of the lines of force becomes very important.

10.5 Pinch Effect

The confinement of a plasma or conducting fluid by self-magnetic fields is of considerable interest in thermonuclear research, as well as in other applications. To illustrate the principles we consider an infinite cylinder of conducting fluid with an axial current density $J_z = J(r)$ and a resulting azimuthal magnetic induction $B_\phi = B(r)$. For simplicity, the current density, magnetic field, pressure, etc., are assumed to depend only on the distance r from the cylinder axis, and viscous and gravitational effects are neglected. We first ask whether a steady-state condition can exist in which the material is mainly confined within a certain radius $r = R$ by the action of its own magnetic induction. For a steady state with $d\mathbf{v}/dt = 0$ the equation of motion (10.23) of the fluid reduces to

$$0 = -\frac{dp}{dr} - \frac{d}{dr} \left(\frac{B^2}{8\pi} \right) - \frac{B^2}{4\pi r} \quad (10.37)$$

Ampère's law in integral form relates $B(r)$ to the current enclosed:

$$B(r) = \frac{4\pi}{cr} \int_0^r rJ(r) dr \quad (10.38)$$

A number of results can be obtained without specifying the form of $J(r)$, aside from physical limitations of finiteness, etc. From Ampère's law it is evident that, if the fluid lies almost entirely inside $r = R$, then the magnetic induction outside the fluid is

$$B(r) = \frac{2I}{cr} \quad (10.39)$$

where

$$I = \int_0^R 2\pi r J(r) dr$$

is the total current flowing in the cylinder. Equation (10.37) can be written as

$$\frac{dp}{dr} = -\frac{1}{8\pi r^2} \frac{d}{dr} (r^2 B^2) \quad (10.40)$$

with the solution:

$$p(r) = p_0 - \frac{1}{8\pi} \int_0^r \frac{1}{r^2} \frac{d}{dr} (r^2 B^2) dr \quad (10.41)$$

Here p_0 is the pressure of the fluid at $r=0$. If the matter is confined to $r \leq R$, the pressure drops to zero at $r=R$. Consequently the axial pressure p_0 is given by

$$p_0 = \frac{1}{8\pi} \int_0^R \frac{1}{r^2} \frac{d}{dr} (r^2 B^2) dr \quad (10.42)$$

The upper limit of integration can be replaced by infinity, since the integrand vanishes for $r \geq R$, as can be seen from (10.39). With this expression (10.42) for p_0 , (10.41) can be written as

$$p(r) = \frac{1}{8\pi} \int_r^R \frac{1}{r^2} \frac{d}{dr} (r^2 B^2) dr \quad (10.43)$$

The average pressure inside the cylinder can be related to the total current I and radius R without specifying the detailed radial behavior. Thus

$$\langle p \rangle = \frac{2\pi}{\pi R^2} \int_0^R r p(r) dr \quad (10.44)$$

Integration by parts and use of (10.40) gives

$$\langle p \rangle = \frac{I^2}{2\pi R^2 c^2} \quad (10.45)$$

as the relation between average pressure, total current, and radius of the cylinder of fluid or plasma confined by its own magnetic field. Note that the average pressure of the matter is equal to the magnetic pressure ($B^2/8\pi$) at the surface of the cylinder. In thermonuclear work, hot plasmas with temperatures of the order of 10^8 °K ($kT \sim 10$ keV) and densities of the order of 10^{15}

Fig. 10.4. Variation of azimuthal magnetic induction and pressure with radius in a cylindrical plasma column with a uniform current density J .

particles/cm³ are envisioned. These conditions correspond to a pressure of approximately $10^{15} \times 10^8 k \approx 1.4 \times 10^7$ dynes/cm², or 14 atmospheres. A magnetic induction of approximately 19 kilogauss at the surface, corresponding to a current of $9 \times 10^4 R$ (cm) amperes, is necessary for confinement. This shows that extremely high currents are needed to confine very hot plasmas.

So far the radial behavior of the system has not been discussed. Two simple examples will serve to illustrate the possibilities. One is that the current density $J(r)$ is constant for $r < R$. Then $B(r) = (2Ir/cR^2)$ for $r < R$. Equation (10.43) then yields a parabolic dependence for pressure versus radius:

$$p(r) = \frac{I^2}{\pi c^2 R^2} \left(1 - \frac{r^2}{R^2} \right) \quad (10.46)$$

The axial pressure p_0 is then twice the average pressure $\langle p \rangle$. The radial dependences of the various quantities are sketched in Fig. 10.4.

The other model has the current density confined to a very thin layer on the surface, as is appropriate for a highly conducting fluid or plasma. The magnetic

Fig. 10.5 Variation of azimuthal magnetic induction and pressure in a cylindrical plasma column with a surface current density.

induction is given by (10.39) for $r > R$, but vanishes inside the cylinder. Then the pressure p is constant inside the cylinder and equal to the value (10.45). This is sketched in Fig. 10.5.

10.6 Instabilities in a Pinched Plasma Column

The steady-state situation of the previous section is an ideal that cannot be achieved in the laboratory without topologies of fields and currents considerably more complicated than the simple cylindrical geometry discussed there. The reason is that a self-pinched plasma is subject to numerous instabilities. There are magnetohydrodynamic instabilities that can be understood in terms of magnetic pressures and stresses and there are instabilities associated with particle motion. We consider only the first kind here and restrict the discussion to qualitative aspects of two of the simpler varieties of instability. We take as the starting point a uniform cylindrical column of plasma with a surrounding magnetic field and ask what happens when there are departures in shape from the cylindrical cylinder of constant radius.

The first instability is the *kink instability*, shown in Fig. 10.6a. The lines of azimuthal magnetic induction near the column are bunched together above, and separated below, the column by the distortion downwards. Thus the magnetic pressure changes are in such a direction as to increase the distortion. The distortion is unstable.

The second type of distortion is called a *sausage or neck instability*, shown in Fig. 10.6b. In the neighborhood of the constriction the azimuthal induction

Fig. 10.6 (a) Kink instability. (b) Sausage or neck instability.

Fig. 10.7 Hindering neck instability with outward pressure of trapped axial magnetic fields.

increases, causing a greater inwards pressure at the neck than elsewhere. This serves to enhance the existing distortion.

Both types of instability are hindered by axial magnetic fields within the plasma column. For the sausage distortion the lines of axial induction are compressed by the constriction, causing an increased pressure inside to oppose the increased pressure of the azimuthal field, as indicated schematically in Fig. 10.7. It is easy to show that the fractional changes in the two magnetic pressures, assuming a sharp boundary to the plasma, are

$$\frac{\Delta p_\phi}{p_\phi} = \frac{2x}{R}, \quad \frac{\Delta p_z}{p_z} = \frac{4x}{R} \quad (10.47)$$

where x is the small inwards displacement. Consequently, if

$$B_z^2 > \frac{1}{2} B_\phi^2 \quad (10.48)$$

the column is stable against sausage distortions.

For kinks the axial magnetic field lines are stretched, rather than compressed laterally together. But the result is the same; namely the increased tension in the field lines inside opposes the external forces and tends to stabilize the column. It is evident from Fig. 10.8 that a short-wavelength kink of a given lateral displacement will cause the lines of force to stretch relatively more than a long-wavelength kink. Consequently, for a given ratio of internal axial field to external azimuthal field, there will be a tendency to stabilize short-wavelength kinks, but not very long-wavelength ones. If the fields are approximately equal,

Fig. 10.8 Hindering kink instability with tension of trapped axial fields.

Fig. 10.9 Stabilization of long-wavelength kinks with outer conductor.

analysis shows that if the wavelength of the kink $\lambda < 14 R$ the disturbance is stabilized.

For longer-wavelength kinks stabilization can be achieved by the action of an outer conductor, provided the plasma radius is not too small compared to the radius of the conductor. The azimuthal field lines are trapped between the conductor and the plasma boundary, as shown in Fig. 10.9. If the plasma column moves too close to the walls, the lines of force are crowded together between it and the walls, causing an increased magnetic pressure and restoring force.

It is clear qualitatively that it must be possible, by a combination of trapped axial field and conducting walls, to create a stable configuration, at least in the approximation of a highly conducting plasma with a sharp boundary. Detailed analysis* confirms this qualitative conclusion and sets limits on the quantities involved. It is important to have as little axial field outside the plasma as possible and to keep the plasma radius of the order of one-half or one-third of the cylinder radius. If the axial field outside the plasma is too large, the combined B_z and B_ϕ cause helical instabilities that are troublesome in toroidal geometries. If, however, the axial field outside the plasma is made very large, the pitch of the helix becomes so great that there is much less than one turn of the helix in a plasma column of finite length. Then it turns out that there is the possibility of stability again. Stabilization by means of a strong axial field produced by currents external to the plasma is the basis of some fusion devices, for example the Stellarator.

The idealized situation of a sharp plasma boundary is difficult to create experimentally, and even when created is destroyed by diffusion of the plasma through the lines of force in times of the order of $4\pi\sigma R^2/c^2$ (see Section 10.3). For a hydrogen plasma of 1 eV energy per particle this time is of the order of 10^{-4} sec for $R \sim 10$ cm, while for a 10 keV plasma it is of the order of 10^2 sec. Clearly the thermonuclear experimenter must try to create initially as hot a plasma as possible in order to make the initial diffusion time long enough to allow further heating.

10.7 Magnetohydrodynamic Waves

In ordinary hydrodynamics, apart from surface waves the only small-amplitude waves possible are longitudinal, compressional (sound) waves. These propagate with a velocity s related to the derivative of pressure with respect to density at constant entropy:

$$s^2 = \left(\frac{\partial p}{\partial \rho} \right)_0 \quad (10.49)$$

If the adiabatic law $p = K\rho^\gamma$ is assumed, $s^2 = \gamma p_0/\rho_0$, where γ is the ratio of specific heats. In magnetohydrodynamics another type of wave motion is possible. It is associated with the transverse motion of lines of magnetic induction. The tension in the lines of force tends to restore them to straight-line form, thereby causing a transverse oscillation. By analogy with ordinary sound waves whose velocity squared is of the order of the hydrostatic pressure divided by the density, we expect that these magnetohydrodynamic waves, called *Alfvén waves*, will have a velocity

$$v \sim \left(\frac{B_0^2}{8\pi\rho_0} \right)^{1/2} \quad (10.50)$$

where $B_0^2/8\pi$ is the magnetic pressure.

To examine the wave motion of a conducting fluid in the presence of a magnetic field, we consider a compressible, nonviscous, perfectly conducting fluid in a magnetic field in the absence of gravitational forces. The appropriate equations governing its behavior are:

$$\left. \begin{aligned} \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v}) &= 0 \\ \rho \frac{\partial \mathbf{v}}{\partial t} + \rho(\mathbf{v} \cdot \nabla) \mathbf{v} &= -\nabla p - \frac{1}{4\pi} \mathbf{B} \times (\nabla \times \mathbf{B}) \\ \frac{\partial \mathbf{B}}{\partial t} &= \nabla \times (\mathbf{v} \times \mathbf{B}) \end{aligned} \right\} \quad (10.51)$$

These must be supplemented by an equation of state relating the pressure to the density. We assume that the equilibrium velocity is zero, but that there exists a spatially uniform, static, magnetic induction \mathbf{B}_0 throughout the uniform fluid of constant density ρ_0 . Then we imagine small-amplitude departures from the equilibrium values:

$$\left. \begin{aligned} \mathbf{B} &= \mathbf{B}_0 + \mathbf{B}_1(\mathbf{x}, t) \\ \rho &= \rho_0 + \rho_1(\mathbf{x}, t) \\ \mathbf{v} &= \mathbf{v}_1(\mathbf{x}, t) \end{aligned} \right\} \quad (10.52)$$

If equations (10.51) are linearized in the small quantities, they then become:

$$\left. \begin{aligned} \frac{\partial \rho_1}{\partial t} + \rho_0 \nabla \cdot \mathbf{v}_1 &= 0 \\ \rho_0 \frac{\partial \mathbf{v}_1}{\partial t} + s^2 \nabla \rho_1 + \frac{\mathbf{B}_0}{4\pi} \times (\nabla \times \mathbf{B}_1) &= 0 \\ \frac{\partial \mathbf{B}_1}{\partial t} - \nabla \times (\mathbf{v}_1 \times \mathbf{B}_0) &= 0 \end{aligned} \right\} \quad (10.53)$$

where s^2 is the square of the sound velocity (10.49). These equations can be combined to yield an equation for \mathbf{v}_1 alone:

$$\frac{\partial^2 \mathbf{v}_1}{\partial t^2} - s^2 \nabla (\nabla \cdot \mathbf{v}_1) + \mathbf{v}_A \times \nabla \times [\nabla \times (\mathbf{v}_1 \times \mathbf{v}_A)] = 0 \quad (10.54)$$

where we have introduced a vectorial *Alfvén velocity*:

$$\mathbf{v}_A = \frac{\mathbf{B}_0}{\sqrt{4\pi\rho_0}} \quad (10.55)$$

The wave equation (10.54) for \mathbf{v}_1 is somewhat involved, but it allows simple solutions for waves propagating parallel or perpendicular to the magnetic field direction.* With $\mathbf{v}_1(\mathbf{x}, t)$ a plane wave with wave vector \mathbf{k} and frequency ω :

$$\mathbf{v}_1(\mathbf{x}, t) = \mathbf{v}_1 e^{i\mathbf{k} \cdot \mathbf{x} - i\omega t} \quad (10.56)$$

equation (10.54) becomes:

$$-\omega^2 \mathbf{v}_1 + (s^2 + v_A^2)(\mathbf{k} \cdot \mathbf{v}_1)\mathbf{k} + \mathbf{v}_A \cdot \mathbf{k} [(\mathbf{v}_A \cdot \mathbf{k})\mathbf{v}_1 - (\mathbf{v}_A \cdot \mathbf{v}_1)\mathbf{k} - (\mathbf{k} \cdot \mathbf{v}_1)\mathbf{v}_A] = 0 \quad (10.57)$$

If \mathbf{k} is perpendicular to \mathbf{v}_A the last term vanishes. Then the solution for \mathbf{v}_1 is a longitudinal magnetosonic wave with a phase velocity:

$$u_{\text{long}} = \sqrt{s^2 + v_A^2} \quad (10.58)$$

Note that this wave propagates with a velocity which depends on the sum of hydrostatic and magnetic pressures, apart from factors of the order of unity. If \mathbf{k} is parallel to \mathbf{v}_A , (10.57) reduces to

$$(k^2 v_A^2 - \omega^2) \mathbf{v}_1 + \left(\frac{s^2}{v_A^2} - 1 \right) k^2 (\mathbf{v}_A \cdot \mathbf{v}_1) \mathbf{v}_A = 0 \quad (10.59)$$

There are two types of wave motion possible in this case. There is an ordinary longitudinal wave (\mathbf{v}_1 parallel to \mathbf{k} and \mathbf{v}_A) with phase velocity equal to the sound velocity s . But there is also a *transverse* wave ($\mathbf{v}_1 \cdot \mathbf{v}_A = 0$) with a phase velocity

* The determination of the characteristics of the waves for arbitrary direction of propagation is left to Problem 10.3.

equal to the Alfvén velocity v_A . This Alfvén wave is a purely magnetohydrodynamic phenomenon which depends only on the magnetic field (tension) and the density (inertia).

For mercury at room temperature the Alfvén velocity is $[B_0 \text{ (gauss)}/13.1] \text{ cm/sec}$, compared with sound speed of $1.45 \times 10^5 \text{ cm/sec}$. At all laboratory field strengths the Alfvén velocity is much less than the speed of sound. In astrophysical problems, on the other hand, the Alfvén velocity can become very large because of the much smaller densities. In the sun's photosphere, for example, the density is of the order of 10^{-7} gm/cm^3 ($\sim 6 \times 10^{16}$ hydrogen atoms/cm³) so that $v_A \approx 10^3 B_0 \text{ cm/sec}$. Solar magnetic fields appear to be of the order of 1 or 2 gauss at the surface, with much larger values around sunspots. For comparison, the velocity of sound is of the order of 10^6 cm/sec in both the photosphere and the chromosphere.

The magnetic fields of these different waves can be found from the third equation in (10.53):

$$\mathbf{B}_1 = \begin{cases} \frac{k}{\omega} v_1 \mathbf{B}_0 & \text{for } \mathbf{k} \perp \mathbf{B}_0 \\ 0 & \text{for the longitudinal } \mathbf{k} \parallel \mathbf{B}_0 \\ -\frac{k}{\omega} B_0 \mathbf{v}_1 & \text{for the transverse } \mathbf{k} \parallel \mathbf{B}_0 \end{cases} \quad (10.60)$$

The magnetosonic wave moving perpendicular to \mathbf{B}_0 causes compressions and rarefactions in the lines of force without changing their direction, as indicated in Fig. 10.10a. The Alfvén wave parallel to \mathbf{B}_0 causes the lines of force to oscillate back and forth laterally (Fig. 10.10b). In either case the lines of force are "frozen in" and move with the fluid.

If the conductivity of the fluid is not infinite or viscous effects are present, we anticipate dissipative losses and a consequent damping of oscillations. The second and third equations in (10.53) are modified by additional terms:

$$\left. \begin{aligned} \rho_0 \frac{\partial \mathbf{v}_1}{\partial t} &= -s^2 \nabla \rho_1 - \frac{\mathbf{B}_0}{4\pi} \times (\nabla \times \mathbf{B}_1) + \eta \nabla^2 \mathbf{v}_1 \\ \frac{\partial \mathbf{B}_1}{\partial t} &= \nabla \times (\mathbf{v}_1 \times \mathbf{B}_0) + \frac{c^2}{4\pi\sigma} \nabla^2 \mathbf{B}_1 \end{aligned} \right\} \quad (10.61)$$

where η is the viscosity* and σ is the conductivity. Since both additions cause dispersion in the phase velocity, their effects are most easily seen when a plane wave solution is being sought. For plane waves it is evident that these equations

* Use of the simple viscous force (10.3) is not really allowed for a compressible fluid. But it can be expected to give the correct qualitative behavior.

Fig. 10.10 Magnetohydrodynamic waves.

are equivalent to

$$\left. \begin{aligned} \rho_0 \frac{\partial \mathbf{v}_1}{\partial t} &= \frac{1}{\left(1 + i \frac{\eta k^2}{\rho_0 \omega}\right)} \left[-s^2 \nabla \rho_1 - \frac{\mathbf{B}_0}{4\pi} \times (\nabla \times \mathbf{B}_1) \right] \\ \frac{\partial \mathbf{B}_1}{\partial t} &= \frac{1}{\left(1 + i \frac{c^2 k^2}{4\pi \sigma \omega}\right)} \nabla \times (\mathbf{v}_1 \times \mathbf{B}_0) \end{aligned} \right\} \quad (10.62)$$

Consequently equation (10.57) relating k and ω is modified by (a) multiplying s^2 and ω^2 by the factor $\left(1 + i \frac{c^2 k^2}{4\pi \sigma \omega}\right)$, and (b) multiplying ω^2 by the factor $\left(1 + i \frac{\eta k^2}{\rho_0 \omega}\right)$.

For the important case of the Alfvén wave parallel to the field, the relation between ω and k becomes

$$k^2 v_A^2 = \omega^2 \left(1 + i \frac{c^2 k^2}{4\pi \sigma \omega}\right) \left(1 + i \frac{\eta k^2}{\rho_0 \omega}\right) \quad (10.63)$$

If the resistive and viscous correction terms are small, the wave number is approximately

$$k \approx \frac{\omega}{v_A} + i \frac{\omega^2}{2v_A^3} \left(\frac{c^2}{4\pi \sigma} + \frac{\eta}{\rho_0} \right) \quad (10.64)$$

This shows that the attenuation increases rapidly with frequency (or wave number), but decreases with increasing magnetic field strength. In terms of the diffusion time τ of Section 10.3, the imaginary part of the wave number shows that, apart from viscosity effects, the wave travels for a time τ before falling to $1/e$ of its original intensity, where the length parameter in τ (10.12) is the wavelength of oscillation. For the opposite extreme in which the resistive and/or viscous terms dominate, the wave number is given by the vanishing of the two

factors on the right-hand side of (10.63). Thus k has equal real and imaginary parts and the wave is damped out rapidly, independent of the magnitude of the magnetic field.

The considerations of magnetohydrodynamic waves given above are valid only at comparatively low frequencies, since the displacement current was ignored in Ampère's law. It is evident that, if the frequency is high enough, the behavior of the fields must go over into the "ionospheric" behavior described in Section 7.6, where charge-separation effects play an important role. But even when charge-separation effects are neglected in the magnetohydrodynamic description, the displacement current modifies the propagation of the Alfvén and magnetosonic waves. The form of Ampère's law, including the displacement current, is:

$$\nabla \times \mathbf{B} = \frac{4\pi}{c} \mathbf{J} - \frac{1}{c^2} \frac{\partial}{\partial t} (\mathbf{v} \times \mathbf{B}) \quad (10.65)$$

where we have used the infinite conductivity approximation (10.9) in eliminating the electric field \mathbf{E} . Thus the current to be inserted into the force equation for fluid motion is now

$$\mathbf{J} = \frac{c}{4\pi} \left[\nabla \times \mathbf{B} + \frac{1}{c^2} \frac{\partial}{\partial t} (\mathbf{v} \times \mathbf{B}) \right] \quad (10.66)$$

In the linearized set of equations (10.53) the second one is then generalized to read:

$$\rho_0 \left[\frac{\partial \mathbf{v}_1}{\partial t} + \frac{1}{c^2} \mathbf{v}_A \times \left(\frac{\partial \mathbf{v}_1}{\partial t} \times \mathbf{v}_A \right) \right] = -s^2 \nabla \rho_1 - \frac{\mathbf{B}_0}{4\pi} \times (\nabla \times \mathbf{B}_1) \quad (10.67)$$

This means that the wave equation for \mathbf{v}_1 is altered to the form:

$$\frac{\partial^2}{\partial t^2} \left[\mathbf{v}_1 \left(1 + \frac{v_A^2}{c^2} \right) - \frac{\mathbf{v}_A}{c^2} (\mathbf{v}_A \cdot \mathbf{v}_1) \right] - s^2 \nabla (\nabla \cdot \mathbf{v}_1) + \mathbf{v}_A \times \nabla \times \nabla \times (\mathbf{v}_1 \times \mathbf{v}_A) = 0 \quad (10.68)$$

Inspection shows that for \mathbf{v}_1 parallel to \mathbf{v}_A (i.e., \mathbf{B}_0) there is no change from before. But for transverse \mathbf{v}_1 (either magnetosonic with \mathbf{k} perpendicular to \mathbf{B}_0 or Alfvén waves with \mathbf{k} parallel to \mathbf{B}_0) the square of the frequency is multiplied by a factor $[1 + (v_A^2/c^2)]$. Thus the phase velocity of Alfvén waves becomes

$$u_A = \frac{c v_A}{\sqrt{c^2 + v_A^2}} \quad (10.69)$$

In the usual limit where $v_A \ll c$, the velocity is approximately equal to v_A ; the displacement current is unimportant. But, if $v_A \gg c$, then the phase velocity is equal to the velocity of light. From the point of view of electromagnetic waves, the transverse Alfvén wave can be thought of as a wave in a medium with an index of refraction given by

$$u_A = \frac{c}{n} \quad (10.70)$$

Thus

$$n^2 = 1 + \frac{c^2}{v_A^2} = 1 + \frac{4\pi\rho_0 c^2}{B_0^2} \quad (10.71)$$

Caution must be urged in using this index of refraction for the propagation of electromagnetic waves in a plasma. It is valid only at frequencies where charge-separation effects are unimportant.

10.8 Plasma Oscillations

The magnetohydrodynamic approximation considered in the previous sections is based on the concept of a single-component, electrically neutral fluid with a scalar conductivity σ to describe its interaction with the electromagnetic field. As discussed in the introduction to this chapter a conducting fluid or plasma is, however, a multicomponent fluid with electrons and one or more types of ions present. At low frequencies or long wavelengths the description in terms of a single fluid is valid because the collision frequency ν is large enough (and the mean free path short enough) that the electrons and ions always maintain local electrical neutrality, while on the average drifting in opposite directions according to Ohm's law under the action of electric fields. At higher frequencies the single-fluid model breaks down. The electrons and ions tend to move independently, and charge separations occur. These charge separations produce strong restoring forces. Consequently oscillations of an electrostatic nature are set up. If a magnetic field is present, other effects occur. The electrons and ions tend to move in circular or helical orbits in the magnetic field with orbital frequencies given by

$$\omega_B = \frac{eB}{mc} \quad (10.72)$$

When the fields are strong enough or the densities low enough that the orbital frequencies are comparable to the collision frequency, the concept of a scalar conductivity breaks down and the current flow exhibits a marked directional dependence relative to the magnetic field (see Problem 10.5). At still higher frequencies the greater inertia of the ions implies that they will be unable to follow the rapid fluctuation of the fields. Only the electrons partake in the motion. The ions merely provide a uniform background of positive charge to give electrical neutrality on the average. The idea of a uniform background of charge, and indeed the concept of an electron fluid, is valid only when we are considering a scale of length which is at least large compared to interparticle spacings ($l \gg n_0^{-1/3}$). In fact, there is another limit, the Debye screening length, which for plasmas at reasonable temperatures is greater than $n_0^{-1/3}$, and which forms the actual dividing line between small-scale individual-particle motion and collective fluid motion (see the following section).

To avoid undue complications we consider only the high-frequency behavior of a plasma, ignoring the dynamical effects of the ions. We also ignore the effects of collisions. The electrons of charge e and mass m are described by a density $n(\mathbf{x}, t)$ and an average velocity $\mathbf{v}(\mathbf{x}, t)$. The equilibrium charge density of ions and electrons is $\mp en_0$. The dynamical equations for the electron fluid are

$$\left. \begin{aligned} \frac{\partial n}{\partial t} + \nabla \cdot (n\mathbf{v}) &= 0 \\ \frac{\partial \mathbf{v}}{\partial t} + (\mathbf{v} \cdot \nabla)\mathbf{v} &= \frac{e}{m} \left(\mathbf{E} + \frac{\mathbf{v}}{c} \times \mathbf{B} \right) - \frac{1}{mn} \nabla p \end{aligned} \right\} \quad (10.73)$$

where the effects of the thermal kinetic energy of the electrons are described by the electron pressure p (here assumed a scalar). The charge and current densities are:

$$\left. \begin{aligned} \rho_e &= e(n - n_0) \\ \mathbf{J} &= en\mathbf{v} \end{aligned} \right\} \quad (10.74)$$

Thus the Maxwell equations can be written

$$\left. \begin{aligned} \nabla \cdot \mathbf{E} &= 4\pi e(n - n_0) \\ \nabla \cdot \mathbf{B} &= 0 \\ \nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} &= 0 \\ \nabla \times \mathbf{B} - \frac{1}{c} \frac{\partial \mathbf{E}}{\partial t} &= \frac{4\pi en}{c} \mathbf{v} \end{aligned} \right\} \quad (10.75)$$

We now assume that the static situation is the electron fluid at rest with $n = n_0$ and no fields present, and consider the small departures from that state due to some initial disturbance. The linearized equations of motion are

$$\left. \begin{aligned} \frac{\partial n}{\partial t} + n_0 \nabla \cdot \mathbf{v} &= 0 \\ \frac{\partial \mathbf{v}}{\partial t} - \frac{e}{m} \mathbf{E} + \frac{1}{mn_0} \left(\frac{\partial p}{\partial n} \right)_0 \nabla n &= 0 \\ \nabla \cdot \mathbf{E} - 4\pi en &= 0 \\ \nabla \times \mathbf{B} - \frac{1}{c} \frac{\partial \mathbf{E}}{\partial t} - \frac{4\pi en_0}{c} \mathbf{v} &= 0 \end{aligned} \right\} \quad (10.76)$$

plus the two homogeneous Maxwell equations. Here $n(\mathbf{x}, t)$ and $\mathbf{v}(\mathbf{x}, t)$ represent departures from equilibrium. If an external magnetic field \mathbf{B}_0 is present a $[(\mathbf{v}/c) \times \mathbf{B}_0]$ term must be kept in the force equation (see Problem 10.7), but the fluctuation field \mathbf{B} is of first order in small quantities so that $(\mathbf{v} \times \mathbf{B})$ is second

order. The continuity equation is actually not an independent equation, but may be derived by combining the last two equations in (10.76).

Since the force equation in (10.76) is independent of magnetic field, we suspect that there exist solutions of a purely electrostatic nature, with $\mathbf{B}=0$. The continuity and force equations can be combined to yield a wave equation for the density fluctuations:

$$\frac{\partial^2 n}{\partial t^2} + \left(\frac{4\pi e^2 n_0}{m} \right) n - \frac{1}{m} \left(\frac{\partial p}{\partial n} \right)_0 \nabla^2 n = 0 \quad (10.77)$$

On the other hand, the time derivative of Ampère's law and the force equation can be combined to give an equation for the fields:

$$\frac{\partial^2 \mathbf{E}}{\partial t^2} + \left(\frac{4\pi e^2 n_0}{m} \right) \mathbf{E} - \frac{1}{m} \left(\frac{\partial p}{\partial n} \right)_0 \nabla (\nabla \cdot \mathbf{E}) = c \nabla \times \frac{\partial \mathbf{B}}{\partial t} \quad (10.78)$$

The structures of the left-hand sides of these two equations are essentially identical. Consequently no inconsistency arises if we put $\partial \mathbf{B} / \partial t = 0$. Having excluded static fields already, we conclude that $\mathbf{B}=0$ is a possibility. If $\partial \mathbf{B} / \partial t = 0$, then Faraday's law implies $\nabla \times \mathbf{E} = 0$. Hence \mathbf{E} is a longitudinal field derivable from a scalar potential. It is immediately evident that each component of \mathbf{E} satisfies the same equation (10.77) as the density fluctuations. If the pressure term in (10.77) is neglected, we find that the density, velocity, and electric field all oscillate with the plasma frequency ω_p :

$$\omega_p^2 = \frac{4\pi n_0 e^2}{m} \quad (10.79)$$

If the pressure term is included, we obtain a dispersion relation for the frequency:

$$\omega^2 = \omega_p^2 + \frac{1}{m} \left(\frac{\partial p}{\partial n} \right)_0 k^2 \quad (10.80)$$

The determination of the coefficient of k^2 takes some care. The adiabatic law $p = p_0(n/n_0)^\gamma$ can be assumed, but the customary acoustical value $\gamma = \frac{5}{3}$ for a gas of particles with 3 external, but no internal, degrees of freedom is not valid. The reason is that the frequency of the present density oscillations is much higher than the collision frequency, contrary to the acoustical limit. Consequently the one-dimensional nature of the density oscillations is maintained. A value of γ appropriate to 1 translational degree of freedom must be used. Since $\gamma = (m+2)/m$, where m is the number of degrees of freedom, we have in this case $\gamma = 3$. Then

$$\frac{1}{m} \left(\frac{\partial p}{\partial n} \right)_0 = 3 \frac{p_0}{m n_0} \quad (10.81)$$

If we use $p_0 = n_0 K T$ and define the rms velocity component in one direction (parallel to the electric field),

$$m \langle u^2 \rangle = K T = \frac{p_0}{n_0} \quad (10.82)$$

then the dispersion equation can be written

$$\omega^2 = \omega_p^2 + 3 \langle u^2 \rangle k^2 \quad (10.83)$$

This relation is an approximate one, valid for long wavelengths, and is actually just the first two terms in an expansion involving higher and higher moments of the velocity distribution of the electrons (see Problem 10.6). In form (10.83) the dispersion equation has a validity beyond the ideal gas law which was used in the derivation. For example, it applies to plasma oscillations in a degenerate Fermi gas of electrons in which all cells in velocity space are filled inside a sphere of radius equal to the Fermi velocity V_F . Then the average value of the square of a component of velocity is

$$\langle u^2 \rangle = \frac{1}{3} V_F^2 \quad (10.84)$$

Quantum effects appear explicitly in the dispersion equation only in higher-order terms in the expansion in powers of k^2 .

The oscillations described above are longitudinal electrostatic oscillations in which the oscillating magnetic field vanishes identically. This means that they cannot give rise to radiation in an unbounded plasma. There are, however, modes of oscillation in a plasma which are transverse electromagnetic waves. To see the various possibilities of plasma oscillations we assume that all variables vary as $\exp(i\mathbf{k} \cdot \mathbf{x} - i\omega t)$ and look for a defining relationship between ω and \mathbf{k} , as we did for the magnetohydrodynamic waves in Section 10.7. With this assumption the linearized equations (10.76) and the two homogeneous Maxwell equations can be written:

$$\left. \begin{aligned} n &= \frac{\mathbf{k} \cdot \mathbf{v}}{\omega} n_0 \\ \mathbf{v} &= \frac{ie\mathbf{E}}{m\omega} + \frac{3\langle u^2 \rangle}{\omega} \frac{n}{n_0} \mathbf{k} \\ \mathbf{k} \cdot \mathbf{E} &= -i4\pi en \\ \mathbf{k} \cdot \mathbf{B} &= 0 \\ \mathbf{k} \times \mathbf{B} &= -\frac{\omega}{c} \mathbf{E} - i \frac{4\pi en_0}{c} \mathbf{v} \\ \mathbf{k} \times \mathbf{E} &= \frac{\omega}{c} \mathbf{B} \end{aligned} \right\} \quad (10.85)$$

The Maxwell equations can be solved for \mathbf{v} in terms of \mathbf{k} and \mathbf{E} :

$$\mathbf{v} = \left(\frac{ie}{m\omega} \right) \frac{1}{\omega_p^2} [(\omega^2 - c^2 k^2) \mathbf{E} + c^2 (\mathbf{k} \cdot \mathbf{E}) \mathbf{k}] \quad (10.86)$$

Then the force equation and the divergence of \mathbf{E} can be used to eliminate \mathbf{v} in order to obtain an equation for \mathbf{E} alone:

$$(\omega^2 - \omega_p^2 - c^2 k^2) \mathbf{E} + (c^2 - 3\langle u^2 \rangle)(\mathbf{k} \cdot \mathbf{E}) \mathbf{k} = 0 \quad (10.87)$$

If we write \mathbf{E} in terms of components parallel and perpendicular to \mathbf{k} :

$$\left. \begin{aligned} \mathbf{E} &= \mathbf{E}_{\parallel} + \mathbf{E}_{\perp} \\ \text{where} \quad \mathbf{E}_{\parallel} &= \left(\frac{\mathbf{k} \cdot \mathbf{E}}{k^2} \right) \mathbf{k} \end{aligned} \right\} \quad (10.88)$$

then (10.87) can be written as two equations:

$$\left. \begin{aligned} (\omega^2 - \omega_p^2 - 3\langle u^2 \rangle k^2) \mathbf{E}_{\parallel} &= 0 \\ (\omega^2 - \omega_p^2 - c^2 k^2) \mathbf{E}_{\perp} &= 0 \end{aligned} \right\} \quad (10.89)$$

The first of these results shows that the longitudinal waves satisfy the dispersion relation (10.83) already discussed, while the second shows that there are two transverse waves (two states of polarization) which have the dispersion relation:

$$\omega^2 = \omega_p^2 + c^2 k^2 \quad (10.90)$$

Equation (10.90) is just the dispersion equation for the transverse electromagnetic waves described in Section 7.5(d) from another point of view. In the absence of external fields the electrostatic oscillations and the transverse electromagnetic oscillations are not coupled together. But in the presence of an external magnetic induction, for example, the force equation has an added term involving the magnetic field and the oscillations are coupled (see Problem 10.7).

10.9 Short-Wavelength Limit for Plasma Oscillations and the Debye Screening Distance

In the discussion of plasma oscillations so far no mention has been made of the range of wave numbers over which the description in terms of collective oscillations applies. Certainly $n_0^{1/3}$ is one upper bound on the wave-number scale. A clue to a more relevant upper bound can be obtained by examining the dispersion relation (10.83) for the longitudinal oscillations. For long wavelengths the frequency of oscillation is very closely $\omega = \omega_p$. It is only for wave numbers comparable to the *Debye wave number* k_D ,

$$k_D^2 = \frac{\omega_p^2}{\langle u^2 \rangle} \quad (10.91)$$

that appreciable departures of the frequency from ω_p occur.

For wave numbers $k \ll k_D$, the phase and group velocities of the longitudinal

plasma oscillations are:

$$\left. \begin{aligned} v_p &\approx \frac{\omega_p}{k} \\ v_g &\approx \frac{3\langle u^2 \rangle}{v_p} \end{aligned} \right\} \quad (10.92)$$

From the definition of k_D we see that for such wave numbers the phase velocity is much larger than, and the group velocity much smaller than, the rms thermal velocity $\langle u^2 \rangle^{1/2}$. As the wave number increases towards k_D , the phase velocity decreases from large values down towards $\langle u^2 \rangle^{1/2}$. Consequently for wave numbers of the order of k_D the wave travels with a small enough velocity that there are appreciable numbers of electrons traveling somewhat faster than, or slower than, or at about the same speed as, the wave. The phase velocity lies in the tail of the thermal distribution. The circumstance that the wave's velocity is comparable with the electronic thermal velocities is the source of an energy-transfer mechanism which causes the destruction of the oscillation. The mechanism is the trapping of particles by the moving wave with a resultant transfer of energy out of the wave motion into the particles. The consequent damping of the wave is called *Landau damping*.

A detailed calculation of Landau damping is out of place here. But we can describe qualitatively the physical mechanism. Figure 10.11 shows a distribution of electron velocities with a certain rms spread and a Maxwellian tail out to higher velocities. For small k the phase velocity lies far out on the tail and negligible damping occurs. But as $k \rightarrow k_D$ the phase velocity lies within the tail, as shown in Fig. 10.11, with a significant number of electrons having thermal speeds comparable to v_p . There is then a velocity band Δv around $v = v_p$ where electrons are moving sufficiently slowly relative to the wave that they can be trapped in the potential troughs and carried along at velocity v_p by the wave. If there are more particles in Δv moving initially slower than v_p than there are particles moving faster (as shown in the figure), the trapping process will cause a

Fig. 10.11 Thermal velocity distribution of electrons.

net increase in the energy of the particles at the expense of the wave. This is the mechanism of Landau damping. Detailed calculations show that the damping can be expressed in terms of an imaginary part of the frequency given by

$$\text{Im } \omega \approx -\omega_p \sqrt{\frac{\pi}{8}} \left(\frac{k_D}{k}\right)^3 e^{-(k_D/2k)^2} \quad (10.93)$$

provided $k \ll k_D$. To obtain (10.93) a Maxwellian distribution of velocities was assumed. For $k \gtrsim k_D$ the damping constant is larger than given by (10.93) and rapidly becomes much larger than the real part of the frequency, as given by (10.83).

The Landau formula (10.93) shows that for $k \ll k_D$ the longitudinal plasma oscillations are virtually undamped. But the damping becomes important as soon as $k \sim k_D$ (even for $k = 0.5k_D$, $\text{Im } \omega \approx -0.7\omega_p$). For wave numbers larger than the Debye wave number the damping is so great that it is meaningless to speak of organized oscillations.

Another, rather different consideration leads to the same limiting Debye wave number as the boundary of collective oscillatory effects. We know that an electronic plasma is a collection of electrons with a uniform background of positive charge. On a very small scale of length we must describe the behavior in terms of a succession of very many two-body Coulomb collisions. But on a larger scale the electrons tend to cooperate. If a local surplus of positive charge appears anywhere, the electrons rush over to neutralize it. This collective response to charge fluctuations is what gives rise to large-scale plasma oscillations. But in addition to, or, better, because of, the collective oscillations the cooperative response of the electrons also tends to reduce the long-range nature of the Coulomb interaction between particles. An individual electron is, after all, a local fluctuation in the charge density. The surrounding electrons are repelled in such a way that they tend to screen out the Coulomb field of the chosen electron, turning it into a short-range interaction. That something like this must occur is obvious when one realizes that the only source of electrostatic interaction is the Coulomb force between the particles. If some of it is effectively taken away to cause long-wavelength collective plasma oscillations, the residue must be a sum of short-range interactions between particles.

A nonrigorous derivation of the screening effect described above was first given by Debye and Hückel in their theory of electrolytes. The basic argument is as follows. Suppose that we have a plasma with a distribution of electrons in thermal equilibrium in an electrostatic potential Φ . Then they are distributed according to the Boltzmann factor $e^{-H/KT}$ where H is the electronic Hamiltonian. The spatial density of electrons is therefore

$$n(\mathbf{x}) = n_0 e^{-(e\Phi/KT)} \quad (10.94)$$

Now we imagine a test charge Ze placed at the origin in this distribution of

electrons with its uniform background of positive ions (charge density $-en_0$). The resulting potential Φ will be determined by the Poisson equation

$$\nabla^2\Phi = -4\pi Ze \delta(\mathbf{x}) - 4\pi en_0[e^{-(e\Phi/KT)} - 1] \quad (10.95)$$

If $(e\Phi/KT)$ is assumed small, the equation can be linearized:

$$\nabla^2\Phi - k_D^2\Phi = -4\pi Ze \delta(\mathbf{x}) \quad (10.96)$$

where

$$k_D^2 = \frac{4\pi n_0 e^2}{KT} \quad (10.97)$$

is an alternative way of writing (10.91). Equation (10.96) has the spherically symmetric solution:

$$\Phi(r) = Ze \frac{e^{-k_D r}}{r} \quad (10.98)$$

showing that the electrons move in such a way as to screen out the Coulomb field of a test charge in a distance of the order of k_D^{-1} . The balance between thermal kinetic energy and electrostatic energy determines the magnitude of the screening radius. Numerically

$$k_D^{-1} = 6.91 \left(\frac{T}{n_0} \right)^{1/2} \text{ cm} \quad (10.99)$$

where T is in degrees Kelvin, and n_0 is the number of electrons per cubic centimeter. For a typical hot plasma with $T = 10^6$ °K and $n_0 = 10^{15} \text{ cm}^{-3}$, we find $k_D^{-1} \approx 2.2 \times 10^{-4} \text{ cm}$.

For the degenerate electron gas at low temperatures the Debye wave number k_D is replaced by a Fermi wave number k_F :

$$k_F \sim \frac{\omega_p}{V_F} \quad (10.100)$$

where V_F is the velocity at the surface of the Fermi sphere. This magnitude of screening radius can be deduced from a Fermi-Thomas generalization of the Debye-Hückel approach. It fits in naturally with the dispersion relation (10.83) and the mean square velocity (10.84).

The Debye-Hückel screening distance provides a natural dividing line between the small-scale collisions of pairs of particles and the large-scale collective effects such as plasma oscillations. It is a happy and not fortuitous happening that plasma oscillations of shorter wavelengths can independently be shown not to exist because of severe damping.

REFERENCES AND SUGGESTED READING

The subject of magnetohydrodynamics and plasma physics has a rapidly growing literature. Two works on magnetohydrodynamics that are coherent presentations of

the subject are

Alfvén and Fälthammar,
Cowling.

A short discussion appears in

Landau and Lifshitz, *Electrodynamics of Continuous Media*, Chapter VIII.

An engineering book with many explicit examples is

Hughes and Young.

Among corresponding books devoted mainly to the physics of plasmas are

Boyd and Sanderson,
Chandrasekhar,
Clemmow and Dougherty,
Ecker,
Holt and Haskell,
Linhart,
Simon,
Spitzer.

Radiation processes in plasmas are discussed in many of the above books, for example, in Boyd and Sanderson and in Clemmow and Dougherty. One book devoted exclusively to these questions is

Bekefi.

The application of the ideas of magnetohydrodynamics and plasma physics to magnetic and charged particle phenomena in the earth's field, in the solar system, and beyond can be found variously in

Alfvén and Fälthammar,
Hess,
Rossi and Olbert.

Controlled thermonuclear reactions are discussed, as of 1960, in

Glasstone and Lovberg,
Rose and Clark.

A more recent brief account is

R. S. Pease, *Phys. Bull.* **20**, 515 (1969).

The reader who wishes the latest on research in plasmas may consult the two series of review volumes,

Advances in Plasma Physics, eds. A. Simon and W. B. Thompson, Interscience-Wiley, New York,

Reviews of Plasma Physics, ed. M. A. Leontovich, (translation H. Lashinsky), Consultants Bureau, New York.

PROBLEMS

10.1 An infinitely long, solid, right circular, metallic cylinder has radius $(R/2)$ and conductivity σ . It is tightly surrounded by, but insulated from, a hollow cylinder of the same material of inner radius $(R/2)$ and outer radius R . Equal and opposite total currents, distributed uniformly over the cross-sectional areas, flow in the inner cylinder and in the hollow outer one. At $t=0$ the applied voltages are short-circuited.

(a) Find the distribution of magnetic induction inside the cylinders before $t=0$.

(b) Find the distribution as a function of time after $t=0$, neglecting the displacement current.

(c) What is the behavior of the magnetic induction as a function of time for long times? Define what you mean by long times.

10.2 A comparatively stable self-pinch column of plasma can be produced by trapping an axial magnetic induction inside the plasma before the pinch begins. Suppose that the plasma column initially fills a conducting tube of radius R_0 and that a uniform axial magnetic induction B_{z0} is present in the tube. Then a voltage is applied along the tube so that the axial currents flow and an azimuthal magnetic induction is built up.

(a) Show that, if quasi-equilibrium conditions apply, the pressure-balance relation can be written:

$$\left[p(r) + \frac{B_z^2}{8\pi} + \frac{B_\phi^2}{8\pi} \right]_{r_1}^{r_2} + \frac{1}{4\pi} \int_{r_1}^{r_2} \frac{B_\phi^2}{r} dr = 0$$

(b) If the plasma has a sharp boundary and such a large conductivity that currents flow only in a thin layer on the surface, show that for a quasi-static situation the radius $R(t)$ of the plasma column is given by the equation

$$\frac{R_0}{R} \ln \left(\frac{R_0}{R} \right) = \frac{1}{t_0} \int_0^t f(t) dt$$

where

$$t_0 = \frac{B_{z0} R_0}{c E_0}$$

and $E_0 f(t)$ is the applied electric field.

(c) If the initial axial field is 100 gauss, and the applied electric field has an initial value of 1 volt/cm and falls almost linearly to zero in 1 millisecond, determine the final radius if the initial radius is 50 cm. These conditions are of the same order of magnitude as those appropriate for the British toroidal apparatus (Zeta), but external inductive effects limit the pinching effect to less than the value found here. See E. P. Butt *et al.*, *Proceedings of the Second International Conference on Peaceful Uses of Atomic Energy*, Vol. 32, p. 42 (1958).

10.3 Magnetohydrodynamic waves can occur in a compressible, nonviscous, perfectly conducting fluid in a uniform static magnetic induction \mathbf{B}_0 . If the propagation direction is not parallel or perpendicular to \mathbf{B}_0 , the waves are not separated into purely longitudinal (magnetosonic) or transverse (Alfvén) waves. Let the angle between the propagation direction \mathbf{k} and the field \mathbf{B}_0 be θ .

(a) Show that there are three different waves with phase velocities given by

$$u_1^2 = (v_A \cos \theta)^2$$

$$u_{2,3}^2 = \frac{1}{2}(s^2 + v_A^2) \pm \frac{1}{2}[(s^2 + v_A^2)^2 - 4s^2 v_A^2 \cos^2 \theta]^{1/2}$$

where s is the sound velocity in the fluid, and $v_A = (B_0^2/4\pi\rho_0)^{1/2}$ is the Alfvén velocity.

(b) Find the velocity eigenvectors for the three different waves, and prove that the first (Alfvén) wave is always transverse, while the other two are neither longitudinal nor transverse.

(c) Evaluate the phase velocities and eigenvectors of the mixed waves in the approximation that $v_A \gg s$. Show that for one wave the only appreciable component of velocity is parallel to the magnetic field, while for the other the only component is perpendicular to the field and in the plane containing \mathbf{k} and \mathbf{B}_0 .

10.4 An incompressible, nonviscous, perfectly conducting fluid with constant density ρ_0 is acted upon by a gravitational potential ψ and a uniform, static magnetic induction \mathbf{B}_0 .

(a) Show that magnetohydrodynamic waves of arbitrary amplitude and form $\mathbf{B}_1(\mathbf{x}, t)$,

$\mathbf{v}(\mathbf{x}, t)$ can exist, described by the equations

$$\begin{aligned}(\mathbf{B}_0 \cdot \nabla) \mathbf{B}_1 &= \pm \sqrt{4\pi\rho_0} \frac{\partial \mathbf{B}_1}{\partial t} \\ \mathbf{B}_1 &= \pm \sqrt{4\pi\rho_0} \mathbf{v} \\ p + \rho_0 \psi + \frac{(\mathbf{B}_0 + \mathbf{B}_1)^2}{8\pi} &= \text{constant}\end{aligned}$$

(b) Suppose that at $t=0$ a certain disturbance $\mathbf{B}_1(\mathbf{x}, 0)$ exists in the fluid such that it satisfies the above equations with the upper sign. What is the behavior of the disturbance at later times?

10.5 The force equation for an electronic plasma, including a phenomenological collision term, but neglecting the hydrostatic pressure (zero temperature approximation) is

$$\frac{\partial \mathbf{v}}{\partial t} + (\mathbf{v} \cdot \nabla) \mathbf{v} = \frac{e}{m} \left(\mathbf{E} + \frac{\mathbf{v}}{c} \times \mathbf{B} \right) - \nu \mathbf{v}$$

where ν is the collision frequency.

(a) Show that in the presence of static, uniform, external, electric and magnetic fields, the linearized steady-state expression for Ohm's law becomes

$$J_i = \sum_j \sigma_{ij} E_j$$

where the conductivity tensor is

$$\sigma_{ij} = \frac{\omega_p^2}{4\pi\nu \left(1 + \frac{\omega_B^2}{\nu^2}\right)} \begin{pmatrix} 1 & \frac{\omega_B}{\nu} & 0 \\ -\frac{\omega_B}{\nu} & 1 & 0 \\ 0 & 0 & \left(1 + \frac{\omega_B^2}{\nu^2}\right) \end{pmatrix}$$

and ω_p (ω_B) is the electronic plasma (precession) frequency. The direction of \mathbf{B} is chosen as the z axis.

(b) Suppose that at $t=0$ an external electric field \mathbf{E} is suddenly applied in the x direction, there being a magnetic induction \mathbf{B} in the z direction. The current is zero at $t=0$. Find expressions for the components of the current at all times, including the transient behavior.

10.6 The effects of finite temperature on a plasma can be described approximately by means of the correlationless Boltzmann (Vlasov) equation. Let $f(\mathbf{x}, \mathbf{v}, t)$ be the distribution function for electrons of charge e and mass m in a one-component plasma. The Vlasov equation is

$$\frac{df}{dt} \equiv \frac{\partial f}{\partial t} + \mathbf{v} \cdot \nabla_x f + \mathbf{a} \cdot \nabla_v f = 0$$

where ∇_x and ∇_v are gradients with respect to coordinate and velocity, and \mathbf{a} is the acceleration of a particle. For electrostatic oscillations of the plasma $\mathbf{a} = e\mathbf{E}/m$, where

\mathbf{E} is the macroscopic electric field satisfying

$$\nabla \cdot \mathbf{E} = 4\pi e \left[\int f(\mathbf{x}, \mathbf{v}, t) d^3v - n_0 \right]$$

If $f_0(\mathbf{v})$ is the normalized equilibrium distribution of electrons

$$\left[n_0 \int f_0(\mathbf{v}) d^3v = n_0 \right]$$

(a) show that the dispersion relation for small-amplitude longitudinal plasma oscillations is

$$\frac{k^2}{\omega_p^2} = \int \frac{\mathbf{k} \cdot \nabla_{\mathbf{v}} f_0}{\mathbf{k} \cdot \mathbf{v} - \omega} d^3v$$

(b) assuming that the phase velocity of the wave is large compared to thermal velocities, show that the dispersion relation gives

$$\frac{\omega^2}{\omega_p^2} \approx 1 + 2 \frac{\langle \mathbf{k} \cdot \mathbf{v} \rangle}{\omega} + 3 \frac{\langle (\mathbf{k} \cdot \mathbf{v})^2 \rangle}{\omega^2} + \dots$$

where $\langle \rangle$ means averaged over the equilibrium distribution $f_0(\mathbf{v})$. Relate this result to that obtained in the text with the electronic fluid model.

(c) What is the meaning of the singularity in the dispersion relation when $\mathbf{k} \cdot \mathbf{v} = \omega$?

10.7 Consider the problem of waves in an electronic plasma when an external magnetic field \mathbf{B}_0 is present. Use the fluid model, neglecting the pressure term as well as collisions.

(a) Write down the linearized equations of motion and Maxwell equations, assuming all variables vary as $\exp(i\mathbf{k} \cdot \mathbf{x} - i\omega t)$.

(b) Show that the dispersion relation for the frequencies of the different modes in terms of the wave number can be written

$$\omega^2(\omega^2 - \omega_p^2)(\omega^2 - \omega_p^2 - k^2 c^2)^2 = \omega_B^2(\omega^2 - k^2 c^2)[\omega^2(\omega^2 - \omega_p^2 - k^2 c^2) + \omega_p^2 c^2(\mathbf{k} \cdot \mathbf{b})^2]$$

where \mathbf{b} is a unit vector in the direction of \mathbf{B}_0 ; ω_p and ω_B are the plasma and precession frequencies, respectively.

(c) Show that for propagation parallel to \mathbf{B}_0 the dielectric constant (7.67) is recovered.

(d) Assuming $\omega_B \ll \omega_p$, solve approximately for the various roots for the cases (i) \mathbf{k} parallel to \mathbf{b} , (ii) \mathbf{k} perpendicular to \mathbf{b} . Sketch your results for ω^2 versus k^2 in the two cases.

10.8 The dipole magnetic field of the earth is distorted by the "solar wind," a streaming interplanetary plasma consisting mostly of protons from the sun. At the earth's orbit the solar wind has a density of roughly 10 protons/cm³, with particle velocities of the order of 400 km/sec and an associated magnetic field of magnitude $(3-7) \times 10^{-5}$ gauss, these values being typical of a quiet sun.

(a) Calculate the kinetic particle pressure of the solar wind and find the distance (measured in earth radii) from the center of the earth in the magnetic equatorial plane at which the magnetic pressure of the earth's field is equal to the particle pressure. Assume that at the surface of the earth the equatorial magnetic field is 0.31 gauss. The distance where the pressures are equal marks the region where the solar wind contains and deflects the earth's magnetic field lines. Is the solar wind's own magnetic pressure important?

(b) Estimate the speed of sound (10.49) and the Alfvén speed (10.55) at the critical radius of part (a) using the earth's magnetic field there. If the particle speeds are of the order of or greater than these speeds, something like a shock phenomenon occurs at the interface. This is the cause of the "bow shock" front that is the boundary of the magnetosphere on the day side of the earth. [For details consult the papers of a symposium in *Reviews of Geophysics*, **7**, Nos. 1 and 2, (1969)].

11

Special Theory of Relativity

The special theory of relativity has, since its publication by Einstein in 1905, become a commonplace in physics, as taken for granted as Newton's laws of classical mechanics, the Maxwell equations of electromagnetism, or the Schrödinger equation of quantum mechanics. Daily it is employed by scientists in their consideration of precise atomic phenomena, in nuclear physics, and above all in high-energy physics.

The origins of the special theory of relativity lie in electromagnetism. In fact, one can say that the development of the Maxwell equations with the unification of electricity and magnetism and optics forced special relativity on us. Lorentz above all laid the groundwork with his studies of electrodynamics from 1890 onwards. Poincaré made important contributions, but it fell to Einstein to make the crucial generalization to all physical phenomena, not just electrodynamics, and to stress the far-reaching consequences of the second postulate. The special theory of relativity is now believed to apply to all forms of interaction except large-scale gravitational phenomena. It serves as a touchstone in modern physics for the possible forms of interaction between fundamental particles. Only theories consistent with special relativity need be considered. This often severely limits the possibilities.

The experimental basis and the historical development of the special theory of relativity, as well as many of its elementary consequences, are discussed in many places. A list of books and articles is given at the end of the chapter. We content ourselves with a summary of the key points and some examples of recent and definitive experimental confirmations. Then the basic kinematic results are summarized, including coordinate transformations, proper time and time dilatation, the relativistic Doppler shift, and the addition of velocities. The relativistic energy and momentum of a particle are derived from general principles, independent of the force equation. Then the idea of the Lorentz group and its mathematical description is presented and a specific representation in terms of 4×4 matrices is given. The important phenomenon of Thomas precession is then

discussed. The experimental basis for the invariance of electric charge, the covariance of electrodynamics, and the explicit transformation properties of electric and magnetic fields follow. The chapter concludes with a treatment of the relativistic equations of motion for spin and a remark on the notation and conventions of relativistic kinematics.

11.1 The Situation before 1900, Einstein's Two Postulates

In the 40 years before 1900 electromagnetism and optics were correlated and explained in triumphal fashion by the wave theory based on the Maxwell equations. Since previous experience with wave motion had always involved a medium for the propagation of waves, it was natural for physicists to assume that light needed a medium through which to propagate. In view of the known facts about light, it was necessary to assume that this medium, called the ether, permeated all space, was of negligible density, and had negligible interaction with matter. It existed solely as a vehicle for the propagation of electromagnetic waves.

The hypothesis of an ether set electromagnetic phenomena apart from the rest of physics. For a long time it had been known that the laws of mechanics were the same in different coordinate systems moving uniformly relative to one another. We say that the laws of mechanics are invariant under Galilean transformations. To emphasize the distinction between classical mechanics and electromagnetism let us consider explicitly the question of Galilean relativity for each. For two reference frames K and K' with coordinates (x, y, z, t) and (x', y', z', t') , respectively, and moving with relative velocity \mathbf{v} , the space and time coordinates in the two frames are related according to Galilean relativity by

$$\begin{aligned}\mathbf{x}' &= \mathbf{x} - \mathbf{v}t \\ t' &= t\end{aligned}\tag{11.1}$$

provided the origins in space and time are chosen suitably. As an example of a mechanical system, consider a group of particles interacting via two-body central potentials. In an obvious notation the equation of motion of the i th particle in the reference frame K' is

$$m_i \frac{d\mathbf{v}'_i}{dt'} = -\nabla'_i \sum_j V_{ij}(|\mathbf{x}'_i - \mathbf{x}'_j|)\tag{11.2}$$

From the connections (11.1) between the coordinates in K and K' it is evident that $\mathbf{v}'_i = \mathbf{v}_i - \mathbf{v}$, $\nabla'_i = \nabla_i$, $d\mathbf{v}_i/dt' = d\mathbf{v}_i/dt$, and $\mathbf{x}'_i - \mathbf{x}'_j = \mathbf{x}_i - \mathbf{x}_j$. Thus (11.2) can be transformed into

$$m_i \frac{d\mathbf{v}_i}{dt} = -\nabla_i \sum_j V_{ij}(|\mathbf{x}_i - \mathbf{x}_j|)\tag{11.3}$$

namely Newton's equation of motion in the reference frame K .

The preservation of the *form* of the equations of classical mechanics under the transformation (11.1) is in contrast to the change in form of the equations governing wave phenomena. Suppose that a field $\psi(\mathbf{x}', t')$ satisfies the wave equation,

$$\left(\sum_i \frac{\partial^2}{\partial x_i'^2} - \frac{1}{c^2} \frac{\partial^2}{\partial t'^2} \right) \psi = 0 \quad (11.4)$$

in the reference frame K' . By straightforward use of (11.1) it is found that in terms of the coordinates in the reference frame K the wave equation (11.4) becomes

$$\left(\nabla^2 - \frac{1}{c^2} \frac{\partial}{\partial t^2} - \frac{2}{c^2} \mathbf{v} \cdot \nabla \frac{\partial}{\partial t} - \frac{1}{c^2} \mathbf{v} \cdot \nabla \mathbf{v} \cdot \nabla \right) \psi = 0 \quad (11.5)$$

The form of the wave equation is not invariant under Galilean transformations. Furthermore, no kinematic transformation of ψ can restore to (11.5) the appearance of (11.4).^{*} For sound waves the lack of invariance under Galilean transformations is quite acceptable. The wind throws our voices. Sound waves are compressions and rarefactions in the air or in other materials, and the preferred reference frame K' in which (11.4) is valid is obviously the frame in which the transmitting medium is at rest.

So it also appeared for electromagnetism. The vital difference is this. Sound waves and similar wave phenomena are consequences of Galilean classical mechanics. The existence of preferred reference frames where the phenomena are simple is well understood in terms of the bulk motions of the media of propagation. For electromagnetic disturbances, on the other hand, the medium seemed truly ethereal with no manifestation or purpose other than to support the propagation.

When Einstein began to think about these matters there existed several possibilities:

1. The Maxwell equations were incorrect. The proper theory of electromagnetism was invariant under Galilean transformations.
2. Galilean relativity applied to classical mechanics, but electromagnetism had a preferred reference frame, the frame in which the luminiferous ether was at rest.

^{*} The reader might wish to ponder the differences between the wave equation and the Schrödinger equation under Galilean transformations. If in K' the Schrödinger equation reads

$$-\frac{\hbar^2}{2m} \nabla'^2 \psi' + V\psi' = i\hbar \frac{\partial \psi'}{\partial t'}$$

then in K the equation has the same form for the wave function ψ provided V is a Galilean invariant and $\psi = \psi' e^{i(m/\hbar)\mathbf{v} \cdot \mathbf{x} - i(mv^2/2\hbar)t}$. The Schrödinger equation is invariant under Galilean transformations.

3. There existed a relativity principle for both classical mechanics and electromagnetism, but it was not Galilean relativity. This would imply that the laws of mechanics were in need of modification.

The first possibility was hardly viable. The amazing successes of the Maxwell theory at the hands of Hertz, Lorentz, and others made it doubtful that the equations of electromagnetism were in serious error. The second alternative was accepted by most physicists of the time. Efforts to observe motion of the earth and its laboratories relative to the rest frame of the ether, for example, the Michelson-Morley experiment, had failed. But for this important experiment at least, the null result could be explained by the FitzGerald-Lorentz contraction hypothesis (1892) whereby objects moving at a velocity v through the ether are contracted in the direction of motion according to the formula,

$$L(v) = L_0 \sqrt{1 - \frac{v^2}{c^2}} \quad (11.6)$$

This rather unusual hypothesis apparently lies outside electromagnetism since it applies to bulk matter, but Lorentz later argued that it was rooted in electrodynamics. He and Poincaré showed that the Maxwell equations are invariant in form under what are known as Lorentz transformations (see Section 11.9) and that the contraction (11.6) held for moving charge densities, etc. in electrodynamics. With the idea that matter is electromagnetic in nature (the discovery of the electron encouraged this hypothesis) it is plausible to assume that (11.6) holds for macroscopic aggregates of electrons and atoms. Lorentz thus saved the ether hypothesis from contradiction with the Michelson-Morley experiment.

Other experiments caused embarrassment to the ether idea. Fizeau's famous experiments (1851, 1853) and later similar experiments by Michelson and Morley (1886) on the velocity of light in moving fluids could be understood only if one supposed that the ether was dragged along partially by the moving fluid, with the effectiveness of the medium in dragging the ether related to its index of refraction!

For Einstein it apparently was the implausibility of the explanation of the Fizeau observations, more than anything else, that convinced him of the unacceptability of the hypothesis of an ether. He chose the third alternative above and sought principles of relativity that would encompass classical mechanics, electrodynamics, and indeed all natural phenomena. Einstein's special theory of relativity is based on two postulates:

1. POSTULATE OF RELATIVITY

The laws of nature and the results of all experiments performed in a given frame of reference are independent of the translational motion of the system as a whole. More precisely, there exists a triply infinite set of

equivalent Euclidean reference frames moving with constant velocities in rectilinear paths relative to one another in which all physical phenomena occur in an identical manner.

For brevity these equivalent coordinate systems are called *inertial* reference frames. The postulate of relativity, phrased here more or less as by Poincaré, is consistent with all our experience in mechanics where only relative motion between bodies is relevant, and has been an explicit hypothesis in mechanics since the days of Copernicus, if not before. It is also consistent with the Michelson-Morley experiment and makes meaningless the question of detecting motion relative to the ether.

2. POSTULATE OF THE CONSTANCY OF THE SPEED OF LIGHT

The speed of light is independent of the motion of its source.

This postulate, untested when Einstein proposed it (and only verified decisively in recent years), is simplicity itself. Yet it forces on us such a radical rethinking of our ideas about space and time that it was resisted for many years.

The history of the special theory of relativity and its gradual establishment through experiments is dealt with in an extensive literature. Some references are given at the end of the chapter. Of particular note is the "Resource Letter on Relativity" published in the *American Journal of Physics*, Vol. 30, p. 462 (1962). This article contains references to books and journal articles on the history, experimental verification, and laboratory demonstrations on all aspects of special relativity.

In passing we remark that Einstein's postulates require modification of the laws of mechanics for high-speed motions. There was no evidence at the time indicating a failure of Galilean relativity for mechanics. This is basically because relativistic particles and their dynamics were unknown until the discovery of beta rays around 1900. Poincaré had speculated that the speed of light might be a limiting speed for material particles, but Einstein's special theory of relativity originated from his desire to treat all physical phenomena in the same way rather than from any need to "fix up" classical mechanics. The consequences of the special theory for mechanical concepts like momentum and energy are discussed in Section 11.5.

11.2 Some Recent Experiments

Although we appeal to the reader's prior knowledge and the existence of many books on the special theory of relativity in order to omit discussion of the standard material, there are two experiments worthy of note. One concerns the

first postulate, namely the search for an “ether drift” (evidence of motion of the laboratory relative to the ether) and the other the second postulate.

(a) *Ether Drift*

The null result of the Michelson-Morley experiment (1887) established that the velocity of the earth through the presumed ether was less than one-third of its orbital speed of approximately 3×10^4 m/sec. The experiment has been repeated many times with various modifications, always with no firm evidence of motion relative to the ether. A summary of all available evidence has been given by Shankland et al., *Rev. Mod. Phys.* **27**, 167 (1955).

As already noted, these null results can be explained without abandoning the concept of an ether by the hypothesis of the FitzGerald-Lorentz contraction. The discovery by Mössbauer (1958) of “recoilless” emission or absorption of gamma rays (called the Mössbauer effect) allows comparison of frequencies to astounding precision and gives the possibility of very accurate ether drift experiments based on the Doppler shift. In the Mössbauer effect the recoil momentum from the emission or absorption of a gamma ray is taken up by the whole solid rather than by the emitting or absorbing nucleus. This means that the *energy* of recoil is totally negligible. A gamma ray is emitted with the full energy E_0 of the nuclear transition, not the reduced energy $E \approx E_0 - E_0^2/2Mc^2$, where M is the mass of the recoiling nucleus, resulting from the recoil. Furthermore, with such recoilless transitions there are no thermal Doppler shifts. The gamma ray line thus approaches its natural shape with no broadening or shift in frequency. By employing an absorber containing the same material as the emitter, nuclear resonance absorption can be studied or used as an instrument for the study of extremely small changes of frequency.

To understand the principle of an ether drift experiment based on the Mössbauer effect, we need to recall the classic results of the Doppler shift. The phase of a plane wave is an invariant quantity, the same in all coordinate frames. This is because the elapsed phase of a wave is proportional to the number of wave crests that have passed the observer. Since this is merely a counting operation, it must be independent of coordinate frame. If there is a plane electromagnetic wave in vacuum its phase as observed in the inertial frames K and K' , connected by the Galilean coordinate transformation (11.1), is

$$\phi = \omega \left(t - \frac{\mathbf{n} \cdot \mathbf{x}}{c} \right) = \omega' \left(t' - \frac{\mathbf{n}' \cdot \mathbf{x}'}{c'} \right) \quad (11.7)$$

If t and \mathbf{x} are expressed in terms of t' and \mathbf{x}' from (11.1), we obtain

$$\omega \left[t' \left(1 - \frac{\mathbf{n} \cdot \mathbf{v}}{c} \right) - \frac{\mathbf{n} \cdot \mathbf{x}'}{c} \right] = \omega' \left(t' - \frac{\mathbf{n}' \cdot \mathbf{x}'}{c'} \right)$$

Since this equality must hold for all t' and \mathbf{x}' it is necessary that the coefficients of

t' , x'_1 , x'_2 , x'_3 on both sides be separately equal. We therefore find

$$\left. \begin{aligned} \mathbf{n} &= \mathbf{n}' \\ \omega' &= \omega \left(1 - \frac{\mathbf{n} \cdot \mathbf{v}}{c} \right) \\ c' &= c - \mathbf{n} \cdot \mathbf{v} \end{aligned} \right\} \quad (11.8)$$

These are the standard Doppler shift formulas of Galilean relativity.

The unit wave normal \mathbf{n} is seen from (11.8) to be an invariant, the same in all inertial frames. The direction of energy flow changes, however, from frame to frame. To see this consider the segments of a plane wave sketched in Fig. 11.1. The segments can be thought of as schematic representations of wave packets. At $t=t'=0$ the center of the segment is at the point A in both K and K' . If inertial frame K is the preferred reference frame (ether at rest) the wave packet moves in the direction \mathbf{n} , arriving after one unit of time at the point B in frame

Fig. 11.1

K. The distance AB is equal to c . In frame K' the center of the wave packet arrives at the point B' after one unit of time. Because of the Galilean transformation of coordinates (11.1) the point B' differs from B by a vectorial amount $-\mathbf{v}$, as indicated in the bottom half of Fig. 11.1. The direction of motion of the wave packet, assumed to be the direction of energy flow, is thus not parallel to \mathbf{n} in K' , but along a unit vector \mathbf{m} shown in Fig. 11.1 and specified by

$$\mathbf{m} = \frac{c\mathbf{n} - \mathbf{v}}{|c\mathbf{n} - \mathbf{v}|} \quad (11.9)$$

Since the experiments involve photon propagation in the laboratory, it is convenient to have the Doppler formulas (11.8) expressed in terms of the \mathbf{m} appropriate to the laboratory rather than \mathbf{n} . It is sufficient to have \mathbf{n} in terms of \mathbf{m} correct to first order in v/c . From (11.9) we find

$$\mathbf{n} \approx \left(1 - \frac{\mathbf{m} \cdot \mathbf{v}_0}{c}\right) \mathbf{m} + \frac{\mathbf{v}_0}{c} \quad (11.10)$$

where \mathbf{v}_0 is the velocity of the laboratory relative to the ether rest frame.

Consider now a plane wave whose frequency is ω in the ether rest frame, ω_0 in the laboratory, and ω_1 in an inertial frame K_1 moving with a velocity $\mathbf{v}_1 = \mathbf{u}_1 + \mathbf{v}_0$ relative to the ether rest frame. From (11.8) the observed frequencies are

$$\begin{aligned} \omega_1 &= \omega \left(1 - \frac{\mathbf{n} \cdot \mathbf{v}_1}{c}\right) \\ \omega_0 &= \omega \left(1 - \frac{\mathbf{n} \cdot \mathbf{v}_0}{c}\right) \end{aligned}$$

If ω_1 is expressed in terms of the laboratory frequency ω_0 and the wave normal \mathbf{n} is eliminated by means of (11.10), the result, correct to order v^2/c^2 , is easily shown to be

$$\omega_1 \approx \omega_0 \left[1 - \frac{\mathbf{u}_1}{c} \cdot \left(\mathbf{m} + \frac{\mathbf{v}_0}{c}\right)\right] \quad (11.11)$$

where \mathbf{u}_1 is the velocity of the frame K_1 relative to the laboratory, \mathbf{m} is the direction of energy propagation in the laboratory, ω_0 is the frequency of the wave in the laboratory, and \mathbf{v}_0 is the velocity of the laboratory with respect to the ether.

Equation (11.11) forms the basis of the analysis of the Mössbauer ether drift experiments. It is a consequence of the validity of the wave equation in the ether rest frame and Galilean relativity to transform to other inertial frames. Since it involves \mathbf{v}_0 , it obviously predicts an ether drift effect. Consider two Mössbauer systems, one an emitter and the other an absorber, moving with velocities \mathbf{u}_1 and \mathbf{u}_2 in the laboratory. From (11.11) the difference in frequency between emitter and absorber is

$$\frac{\omega_1 - \omega_2}{\omega_0} = \frac{1}{c} (\mathbf{u}_2 - \mathbf{u}_1) \cdot \left(\mathbf{m} + \frac{\mathbf{v}_0}{c}\right)$$

Fig. 11.2

If the emitter and absorber are located on the opposite ends of a rod of length $2R$ that is rotated about its center with angular velocity Ω , as indicated in Fig. 11.2, then $(\mathbf{u}_2 - \mathbf{u}_1) \cdot \mathbf{m} = 0$ and the fractional frequency difference is

$$\frac{\omega_1 - \omega_2}{\omega_0} = \frac{2\Omega R}{c^2} \sin \Omega t \cdot |(\mathbf{v}_0)_\perp| \quad (11.12)$$

where $(\mathbf{v}_0)_\perp$ is the component of \mathbf{v}_0 perpendicular to the axis of rotation.

A resonant absorption experiment of this type was performed in 1963 in Birmingham.* The Mössbauer line was the 14.4 keV gamma ray in ^{57}Fe , following the β^+ decay of ^{57}Co . The isotope ^{57}Fe is stable and occurs with a natural abundance of 2.2 per cent; the absorber was made with iron enriched to 52 per cent in ^{57}Fe . The cobalt source was implanted in ^{56}Fe . The emitter and absorber foils were located as in Fig. 11.2 with $R \approx 4$ cm. The observed fractional width of the Mössbauer line was $\Delta\omega/\omega \approx 2 \times 10^{-12}$. Counters fixed in the laboratory and located symmetrically along a diameter of the circle in the plane of the source and absorber recorded the gamma rays transmitted through the absorber. Two rotational speeds, $\Omega_L = 1257 \text{ sec}^{-1}$ and $\Omega_H = 7728 \text{ sec}^{-1}$, were alternated during each four-hour cycle that data were taken and a diurnal effect connected to the earth's rotation was sought. From (11.12) it can be seen that with $\Omega \sim 6000 \text{ sec}^{-1}$ and $R = 4$ cm, an ether drift velocity of 200 m/sec would produce a total change of frequency of the magnitude of the Mössbauer line width. The data showed no diurnal change in transmission to an accuracy of one or two per cent. The authors conclude that the magnitude of the component of \mathbf{v}_0 past the earth in a plane perpendicular to the earth's axis of rotation is $|(\mathbf{v}_0)_\perp| = 1.6 \pm 2.8 \text{ m/sec}$, a null result. An improved experiment along the same lines in 1970 gave a limit of 5 cm/sec (see Isaak, *op. cit.*).

* D. C. Champeney, G. R. Isaak, and A. M. Khan, *Phys. Letters* **7**, 241 (1963). See also G. R. Isaak, *Phys. Bull.* **21**, 255 (1970).

A conceptually similar experiment was performed in 1958 using ammonia masers.* The ammonia molecules have a well-defined direction and nonzero speeds when they enter the maser cavity. According to (11.11) there is therefore a shift in the frequency. If the frequencies of two masers whose ammonia molecules travel in opposite directions are compared, there should be an observable beat frequency. Furthermore, if the two masers are rotated together through 180° , the beat frequency should change by $\Delta\omega/\omega_0 = 4 |\mathbf{u}_{\text{mol}} \cdot \mathbf{v}_0|/c^2$. The null result of this experiment set the component of ether drift velocity at less than 30 m/sec.

These two Doppler shift experiments set observable ether drift speed limits 6000 and 1000 times smaller than the speed of the earth in its orbit and make it quite implausible that we can ever detect any motion relative to some "absolute" reference frame.

(b) Speed of Light from a Moving Source

The second postulate of Einstein, that the speed of light is independent of the motion of the source, destroys the concept of time as a universal variable independent of the spatial coordinates. Because this was a revolutionary and unpalatable idea, many attempts were made to invent theories that would explain all the observed facts without this assumption. The most notable and resilient scheme was Ritz's version of electrodynamics (1908–1911). Ritz kept the two homogeneous Maxwell equations intact, but modified the equations involving the sources in such a way that the speed of light was equal to c only when measured relative to the source. The Ritz theory is in accord with observation for the aberration of star positions, the Fizeau experiments, and the original Michelson-Morley experiment. It is customary, however, to cite Michelson-Morley experiments performed with extraterrestrial light sources (sun or star light) and light from binary stars as establishing the second postulate and ruling out Ritz's theory.

It seems clear that most of the early evidence for the second postulate is invalid because of the interaction of the radiation with the matter through which it passes before detection.† The phenomenon is encapsulated mathematically in the *extinction theorem* of Ewald (1912) and Oseen (1915). The theorem (see *Born and Wolf*, pp. 100 ff or *Rosenfeld*, pp. 105 ff) states that if an incident electromagnetic wave traveling with a speed c appropriate to vacuum enters a dispersive medium, its fields are cancelled by part of the fields of the induced

* C. J. Cedarholm, G. F. Bland, B. L. Havens, and C. H. Townes, *Phys. Rev. Letters* **1**, 342 (1958). See also T. S. Jaseja, A. Javan, J. Murray, and C. H. Townes, *Phys. Rev.* **133**, A1221 (1964).

† See the papers of criticism by J. G. Fox, *Am. J. Phys.* **30**, 297 (1962), *Am. J. Phys.* **33**, 1 (1965), *J. Opt. Soc.* **57**, 967 (1967). The second paper cited is a detailed discussion of Ritz's emission theory and a critique of the various arguments against it. See also T. Alvager, A. Nilsson, and J. Kjellman, *Arkiv f. Fys.* **26**, 209 (1963).

dipoles (macroscopically by the polarization \mathbf{P}) and replaced by another wave propagating with a phase velocity characteristic of the medium. *The incident wave is extinguished by interference and replaced by another.* The mathematical analysis shows that for *harmonic time dependence* the cancellation of the incident vacuum fields inside the medium is caused by the dipoles on the *boundary* of the medium. For the physical circumstance of a wave train arriving at the boundary and beginning to propagate in the medium it is plausible that the extinction of the incident wave and its replacement by a wave appropriate to the medium occurs over a finite distance X . Furthermore, X must be of the order of the distance required for the vacuum wave and the medium wave to get significantly out of phase because of their different phase velocities. Since the phase difference at frequency ω is $\Delta\phi = \omega(n-1)x/c$, where n is the index of refraction, we define the *extinction theorem distance* X to be

$$X = \frac{c}{\omega |n-1|} = \frac{\lambda}{2\pi |n-1|} \quad (11.13)$$

where λ is the free-space wavelength. The reader should note carefully that X is *not* the extinction or attenuation coefficient (or its reciprocal) of (9.113). Here we are concerned with phase, not absorption.

For orientation, we note that for glasses ($n \approx 1.5$) and visible light ($\lambda \approx 6000 \text{ \AA}$), $X \approx 2 \times 10^{-5} \text{ cm}$. For air at N.T.P. ($n-1 \approx 2.8 \times 10^{-4}$) and the same wavelength, $X \approx 0.04 \text{ cm}$. For more energetic photons (from above the K -shell binding energy to several MeV gammas) the index of refraction can be approximated by

$$n-1 \approx -\frac{2\pi}{k^2} \cdot \frac{Ne^2}{mc^2}$$

where N is the total number of *electrons* per unit volume. With this approximation for n , the extinction distance is

$$X \approx (\lambda r_0 N)^{-1}$$

where $r_0 = e^2/mc^2 = 2.82 \times 10^{-13} \text{ cm}$ is the classical electron radius [and the negative of the forward (Thomson) scattering amplitude]. With a 1 MeV gamma ray in air at N.T.P., for example, we find $X \approx 73 \text{ cm}$. Of relevance for astronomical situations is the estimate $X \approx 0.06 N^{-1}$ light years for visible light. Studies of the dispersion of pulsar radiation indicate that in interstellar space $\langle N \rangle \approx 0.03 \text{ cm}^{-3}$ and, hence the conclusion that for the propagation of visible light through the galaxy $X \sim 2$ light years.

From the various estimates of X it can be seen that whatever the speed of light as it leaves its source an intervening medium can easily replace it with a disturbance of the same frequency but moving with a phase velocity characteristic of the medium at rest. Observers at rest relative to the medium will then measure a speed of light equal to c , after corrections for the optical properties of

the medium. The motion of the source and the speed of light relative to it are irrelevant. As discussed in detail by Fox (*op. cit.*), essentially all of the older evidence and many recent experiments concerning the second postulate are vitiated by the consequences of the extinction theorem.

There are, however, some recent experiments that do not suffer from the criticism of Fox. The most definitive is a beautiful experiment performed at CERN, Geneva, Switzerland in 1964.* The speed of 6 GeV photons produced in the decay of very energetic neutral pions was measured by time of flight over paths up to 80 meters. The pions were produced by bombardment of a beryllium target by 19.2 GeV protons and had speeds (inferred from measured speeds of charged pions produced in the same bombardment) of $0.99975c$. The timing was done by utilizing the r - f structure of the beam. Within experimental error it was found that the speed of the photons emitted by the extremely rapidly moving source was equal to c . If the observed speed is written as $c' = c + kv$, where v is the speed of the source, the experiment showed $k = (0 \pm 1.3) \times 10^{-4}$. The appropriate value of X for 6 GeV photons is not totally clear, but it is obviously considerably larger than 100 meters (the simple formula given above yields $X = 5 \times 10^3$ meters).

The CERN experiment establishes conclusively and on a laboratory scale the validity of the second postulate of the special theory of relativity.

(c) Frequency Dependence of the Speed of Light in Vacuum

The speed of light is known to an accuracy of a few parts in 10^9 from measurements at infrared frequencies and lesser accuracy at higher frequencies. One can ask whether there is any evidence for a frequency dependence of the speed of electromagnetic waves in vacuum. One possible source of variation is attributable to a photon mass. The group velocity in this case is

$$c(\omega) = c \left(1 - \frac{\omega_0^2}{\omega^2} \right)^{1/2}$$

where the photon rest energy is $\hbar\omega_0$. As discussed in the Introduction, the mere existence of normal modes in the earth-ionosphere resonant cavity sets a limit of $\omega_0 < 10c/R$ where R is the radius of the earth. From radio frequencies ($\omega \sim 10^8 \text{ sec}^{-1}$) to $\omega \rightarrow \infty$, the change in velocity of propagation from a photon mass is therefore less than $\Delta c/c \approx 10^{-10}$.

Another source of frequency variation in the speed of light is dispersion of the vacuum, a concept lying outside special relativity but occurring in models with a discrete space-time. The discovery of pulsars make it possible to test this idea with high precision. Pulsar observations cover at least 13 decades of frequency, with any one observing apparatus having a certain "window" in the frequency

* T. Alvager, J. M. Bailey, F. J. M. Farley, J. Kjellman, and I. Wallin, *Phys. Letters* **12**, 260 (1964) and *Arkiv f. Fys.* **31**, 145 (1965).

spectrum. The quite small time duration of the pulse from some pulsars permits a simple estimate for the upper limit of variation on the speed of light for two frequencies ω_1 and ω_2 inside the frequency window of each apparatus:

$$\left| \frac{c(\omega_1) - c(\omega_2)}{c} \right| \leq \frac{c \Delta t}{D}$$

where Δt is the pulse duration and D is the distance from the source to observer. For the Crab pulsar Np 0532, $\Delta t \approx 3 \times 10^{-3}$ sec and $D \approx 6 \times 10^3$ light years so that $(c \Delta t/D) \approx 1.7 \times 10^{-14}$. Various overlapping observations from $\sim 4 \times 10^8$ Hz through the optical region and up to photon energies of 1 MeV indicate constancy of the speed at the level of $\Delta c/c < 10^{-14}$ by this simple estimation.* For higher energies, a recent experiment at the Stanford Linear Accelerator† compared the speed of 7 GeV photons with that of visible light and found $\Delta c/c < 10^{-5}$. Up to very high energies, then, there is no evidence for dispersion of the vacuum. The speed of light is a universal constant, independent of frequency.

11.3 Lorentz Transformations and Basic Kinematic Results of Special Relativity

As is well known, the constancy of the velocity of light, independent of the motion of the source, gives rise to the relations between space and time coordinates in different inertial reference frames known as Lorentz transformations. We derive these results in a more formal manner in Section 11.7, but for the present summarize the elementary derivation and important consequences, omitting the details that can be found in the many textbooks on relativity. The reader who wishes more than a reminder can consult the books listed at the end of the chapter.

(a) Simple Lorentz Transformation of Coordinates

Consider two inertial reference frames K and K' with a relative velocity v between them. The time and space coordinates of a point are (t, x, y, z) and (t', x', y', z') in the frames K and K' , respectively. The coordinate axes in the two frames are parallel and oriented so that the frame K' is moving in the positive z direction with speed v , as viewed from K . For simplicity, let the origins of the coordinates in K and K' be coincident at $t = t' = 0$. If a light source at rest at the origin in K (and so moving with a speed v in the negative z direction, as seen from K') is flashed on and off rapidly at $t = t' = 0$, Einstein's second postulate implies that observers in *both* K and K' will see a spherical shell of radiation expanding outwards from the respective origins with speed c . The wave front reaches a

* J. M. Rawls, *Phys. Rev.* **D5**, 487 (1972).

† B. C. Brown et al., *Phys. Rev. Letters* **30**, 763 (1973).

point (x, y, z) in the frame K at a time t given by the equation,

$$c^2 t^2 - (x^2 + y^2 + z^2) = 0 \quad (11.14)$$

Similarly, in the frame K' the wave front is specified by

$$c^2 t'^2 - (x'^2 + y'^2 + z'^2) = 0 \quad (11.14^1)$$

With the assumption that space-time is homogeneous and isotropic, as implied by the first postulate, the connection between the two sets of coordinates is linear. The quadratic forms (11.14) and (11.14¹) are then related by

$$c^2 t'^2 - (x'^2 + y'^2 + z'^2) = \lambda^2 [c^2 t^2 - (x^2 + y^2 + z^2)] \quad (11.15)$$

where $\lambda = \lambda(\mathbf{v})$ is a possible change of scale between frames. With the choice of orientation of axes and considerations of the inverse transformation from K' to K it is straightforward to show that $\lambda(v) = 1$ for all v and that the time and space coordinates in K' are related to those in K by the *Lorentz transformation*

$$\left. \begin{aligned} x'_0 &= \gamma(x_0 - \beta x_1) \\ x'_1 &= \gamma(x_1 - \beta x_0) \\ x'_2 &= x_2 \\ x'_3 &= x_3 \end{aligned} \right\} \quad (11.16)$$

where we have introduced the suggestive notation $x_0 = ct$, $x_1 = z$, $x_2 = x$, $x_3 = y$ and also the convenient symbols,

$$\begin{aligned} \beta &= \frac{\mathbf{v}}{c}, & \beta &= |\beta| \\ \gamma &= (1 - \beta^2)^{-1/2} \end{aligned} \quad (11.17)$$

The inverse Lorentz transformation is

$$\left. \begin{aligned} x_0 &= \gamma(x'_0 + \beta x'_1) \\ x_1 &= \gamma(x'_1 + \beta x'_0) \\ x_2 &= x'_2 \\ x_3 &= x'_3 \end{aligned} \right\} \quad (11.18)$$

It can be found from (11.16) by direct calculation, but we know from the first postulate that it must result from (11.16) by interchange of primed and unprimed variables along with a change in the sign of β . According to (11.16) or (11.18) the coordinates perpendicular to the direction of relative motion are unchanged while the parallel coordinate *and the time* are transformed. This can be contrasted with the Galilean transformation (11.1).

Equations (11.16) and (11.17) describe the special circumstance of a Lorentz transformation from one frame to another moving with velocity \mathbf{v} parallel to the

x_1 axis. If the axes in K and K' remain parallel, but the velocity \mathbf{v} of the frame K' in frame K is in an arbitrary direction, the generalization of (11.16) is

$$\left. \begin{aligned} x'_0 &= \gamma(x_0 - \boldsymbol{\beta} \cdot \mathbf{x}) \\ \mathbf{x}' &= \mathbf{x} + \frac{(\gamma - 1)}{\beta^2} (\boldsymbol{\beta} \cdot \mathbf{x}) \boldsymbol{\beta} - \gamma \boldsymbol{\beta} x_0 \end{aligned} \right\} \quad (11.19)$$

The first equation here follows almost trivially from the first equation in (11.16). The second appears somewhat complicated, but is really only the sorting out of components of \mathbf{x} and \mathbf{x}' parallel and perpendicular to \mathbf{v} for separate treatment in accord with (11.16).

The connection between β and γ given in (11.17) and the ranges $0 \leq \beta \leq 1$, $1 \leq \gamma \leq \infty$ allow the alternative parametrization,

$$\text{and so} \quad \left. \begin{aligned} \beta &= \tanh \zeta \\ \gamma &= \cosh \zeta \\ \gamma \beta &= \sinh \zeta \end{aligned} \right\} \quad (11.20)$$

where ζ is known as the *boost parameter* or *rapidity*. In terms of ζ the first two equations of (11.16) become

$$\begin{aligned} x'_0 &= x_0 \cosh \zeta - x_1 \sinh \zeta \\ x'_1 &= -x_0 \sinh \zeta + x_1 \cosh \zeta \end{aligned} \quad (11.21)$$

The structure of these equations is reminiscent of a rotation of coordinates, but with hyperbolic functions instead of circular, basically because of the relative negative sign between the space and time terms in (11.14) [see Section 11.7 and (11.95)].

(b) Four-Vectors

The Lorentz transformation (11.16), or more generally (11.19), describes the transformation of the coordinates of a point from one inertial frame to another. Just as for rotations in three dimensions, the basic transformation law is defined in terms of the coordinates of a point. In three dimensions we call \mathbf{x} a vector and speak of x_1, x_2, x_3 as the components of a vector. We designate by the same name any three physical quantities that transform under rotations in the same way as the components of \mathbf{x} . It is natural therefore to anticipate that there are numerous physical quantities that transform under Lorentz transformations in the same manner as the time and space coordinates of a point. By analogy we speak of *4-vectors*. The coordinate 4-vector is (x_0, x_1, x_2, x_3) ; we designate the components of an arbitrary 4-vector similarly as (A_0, A_1, A_2, A_3) ,* where A_1, A_2, A_3

* Because we are deferring the explicit algebraic treatment of the Lorentz group to Section 11.7, we do not write a single symbol for this 4-vector. As written, they are the components of the contravariant 4-vector A^α .

are the components of a 3-vector \mathbf{A} . The Lorentz transformation law equivalent to (11.16) for an arbitrary 4-vector is

$$\left. \begin{aligned} A'_0 &= \gamma(A_0 - \boldsymbol{\beta} \cdot \mathbf{A}) \\ A'_\parallel &= \gamma(A_\parallel - \beta A_0) \\ \mathbf{A}'_\perp &= \mathbf{A}_\perp \end{aligned} \right\} \quad (11.22)$$

where the parallel and perpendicular signs indicate components relative to the velocity $\mathbf{v} = c\boldsymbol{\beta}$. The invariance from one inertial frame to another embodied through the second postulate in (11.15) has its counterpart for any 4-vector in the invariance,

$$A_0'^2 - |\mathbf{A}'|^2 = A_0^2 - |\mathbf{A}|^2 \quad (11.23)$$

where the components (A'_0, \mathbf{A}') and (A_0, \mathbf{A}) refer to any two inertial reference frames. For two 4-vectors (A_0, A_1, A_2, A_3) and (B_0, B_1, B_2, B_3) the “scalar product” is an invariant, that is,

$$A'_0 B'_0 - \mathbf{A}' \cdot \mathbf{B}' = A_0 B_0 - \mathbf{A} \cdot \mathbf{B} \quad (11.24)$$

This result can be verified by explicit construction of the left-hand side, using (11.22) for the primed components, or using (11.23) for the sum of two 4-vectors. It is the Lorentz transformation analogue of the invariance of $\mathbf{A} \cdot \mathbf{B}$ under rotations in three dimensions.

(c) Light Cone, Proper Time, and Time Dilation

A fruitful concept in special relativity is the idea of the light cone and “space-like” and “time-like” separations between two events. Consider Fig. 11.3, in which the time axis (actually ct) is vertical and the space axes are perpendicular to it. For simplicity only one space dimension is shown. At $t=0$ a physical system, say a particle, is at the origin. Because the velocity of light is an upper bound on all velocities, the space-time domain can be divided into three regions by a “cone,” called the light cone, whose surface is specified by $x^2 + y^2 + z^2 = c^2 t^2$. Light signals emitted at $t=0$ from the origin would travel out the 45° lines in the figure. But any material system has a velocity less than c . Consequently as time goes on it would trace out a path, called its *world line*, inside the upper half-cone, for example, the curve OB . Since the path of the system lies inside the *upper half-cone* for times $t > 0$, that region is called the *future*. Similarly the *lower half-cone* is called the *past*. The system may have reached O by a path such as AO lying inside the lower half-cone. The shaded region outside the light cone is called *elsewhere*. A system at O can never reach or come from a point in space-time in elsewhere.

The division of space-time into the past-future region (inside the light cone) and elsewhere (outside the light cone) can be emphasized by considering the invariant separation or interval s_{12} between two events $P_1(t_1, \mathbf{x}_1)$ and $P_2(t_2, \mathbf{x}_2)$ in

Fig. 11.3 World line of a system and the light cone. The unshaded interior of the cone represents the past and the future, while the shaded region outside the cone is called “elsewhere.” A point inside (outside) the light cone is said to have a timelike (spacelike) separation from the origin.

space-time (we are reverting to t and \mathbf{x} temporarily to avoid proliferation of subscripts). The square of the invariant interval is

$$s_{12}^2 = c^2(t_1 - t_2)^2 - |\mathbf{x}_1 - \mathbf{x}_2|^2 \quad (11.25)$$

For any two events P_1 and P_2 there are three possibilities: (1) $s_{12}^2 > 0$, (2) $s_{12}^2 < 0$, (3) $s_{12}^2 = 0$. If $s_{12}^2 > 0$, the events are said to have a *timelike separation*. It is always possible to find a Lorentz transformation* to a new coordinate frame K' such that $\mathbf{x}'_1 = \mathbf{x}'_2$. Then

$$s_{12}^2 = c^2(t'_1 - t'_2)^2 > 0$$

In the frame K' the two events occur at the same space point, but are separated in time. Referring to Fig. 11.3, one point can be located at the origin and the other lies in the past or future. If $s_{12}^2 < 0$, the events are said to have a *spacelike separation*. Now it is possible to find an inertial frame K'' where $t''_1 = t''_2$. Then

$$s_{12}^2 = -|\mathbf{x}''_1 - \mathbf{x}''_2|^2 < 0$$

In K'' the two events occur at different space points at the same instant of time. In terms of Fig. 11.3, one event is at the origin, while the other lies in the elsewhere region. The final possibility, $s_{12}^2 = 0$, implies a *lightlike separation*. The events lie on the light cone with respect to each other and can be connected only by light signals.

The division of the separation of two events in space-time into two classes—spacelike separations or timelike separations with the light cone as the boundary surface between—is a Lorentz invariant one. Two events with a spacelike

* By considering equations (11.16), the reader can verify that there exists a Lorentz transformation with $\beta < 1$ provided $s_{12}^2 > 0$. Explicitly, $|\beta| = |\mathbf{x}_1 - \mathbf{x}_2|/c |t_1 - t_2|$.

separation in one coordinate system have a spacelike separation in all coordinate systems. This means that two such events cannot be causally connected. Since physical interactions propagate from one point to another with velocities no greater than that of light, only events with timelike separations can be causally related. An event at the origin in Fig. 11.3 can be influenced causally only by the events that occur in the past region of the light cone.

Another useful concept is *proper time*. Consider a system, which for definiteness we will think of as a particle, moving with an instantaneous velocity $\mathbf{u}(t)$ relative to some inertial system K . In a time interval dt its position changes by $d\mathbf{x} = \mathbf{u} dt$. From (11.25) the square of the corresponding infinitesimal invariant interval ds is

$$ds^2 = c^2 dt^2 - |d\mathbf{x}|^2 = c^2 dt^2 (1 - \beta^2)$$

where here $\beta = u/c$. In the coordinate system K' where the system is instantaneously at rest the space-time increments are $dt' \equiv d\tau$, $d\mathbf{x}' = 0$. Thus the invariant interval is $ds = c d\tau$. The increment of time $d\tau$ in the instantaneous rest frame of the system is thus a *Lorentz invariant quantity* that takes the form,

$$d\tau = dt \sqrt{1 - \beta^2(t)} = \frac{dt}{\gamma(t)} \quad (11.26)$$

The time τ is called the *proper time of the particle or system*. It is the time as seen in the rest frame of the system. From (11.26) it follows that a certain proper time interval $\tau_2 - \tau_1$ will be seen in the frame K as a time interval,

$$t_2 - t_1 = \int_{\tau_1}^{\tau_2} \frac{d\tau}{\sqrt{1 - \beta^2(\tau)}} = \int_{\tau_1}^{\tau_2} \gamma(\tau) d\tau \quad (11.27)$$

Equation (11.27) or (11.26) expresses the phenomenon known as *time dilatation*. A moving clock runs more slowly than a stationary clock. For equal time intervals in the clock's rest frame, the time intervals observed in the frame K are greater by a factor $\gamma > 1$. This paradoxical result is verified daily in high-energy physics laboratories where beams of unstable particles of known lifetimes τ_0 are transported before decay over distances many many times the upper limit on the Galilean decay distance of $c\tau_0$. For example, at the Fermi National Accelerator Laboratory charged pions with energies of 200 GeV are produced and transported 300 meters with less than 3 per cent loss because of decay. With a lifetime of $\tau_0 = 2.56 \times 10^{-8}$ sec, the Galilean decay distance is $c\tau_0 = 7.7$ meters. Without time dilatation, only $e^{-300/7.7} \approx 10^{-17}$ of the pions would survive. But at 200 GeV, $\gamma \approx 1400$ and the mean free path for pion decay is actually $\gamma c\tau_0 \approx 11$ km!

A careful test of time dilatation under controlled laboratory conditions is afforded by the study of the decay of mu-mesons orbiting at nearly constant speed in a magnetic field. Such a test, incidental to another experiment, confirms

fully the formula (11.27). [See the review by Bailey and Picasso cited at the end of Section 11.11.]

A totally different and entertaining experiment on time dilatation has been performed with macroscopic clocks of the type used as official time standards.* The motion of the clocks was relative to the earth in commercial aircraft, the very high precision of the cesium beam atomic clocks compensating for the relatively small speeds of the jet aircraft. The four clocks were flown around the world twice, once in an eastward and once in a westward sense. During the journeys logs were kept of the aircrafts' location and ground speed so that the integral in (11.27) could be calculated. Before and after each journey the clocks were compared with identical clocks at the U.S. Naval Observatory. With allowance for the earth's rotation and the gravitational "red shift" of general relativity, the average observed and calculated time differences in *nanoseconds* are -59 ± 10 and -40 ± 23 for the eastward trip and 273 ± 7 and 275 ± 21 for the westward. The kinematic effect of special relativity is comparable to the general relativistic effect. The agreement between observation and calculation establishes that people who continually fly eastward on jet aircraft age less rapidly than those of us who stay home, but not by much!

(d) Relativistic Doppler Shift

As has already been remarked in Section 11.2(a), the phase of a wave is an invariant quantity because the phase can be identified with the mere counting of wave crests in a wave train, an operation that must be the same in all inertial frames. In Section 11.2 the Galilean transformation of coordinates (11.1) was used to obtain the Galilean (nonrelativistic) Doppler shift formulas (11.8). Here we use the Lorentz transformation of coordinates (11.16) to obtain the *relativistic Doppler shift*. Consider a plane wave of frequency ω and wave vector \mathbf{k} in the inertial frame K . In the moving frame K' this wave will have, in general, a different frequency ω' and wave vector \mathbf{k}' , but the phase of the wave is an invariant:

$$\phi = \omega t - \mathbf{k} \cdot \mathbf{x} = \omega' t' - \mathbf{k}' \cdot \mathbf{x}' \quad (11.28)$$

[Parenthetically we remark that because the equations of (11.16) are linear the plane wave in K with phase ϕ indeed remains a plane wave in frame K' .] Using (11.16) and the same arguments as we did in going from (11.7) to (11.8), we find that the frequency $\omega' = ck'_0$ and wave vector \mathbf{k}' are given in terms of $\omega = ck_0$ and \mathbf{k} by

$$\left. \begin{aligned} k'_0 &= \gamma(k_0 - \boldsymbol{\beta} \cdot \mathbf{k}) \\ k'_{\parallel} &= \gamma(k_{\parallel} - \beta k_0) \\ \mathbf{k}'_{\perp} &= \mathbf{k}_{\perp} \end{aligned} \right\} \quad (11.29)$$

* J. C. Hafele and R. E. Keating, *Science* **177**, 166, 168 (1972).

The Lorentz transformation of (k_0, \mathbf{k}) has exactly the same form as for (x_0, \mathbf{x}) . The frequency and wave number of any plane wave thus form a 4-vector. The invariance (11.28) of the phase is the invariance of the “scalar product” of two 4-vectors (11.24). This correspondence is, in fact, an alternate path from (11.28) to the transformation law (11.29).

For light waves, $|\mathbf{k}| = k_0$, $|\mathbf{k}'| = k'_0$. Then the results (11.29) can be expressed in the more familiar form of the Doppler shift formulas

$$\begin{aligned}\omega' &= \gamma\omega(1 - \beta \cos \theta) \\ \tan \theta' &= \frac{\sin \theta}{\gamma(\cos \theta - \beta)}\end{aligned}\tag{11.30}$$

where θ and θ' are the angles of \mathbf{k} and \mathbf{k}' relative to the direction of \mathbf{v} . The inverse equations are obtained by interchanging primed and unprimed quantities and reversing the sign of β .

The first equation in (11.30) is the customary Doppler shift, modified by the factor of γ . Its presence shows that there is a *transverse* Doppler shift, even when $\theta = \pi/2$. This relativistic transverse Doppler shift has been observed spectroscopically with atoms in motion (Ives-Stilwell experiment, 1938). It also has been observed using a precise resonance-absorption Mössbauer experiment, with a nuclear gamma-ray source on the axis of a rapidly rotating cylinder and the absorber attached to the circumference of the cylinder.*

11.4 Addition of Velocities, Four-Velocity

The Lorentz transformation (11.16) or (11.18) for coordinates can be used to obtain the law for addition of velocities. Suppose that there is a moving point P whose velocity vector \mathbf{u}' has spherical coordinates (u', θ', ϕ') in the inertial frame K' , as shown in Fig. 11.4. The frame K' is moving with velocity $\mathbf{v} = c\boldsymbol{\beta}$ in the positive x_1 direction with respect to the inertial frame K . We wish to know the components of the velocity \mathbf{u} of the point P as seen from K . From (11.18) the differential expressions for dx_0 , dx_1 , dx_2 , dx_3 are

$$\begin{aligned}dx_0 &= \gamma_v(dx'_0 + \beta dx'_1) \\ dx_1 &= \gamma_v(dx'_1 + \beta dx'_0) \\ dx_2 &= dx'_2 \\ dx_3 &= dx'_3\end{aligned}$$

where we have put a subscript on γ in order to distinguish it below from $\gamma_u = (1 - u^2/c^2)^{-1/2}$ and $\gamma_{u'} = (1 - u'^2/c^2)^{-1/2}$. The velocity components in each frame

* H. J. Hay, J. P. Schiffer, T. E. Cranshaw, and P. A. Egelstaff, *Phys. Rev. Letters* **4**, 165 (1960). See also T. E. Cranshaw in *Proceedings of the International School of Physics, Varenna, Course XX*, 1961, Academic Press, New York (1962), p. 208.

Fig. 11.4 Addition of velocities.

are $u'_i = c \, dx'_i / dx'_0$ and $u_i = c \, dx_i / dx_0$. This means that the components of velocity transform according to

$$\left. \begin{aligned} u_{\parallel} &= \frac{u'_{\parallel} + v}{1 + \frac{\mathbf{v} \cdot \mathbf{u}'}{c^2}} \\ \mathbf{u}_{\perp} &= \frac{\mathbf{u}'_{\perp}}{\gamma_v \left(1 + \frac{\mathbf{v} \cdot \mathbf{u}'}{c^2} \right)} \end{aligned} \right\} \quad (11.31)$$

The notation u_{\parallel} and \mathbf{u}_{\perp} refers to components of velocity parallel and perpendicular, respectively, to \mathbf{v} . The magnitude of \mathbf{u} and its polar angles θ , ϕ in the frame K are easily found. Since $u_2/u'_2 = u_3/u'_3$, the azimuthal angles in the two frames are equal. Furthermore,

$$\tan \theta = \frac{u' \sin \theta'}{\gamma_v (u' \cos \theta' + v)}$$

and

$$u = \frac{\sqrt{u'^2 + v^2 + 2u'v \cos \theta' - \left(\frac{u'v \sin \theta'}{c} \right)^2}}{1 + \frac{u'v}{c^2} \cos \theta'} \quad (11.32)$$

The inverse results for \mathbf{u}' in terms of \mathbf{u} can be found, as usual, from (11.31) and

(11.32), by interchanging primed and unprimed quantities and changing the sign of v .

For speeds u' and v both small compared to c , the velocity addition law (11.31) reduces to the Galilean result, $\mathbf{u} = \mathbf{u}' + \mathbf{v}$, but if either speed is comparable to c modifications appear. It is impossible to obtain a speed greater than that of light by adding two velocities, even if each is very close to c . For the simple case of parallel velocities the addition law is

$$u = \frac{u' + v}{1 + \frac{vu'}{c^2}} \quad (11.33)$$

If $u' = c$, then $u = c$ also. This is an explicit example of Einstein's second postulate. The reader can check from the second equation in (11.32) that $u' = c$ implies $u = c$ for nonparallel velocities as well.

The formula for the addition of velocities is in accord with such observational tests as the Fizeau experiments on the speed of light in moving liquids and the aberration of star positions from the motion of the earth in orbit.

The structure of (11.31) makes it obvious that the law of transformation of velocities is not that of 4-vectors, as given by (11.22) and of which (11.16) and (11.29) are examples. There is, however, a 4-vector closely related to ordinary velocity. To exhibit this 4-vector we rewrite (11.31). From the second equation in (11.32) it can be shown directly that the factor $(1 + \mathbf{v} \cdot \mathbf{u}'/c^2)$ can be expressed alternatively through

$$\gamma_u = \gamma_v \gamma_{u'} \left(1 + \frac{\mathbf{v} \cdot \mathbf{u}'}{c^2} \right) \quad (11.34)$$

where γ_v , γ_u , $\gamma_{u'}$ are the gammas defined by (11.17) for \mathbf{v} , \mathbf{u} and \mathbf{u}' , respectively. When (11.34) is substituted into (11.31) those equations become

$$\begin{aligned} \gamma_u u_{\parallel} &= \gamma_v (\gamma_{u'} u'_{\parallel} + v \gamma_{u'}) \\ \gamma_u \mathbf{u}_{\perp} &= \gamma_{u'} \mathbf{u}'_{\perp} \end{aligned} \quad (11.35)$$

Comparison of (11.34) and (11.35) with the inverse of (11.22) suggests that *the four quantities* $(\gamma_u c, \gamma_u \mathbf{u})$ transform in the same way as (x_0, \mathbf{x}) and so form a 4-vector under Lorentz transformations. These four quantities are called the *time and space components of the 4-velocity* (U_0, \mathbf{U}) .

An alternative approach to the 4-velocity is through the concept of proper time τ . Ordinary velocity \mathbf{u} is defined as the time derivative of the coordinate $\mathbf{x}(t)$. The addition law (11.31) for velocities is not a 4-vector transformation law because time is not invariant under Lorentz transformations. But we have seen that the proper time τ is a Lorentz invariant. We can thus construct a 4-vector "velocity" by differentiation of the 4-vector (x_0, \mathbf{x}) with respect to τ instead of t .

Using (11.26) we have

$$\left. \begin{aligned} U_0 &\equiv \frac{dx_0}{d\tau} = \frac{dx_0}{dt} \frac{dt}{d\tau} = \gamma_u c \\ \mathbf{U} &\equiv \frac{d\mathbf{x}}{d\tau} = \frac{d\mathbf{x}}{dt} \frac{dt}{d\tau} = \gamma_u \mathbf{u} \end{aligned} \right\} \quad (11.36)$$

We show in the next section that the components of 4-velocity of a particle are proportional to its total energy and momentum.

11.5 Relativistic Momentum and Energy of a Particle

We next consider the relativistic generalizations of the momentum and kinetic energy of a particle. These can be obtained for charged particles from the Lorentz force equation and the transformation properties of electromagnetic fields already established by Lorentz before 1900, but it is useful to give a more general derivation based only on the laws of conservation of energy and momentum and on the kinematics of Lorentz transformations. This approach shows clearly the universality of the relationships, independent of the existence of electromagnetic interactions for the particle in question.

For a particle with speed small compared to the speed of light its momentum and energy are known to be

$$\begin{aligned} \mathbf{p} &= m\mathbf{u} \\ E &= E(0) + \frac{1}{2}mu^2 \end{aligned} \quad (11.37)$$

where m is the mass of the particle, \mathbf{u} is its velocity, and $E(0)$ is a constant identified as the rest energy of the particle. In nonrelativistic considerations the rest energies can be ignored; they contribute the same additive constant to both sides of an energy balance equation. In special relativity, however, the rest energy cannot be ignored. We will see below that it is the total energy (the sum of rest energy plus kinetic energy) of a particle that is significant.

We wish to find expressions for the momentum and energy of a particle consistent with the Lorentz transformation law (11.31) of velocities and reducing to (11.37) for nonrelativistic motion. The only possible generalizations consistent with the first postulate are

$$\begin{aligned} \mathbf{p} &= \mathcal{M}(u)\mathbf{u} \\ E &= \mathcal{E}(u) \end{aligned} \quad (11.38)$$

where $\mathcal{M}(u)$ and $\mathcal{E}(u)$ are functions of the magnitude of the velocity \mathbf{u} . Comparison with (11.37) yields the limiting values,

$$\begin{aligned} \mathcal{M}(0) &= m \\ \frac{\partial \mathcal{E}}{\partial u^2}(0) &= \frac{m}{2} \end{aligned} \quad (11.39)$$

We make the reasonable assumption that $\mathcal{M}(u)$ and $\mathcal{E}(u)$ are well-behaved monotonic functions of their arguments.

To determine the forms of $\mathcal{M}(u)$ and $\mathcal{E}(u)$ we consider the elastic collision of two *identical* particles and require that conservation of momentum and energy hold in all equivalent inertial frames, as implied by the first postulate. In particular, we consider the collision in two frames K and K' connected by a Lorentz transformation parallel to the z axis. A certain amount of algebra is unavoidable. To keep it to a minimum, two approaches are open. One is to set up the velocities and directions of the particles in such a clever way that the algebra shakes down quickly into an elegant and transparent result. The other is to pick a straightforward kinematic situation and proceed judiciously. The first approach lacks motivation. We adopt the second.

Let the inertial frame K' be the "center of mass" frame with the two identical particles having initial velocities $\mathbf{u}'_a = \mathbf{v}$, $\mathbf{u}'_b = -\mathbf{v}$ along the z axis. The particles collide and scatter, emerging with final velocities, $\mathbf{u}'_c = \mathbf{v}'$, $\mathbf{u}'_d = \mathbf{v}''$. The various velocities are indicated in Fig. 11.5. In K' the conservation equations for momentum and energy read

$$\begin{aligned}\mathbf{p}'_a + \mathbf{p}'_b &= \mathbf{p}'_c + \mathbf{p}'_d \\ E'_a + E'_b &= E'_c + E'_d\end{aligned}$$

or, with the forms (11.38),

$$\begin{aligned}\mathcal{M}(v)\mathbf{v} - \mathcal{M}(v)\mathbf{v} &= \mathcal{M}(v')\mathbf{v}' + \mathcal{M}(v'')\mathbf{v}'' \\ \mathcal{E}(v) + \mathcal{E}(v) &= \mathcal{E}(v') + \mathcal{E}(v'')\end{aligned}\tag{11.40}$$

Because the particles are identical it is necessary that $\mathcal{E}(v') = \mathcal{E}(v'')$ and, with the hypothesis of monotonic behavior of $\mathcal{E}(v)$, that $v' = v''$. The second equation in (11.40) then demands $v' = v'' = v$. The first equation requires $\mathbf{v}'' = -\mathbf{v}'$. All four velocities have the same magnitude with the final velocities equal and opposite, just as are the initial velocities. This rather obvious state of affairs is shown in the right-hand diagram of Fig. 11.6 where the scattering angle in K' is denoted by θ' .

We now consider the collision in another inertial frame K moving with a velocity $-\mathbf{v}$ in the z direction with respect to K' . From the transformation equations (11.31) for velocity it can be seen that particle b is at rest in K while

Fig. 11.5 Initial and final velocity vectors in the frame K' for the collision of two identical particles.

Fig. 11.6 Initial and final velocity vectors in frames K and K' for the collision of two identical particles. The lengths and angles of the solid lines representing the velocities correspond to $\theta' = 30^\circ$ and $\beta^2 = \frac{1}{3}$. The dashed lines in K are the results of a Galilean transformation from K' to K .

particle a is incident along the z axis with a velocity

$$\mathbf{u}_a = \frac{2\mathbf{v}}{1 + \frac{v^2}{c^2}} = \frac{2c\boldsymbol{\beta}}{1 + \beta^2} \quad (11.41)$$

where $\boldsymbol{\beta} = \mathbf{v}/c$. The velocity components of the final velocities \mathbf{u}_c and \mathbf{u}_d in K are similarly

$$\left. \begin{aligned} (\mathbf{u}_c)_x &= \frac{c\beta \sin \theta'}{\gamma(1 + \beta^2 \cos \theta')}, & (\mathbf{u}_c)_z &= \frac{c\beta(1 + \cos \theta')}{1 + \beta^2 \cos \theta'} \\ (\mathbf{u}_d)_x &= -\frac{c\beta \sin \theta'}{\gamma(1 - \beta^2 \cos \theta')}, & (\mathbf{u}_d)_z &= \frac{c\beta(1 - \cos \theta')}{1 - \beta^2 \cos \theta'} \end{aligned} \right\} \quad (11.42)$$

with $\gamma = (1 - \beta^2)^{-1/2}$.

The equations of conservation of momentum and energy in the inertial frame K read

$$\begin{aligned} \mathcal{M}(u_a)\mathbf{u}_a + \mathcal{M}(u_b)\mathbf{u}_b &= \mathcal{M}(u_c)\mathbf{u}_c + \mathcal{M}(u_d)\mathbf{u}_d \\ \mathcal{E}(u_a) + \mathcal{E}(u_b) &= \mathcal{E}(u_c) + \mathcal{E}(u_d) \end{aligned} \quad (11.43)$$

It is apparent from (11.41) and (11.42) or the left-hand diagram of Fig. 11.6 that while particle b is at rest the other three velocities are all different in general. Thus the determination of $\mathcal{M}(u)$ and $\mathcal{E}(u)$ from (11.43) seems obscure. We can, however, consider the limiting situation of a glancing collision in which θ' is very small. Then in the frame K \mathbf{u}_d will be nonrelativistic and \mathbf{u}_c will differ only slightly from \mathbf{u}_a . We can therefore make appropriate Taylor series expansions around

$\theta' = 0$ and obtain equations involving $\mathcal{M}(u)$, $\mathcal{E}(u)$, and perhaps their first derivatives. Explicitly, the x component of the momentum conservation equation in (11.43) is

$$0 = \mathcal{M}(u_c) \frac{c\beta \sin \theta'}{\gamma(1+\beta^2 \cos \theta')} - \mathcal{M}(u_d) \frac{c\beta \sin \theta'}{\gamma(1-\beta^2 \cos \theta')}.$$

Cancelling common factors and rearranging terms, we have

$$\mathcal{M}(u_c) = \left(\frac{1+\beta^2 \cos \theta'}{1-\beta^2 \cos \theta'} \right) \mathcal{M}(u_d)$$

This relation is valid for all θ' and in particular for $\theta' = 0$. Inspection of (11.42) shows that in that limit $\mathbf{u}_c = \mathbf{u}_a$, $\mathbf{u}_d = 0$. Thus we obtain

$$\mathcal{M}(u_a) = \left(\frac{1+\beta^2}{1-\beta^2} \right) \mathcal{M}(0) \quad (11.44)$$

From (11.41) it is easy to demonstrate that

$$\frac{1+\beta^2}{1-\beta^2} = \frac{1}{\sqrt{1-\frac{u_a^2}{c^2}}} \equiv \gamma_a \quad (11.45)$$

With the value $\mathcal{M}(0) = m$ from (11.39) we thus have

$$\mathcal{M}(u_a) = \gamma_a m$$

or equivalently that the momentum of a particle of mass m and velocity \mathbf{u} is

$$\mathbf{p} = \gamma m \mathbf{u} = \frac{m \mathbf{u}}{\sqrt{1-\frac{u^2}{c^2}}} \quad (11.46)$$

Determining the functional form of $\mathcal{E}(u)$ requires more than the straightforward evaluation of the conservation of energy equation at $\theta' = 0$. We must examine the equation for small θ' . From (11.43) we have

$$\mathcal{E}(u_a) + \mathcal{E}(0) = \mathcal{E}(u_c) + \mathcal{E}(u_d) \quad (11.47)$$

where u_c and u_d are functions of θ' . From (11.42) or (11.32) we find, correct to order θ'^2 inclusive,

$$\begin{aligned} u_c^2 &= u_a^2 - \frac{\eta}{\gamma_a} + 0(\eta^2) \\ u_d^2 &= \eta + 0(\eta^2) \end{aligned}$$

where γ_a is given by (11.45) and $\eta = c^2 \beta^2 \theta'^2 / (1 - \beta^2)$ is a convenient expansion parameter. We now expand both sides of (11.47) in Taylor series and equate

coefficients of different powers of η :

$$\mathcal{E}(u_a) + \mathcal{E}(0) = \mathcal{E}(u_a) + \eta \cdot \left(\frac{d\mathcal{E}(u_c)}{du_c^2} \cdot \frac{\partial u_c^2}{\partial \eta} \right)_{\eta=0} + \cdots + \mathcal{E}(0) + \eta \cdot \left(\frac{d\mathcal{E}(u_d)}{du_d^2} \cdot \frac{\partial u_d^2}{\partial \eta} \right)_{\eta=0} + \cdots$$

The zeroth order terms give an identity, but the first order terms yield

$$0 = -\frac{1}{\gamma_a^3} \frac{d\mathcal{E}(u_a)}{du_a^2} + \left(\frac{d\mathcal{E}(u_d)}{du_d^2} \right)_{u_d=0}$$

With the known nonrelativistic value of the second term from (11.39), we find

$$\frac{d\mathcal{E}(u_a)}{du_a^2} = \frac{m}{2} \gamma_a^3 = \frac{m}{2 \left(1 - \frac{u_a^2}{c^2} \right)^{3/2}}$$

Integration yields the expression,

$$\mathcal{E}(u) = \frac{mc^2}{\left(1 - \frac{u^2}{c^2} \right)^{1/2}} + [\mathcal{E}(0) - mc^2] \quad (11.48)$$

for the energy of a particle of mass m and velocity \mathbf{u} , up to an arbitrary constant of integration. Parenthetically we remark that in an elastic scattering process the conservation of energy condition can be expressed in terms of kinetic energies alone. Thus the undetermined constant in (11.48) is necessary and is not, as the reader might have conjectured, the result of our Taylor series expansions. Note that the *kinetic energy* $T(u)$ is given unambiguously by

$$T(u) \equiv \mathcal{E}(u) - \mathcal{E}(0) = mc^2 \left[\frac{1}{\left(1 - \frac{u^2}{c^2} \right)^{1/2}} - 1 \right] \quad (11.49)$$

Equations (11.46) and (11.48) are the necessary relativistic generalizations for the momentum and energy of a particle, consistent with the conservation laws and the postulates of special relativity. The only remaining question is the value of the rest energy $\mathcal{E}(0)$. We can appeal directly to experiment or we can examine the theoretical framework. First, experiment. Although $\mathcal{E}(0)$ cannot be determined from elastic scattering, it can be found from inelastic processes in which one type of particle is transformed into another or others of different masses. Decay processes are particularly transparent. Consider, for example, the decay of a neutral K -meson into two photons, $K^0 \rightarrow \gamma\gamma$. In the rest frame of the K -meson conservation of energy requires that the sum of the energies of the two photons be equal to $\mathcal{E}_K(0)$. For another decay mode of a neutral K -meson, into two pions, the kinetic energy of each pion in the K -meson's rest frame must be

$$T_\pi = \frac{1}{2} \mathcal{E}_K(0) - \mathcal{E}_\pi(0)$$

Measurement of the pion kinetic energy (11.49) and knowledge of $\mathcal{E}_K(0)$ allows determination of $\mathcal{E}_\pi(0)$. In these examples and every other case it is found that

the rest energy of a particle (or more complicated system) of mass m is given by the famous Einstein mass-energy relation,

$$\mathcal{E}(0) = mc^2 \quad (11.50)$$

Thus the second, square-bracketed, term in (11.48) is absent. The total energy of a particle of mass m and velocity \mathbf{u} is

$$E = \gamma mc^2 = \frac{mc^2}{\sqrt{1 - \frac{u^2}{c^2}}} \quad (11.51)$$

A second path to the results (11.50) and (11.51) is theoretical. Although the expressions (11.46) and (11.48) for the momentum and energy of a particle were found by applying the principles of special relativity to the conservation of energy and momentum, the properties of \mathbf{p} and E under Lorentz transformations are not yet explicit. The conservation equations are a set of four equations assumed to be valid in all equivalent inertial frames. Momentum conservation consists of three equations relating the spatial components of vectors. Within the framework of special relativity it is natural to attempt to identify the *four* equations of conservation as relations among 4-vectors. We observe that the momentum (11.46) is proportional to the spatial components of the 4-velocity (U_0, \mathbf{U}) defined in (11.36), that is, $\mathbf{p} = m\mathbf{U}$. The time component of this 4-vector is $p_0 = mU_0 = m\gamma_u c$. Comparison with (11.48) shows that the energy of a particle differs from cp_0 by an additive constant $[\mathcal{E}(0) - mc^2]$. This means that the four equations of energy and momentum conservation for an arbitrary collision process can be written as

$$\begin{aligned} \sum_{\text{initial}} (p_0)_a - \sum_{\text{final}} (p_0)_b &= \Delta_0 \\ \sum_{\text{initial}} \mathbf{p}_a - \sum_{\text{final}} \mathbf{p}_b &= \mathbf{\Delta} \end{aligned} \quad (11.52)$$

where $(\Delta_0, \mathbf{\Delta})$ is a 4-vector with $\mathbf{\Delta} = 0$ and

$$c\Delta_0 = \sum_{\text{final}} [\mathcal{E}_b(0) - m_b c^2] - \sum_{\text{initial}} [\mathcal{E}_a(0) - m_a c^2]$$

From the first postulate, (11.52) must be valid in all equivalent inertial frames. But if $\mathbf{\Delta} = 0$ in all inertial frames it can be seen from (11.22) that it is necessary that $\Delta_0 = 0$; the 4-vector $(\Delta_0, \mathbf{\Delta})$ is a null vector. If different types or numbers of particles can occur in the initial and final states of some process, the condition $\Delta_0 = 0$ can only be met by requiring that (11.50) hold for each particle separately. We are thus led to (11.51) as the correct form of the total energy.

The velocity of the particle can evidently be expressed in terms of its

momentum and energy from (11.46) and (11.51) as

$$\mathbf{u} = \frac{c^2 \mathbf{p}}{E} \quad (11.53)$$

The invariant “length” of the energy-momentum 4-vector ($p_0 = E/c$, \mathbf{p}) is

$$p_0^2 - \mathbf{p} \cdot \mathbf{p} = (mc)^2 \quad (11.54)$$

We see that the invariant property that characterizes a particle’s momentum and energy is its mass, m , sometimes called its rest mass.* Equation (11.54), combined with the conservation equations, form a powerful and elegant means of treating relativistic kinematics in collision and decay processes (see the problems at the end of the chapter). Note that (11.54) permits the energy E to be expressed in terms of the momentum as

$$E = \sqrt{c^2 p^2 + m^2 c^4} \quad (11.55)$$

The relations (11.46), (11.51), (11.53) for momentum, energy, and velocity of a particle are so universally accepted that it seems superfluous to speak of experimental tests. It is perhaps worthwhile, nevertheless, to cite some laboratory demonstrations. One is the connection between the kinetic energy (11.49) of a particle and its speed.† The speeds of electrons of known kinetic energies from 0.5 to 15 MeV (accelerated through a known voltage in a Van de Graaff generator, verified at the beam catcher by calorimetry) are measured by having bursts of electrons ($\Delta t = 3 \times 10^{-9}$ sec) travel a flight path of 8.4 meters. As the energy increases the transit time falls toward a limiting value of 2.8×10^{-8} sec in good agreement with (11.49). Verification of c as a limiting speed for material particles has been carried out for 11 GeV electrons ($\gamma \approx 2 \times 10^7$) in the Stanford experiment cited at the end of Section 11.2, where it was found that the electrons’ speed differed fractionally from c by less than 5×10^{-6} . An undergraduate experiment to verify the relation (11.55) between momentum and energy employs a simple magnet with roughly 10 cm radius of curvature for the momentum measurement and a NaI crystal for the energy measurement on beta rays.‡

The specification of the kinematic properties of a particle (velocity, momentum, energy) in any inertial frame can be accomplished by giving its mass and either its velocity \mathbf{u} or its momentum \mathbf{p} in that frame. A Lorentz transformation (11.22) of (p_0 , \mathbf{p}) gives the results in any other frame. It is sometimes convenient to use the two components of \mathbf{p} perpendicular to the z -axis and a rapidity ζ (11.20) as kinematic variables. Suppose that a particle has momentum \mathbf{p} in frame K , with transverse momentum \mathbf{p}_\perp and a z component p_\parallel . There is a unique

* Some authors define the mass of a particle to be E/c^2 , designating it as m or $m(u)$ and reserving the symbol m_0 for the rest mass. We always use the word mass for the Lorentz invariant quantity whose square appears in (11.54).

† W. Bertozzi, *Am. J. Phys.* **32**, 551 (1964).

‡ S. Parker, *Am. J. Phys.* **40**, 241 (1972).

Lorentz transformation in the z direction to a frame K' where the particle has no z component of momentum. In K' the particle has momentum and energy,

$$\mathbf{p}' = \mathbf{p}_\perp, \quad \frac{E'}{c} = \Omega = \sqrt{p_\perp^2 + m^2 c^2} \quad (11.56)$$

Let the rapidity parameter associated with the Lorentz transformation from K to K' be ζ . Then from the inverse of (11.21) the momentum components and energy of the particle in the original frame K can be written

$$\mathbf{p}_\perp, \quad p_\parallel = \Omega \sinh \zeta, \quad \frac{E}{c} = \Omega \cosh \zeta \quad (11.57)$$

with $\Omega = \sqrt{p_\perp^2 + m^2 c^2}$. The quantity Ω/c is sometimes called the transverse mass (because it depends on \mathbf{p}_\perp) or the longitudinal mass (because it is involved in a longitudinal boost). If the particle is at rest in K' , that is, $\mathbf{p}_\perp = 0$, then the expressions (11.57) become

$$p = mc \sinh \zeta, \quad E = mc^2 \cosh \zeta \quad (11.58)$$

alternatives to (11.46) and (11.51).

One convenience of $\mathbf{p}_\perp^{(i)}$ and $\zeta^{(i)}$ as kinematic variables is that a Lorentz transformation in the z direction shifts all rapidities by a constant amount, $\zeta^{(i)} \rightarrow \zeta^{(i)} - Z$, where Z is the rapidity parameter of the transformation. With these variables the configuration of particles in a collision process viewed in the laboratory frame differs only by a trivial shift of the origin of rapidity from the same process viewed in the center of mass frame.

11.6 Mathematical Properties of the Space-Time of Special Relativity

The kinematics of special relativity presented in the preceding sections can be discussed in a more profound and elegant manner that simultaneously simplifies and illuminates the theory. Three-dimensional rotations in classical and quantum mechanics can be discussed in terms of the group of transformations of the coordinates that leave the norm of the vector \mathbf{x} invariant. In the special theory of relativity, Lorentz transformations of the four-dimensional coordinates (x_0, \mathbf{x}) follow from the invariance of

$$s^2 = x_0^2 - x_1^2 - x_2^2 - x_3^2 \quad (11.59)$$

We can therefore rephrase the kinematics of special relativity as the consideration of the group of all transformations that leave s^2 invariant. Technically, this group is called the *homogeneous Lorentz group*. It contains ordinary rotations as well as the Lorentz transformations of Section 11.3. The group of transformations that leave invariant

$$s^2(\mathbf{x}, \mathbf{y}) = (x_0 - y_0)^2 - (x_1 - y_1)^2 - (x_2 - y_2)^2 - (x_3 - y_3)^2$$

is called the *inhomogeneous Lorentz group* or the *Poincaré group*. It contains translations and reflections in both space and time, as well as the transformations of the homogeneous Lorentz group. We shall restrict our discussion to the homogeneous transformations and subsequently omit the word homogeneous when referring to the Lorentz group.

From the first postulate it follows that the mathematical equations expressing the laws of nature must be *covariant*, that is, invariant in form, under the transformations of the Lorentz group. They must therefore be relations among Lorentz scalars, 4-vectors, 4-tensors, etc. defined by their transformation properties under the Lorentz group in ways analogous to the familiar specification of tensors of a given rank under three-dimensional rotations. We are thus led to consider briefly the mathematical structure of a space-time whose norm is defined by (11.59).

We begin by summarizing the elements of tensor analysis in a non-Euclidean vector space. The space-time continuum is defined in terms of a four-dimensional space with coordinates x^0, x^1, x^2, x^3 . We suppose that there is a well-defined transformation that yields new coordinates x'^0, x'^1, x'^2, x'^3 , according to some rule,

$$x'^\alpha = x'^\alpha(x^0, x^1, x^2, x^3), \quad \alpha = 0, 1, 2, 3 \quad (11.60)$$

For the moment the transformation law is not specified.

Tensors of rank k associated with the space-time point x are defined by their transformation properties under the transformation $x \rightarrow x'$. A *scalar* (tensor of rank zero) is a single quantity whose value is not changed by the transformation. The interval s^2 (11.59) is obviously a Lorentz scalar. For tensors of rank one, called *vectors*, two kinds must be distinguished. The first is called a *contravariant vector* A^α with four components A^0, A^1, A^2, A^3 that are transformed according to the rule,

$$A'^\alpha = \frac{\partial x'^\alpha}{\partial x^\beta} A^\beta \quad (11.61)$$

In this equation the derivative is computed from (11.60) and the repeated index β implies a summation over $\beta = 0, 1, 2, 3$. Thus explicitly we have

$$A'^\alpha = \frac{\partial x'^\alpha}{\partial x^0} A^0 + \frac{\partial x'^\alpha}{\partial x^1} A^1 + \frac{\partial x'^\alpha}{\partial x^2} A^2 + \frac{\partial x'^\alpha}{\partial x^3} A^3$$

We will henceforth employ this *summation convention* for repeated indices. A *covariant vector* or tensor of rank one B_α is defined by the rule,

$$B'_\alpha = \frac{\partial x^\beta}{\partial x'^\alpha} B_\beta \quad (11.62)$$

or, explicitly by

$$B'_\alpha = \frac{\partial x^0}{\partial x'^\alpha} B_0 + \frac{\partial x^1}{\partial x'^\alpha} B_1 + \frac{\partial x^2}{\partial x'^\alpha} B_2 + \frac{\partial x^3}{\partial x'^\alpha} B_3$$

The partial derivative in (11.62) is to be calculated from the inverse of (11.60) with x^β expressed as a function of x'^0, x'^1, x'^2, x'^3 .

Note that contravariant vectors have superscripts and covariant vectors have subscripts, corresponding to the presence of $\partial x'^\alpha / \partial x^\beta$ and its inverse in the rule of transformation. It can be verified from (11.61) that if the law of transformation (11.60) is linear then the coordinates x^0, x^1, x^2, x^3 form the components of a contravariant vector.

A contravariant tensor of rank two $F^{\alpha\beta}$ consists of 16 quantities that transform according to

$$F'^{\alpha\beta} = \frac{\partial x'^\alpha}{\partial x^\gamma} \frac{\partial x'^\beta}{\partial x^\delta} F^{\gamma\delta} \quad (11.63)$$

A covariant tensor of rank two $G_{\alpha\beta}$ transforms as

$$G'_{\alpha\beta} = \frac{\partial x^\gamma}{\partial x'^\alpha} \frac{\partial x^\delta}{\partial x'^\beta} G_{\gamma\delta} \quad (11.64)$$

and the mixed second rank tensor H^α_β transforms as

$$H'^\alpha_\beta = \frac{\partial x'^\alpha}{\partial x^\gamma} \frac{\partial x^\delta}{\partial x'^\beta} H^\gamma_\delta \quad (11.65)$$

The generalization to contravariant, covariant, or mixed tensors of arbitrary rank should be obvious from these examples.

The inner or scalar product of two vectors is defined as the product of the components of a covariant and a contravariant vector,

$$B \cdot A \equiv B_\alpha A^\alpha \quad (11.66)$$

With this definition the scalar product is an invariant or scalar under the transformation (11.60). This is established by considering the scalar product $B' \cdot A'$ and employing (11.61) and (11.62):

$$B' \cdot A' = \frac{\partial x^\beta}{\partial x'^\alpha} \frac{\partial x'^\alpha}{\partial x^\gamma} B_\beta A'^\gamma = \frac{\partial x^\beta}{\partial x^\gamma} B_\beta A'^\gamma = \delta^\beta_\gamma B_\beta A'^\gamma = B \cdot A$$

The inner product or contraction with respect to any pair of indices, either on the same tensor or one on one tensor and the other on another, is defined in analogy with (11.66). One index is contravariant and the other covariant always.

The above results or definitions are general. The specific geometry of the space-time of special relativity is defined by the invariant interval s^2 , (11.59). In differential form, the infinitesimal interval ds that defines the norm of our space is

$$(ds)^2 = (dx^0)^2 - (dx^1)^2 - (dx^2)^2 - (dx^3)^2 \quad (11.67)$$

Here we have used superscripts on the coordinates because of our present conventions. This *norm* or *metric* is a special case of the general differential length element,

$$(ds)^2 = g_{\alpha\beta} dx^\alpha dx^\beta \quad (11.68)$$

where $g_{\alpha\beta} = g_{\beta\alpha}$ is called the *metric tensor*. For the flat space-time of special relativity (in distinction to the curved space-time of general relativity) the metric tensor is diagonal, with elements

$$g_{00} = 1, \quad g_{11} = g_{22} = g_{33} = -1 \quad (11.69)$$

The contravariant metric tensor $g^{\alpha\beta}$ is defined as the normalized co-factor of $g_{\alpha\beta}$. For flat space-time it is the same:

$$g^{\alpha\beta} = g_{\alpha\beta} \quad (11.70)$$

Note that the contraction of the contravariant and covariant metric tensors gives the Kronecker delta in four dimensions:

$$g_{\alpha\gamma} g^{\gamma\beta} = \delta_{\alpha}^{\beta} \quad (11.71)$$

where $\delta_{\alpha}^{\beta} = 0$ for $\alpha \neq \beta$ and $\delta_{\alpha}^{\alpha} = 1$ for $\alpha = 0, 1, 2, 3$.

Comparison of the invariant length element $(ds)^2$ in (11.68) with the similarly invariant scalar product (11.66) suggests that the covariant coordinate 4-vector x_{α} can be obtained from the contravariant x^{β} by contraction with $g_{\alpha\beta}$, that is,

$$x_{\alpha} = g_{\alpha\beta} x^{\beta} \quad (11.72)$$

and its inverse,

$$x^{\alpha} = g^{\alpha\beta} x_{\beta} \quad (11.73)$$

In fact, contraction with $g_{\alpha\beta}$ or $g^{\alpha\beta}$ is the procedure for changing an index on any tensor from being contravariant to covariant, and vice versa. Thus

$$F_{\dots\alpha\dots} = g^{\alpha\beta} F_{\dots\beta\dots} \quad (11.74)$$

and

$$G_{\dots\alpha\dots} = g_{\alpha\beta} G_{\dots\beta\dots}$$

With the metric tensor (11.69) it follows that if a contravariant 4-vector has components, A^0, A^1, A^2, A^3 , its covariant partner has components, $A_0 = A^0, A_1 = -A^1, A_2 = -A^2, A_3 = -A^3$. We write this concisely as

$$A^{\alpha} = (A^0, \mathbf{A}), \quad A_{\alpha} = (A^0, -\mathbf{A}) \quad (11.75)$$

where the 3-vector \mathbf{A} has components A^1, A^2, A^3 . The scalar product (11.66) of two 4-vectors is

$$B \cdot A \equiv B_{\alpha} A^{\alpha} = B^0 A^0 - \mathbf{B} \cdot \mathbf{A}$$

in agreement with (11.24).

Consider now the partial derivative operators with respect to x^{α} and x_{α} . The transformation properties of these operators can be established directly by using the rules of implicit differentiation. For example, we have

$$\frac{\partial}{\partial x'^{\alpha}} = \frac{\partial x^{\beta}}{\partial x'^{\alpha}} \frac{\partial}{\partial x^{\beta}}$$

Comparison with (11.62) shows that *differentiation with respect to a contravariant component of the coordinate vector transforms as the component of a covariant*

vector operator. From (11.72) it follows that differentiation with respect to a covariant component gives a contravariant vector operator. We therefore employ the notation,

$$\begin{aligned}\partial^\alpha &\equiv \frac{\partial}{\partial x_\alpha} = \left(\frac{\partial}{\partial x^0}, -\nabla \right) \\ \partial_\alpha &\equiv \frac{\partial}{\partial x^\alpha} = \left(\frac{\partial}{\partial x^0}, \nabla \right)\end{aligned}\tag{11.76}$$

The 4-divergence of a 4-vector A is the invariant,

$$\partial^\alpha A_\alpha = \partial_\alpha A^\alpha = \frac{\partial A^0}{\partial x^0} + \nabla \cdot \mathbf{A}\tag{11.77}$$

an equation familiar in form from continuity of charge and current density, the Lorentz condition on the scalar and vector potentials, etc. These examples give a first inkling of how the covariance of a physical law emerges provided suitable Lorentz transformation properties are attributed to the quantities entering the equation.

The four-dimensional Laplacian operator is defined to be the invariant contraction,

$$\square \equiv \partial_\alpha \partial^\alpha = \frac{\partial^2}{\partial x^{02}} - \nabla^2\tag{11.78}$$

This is, of course, just the operator of the wave equation in vacuum.

11.7 Matrix Representation of Lorentz Transformations, Infinitesimal Generators

We now turn to the consideration of the Lorentz group of transformations. To make the manipulations explicit and less abstract, it is convenient to use a matrix representation with the components of a contravariant 4-vector forming the elements of a column vector. The coordinates x^0, x^1, x^2, x^3 thus define a coordinate vector whose representative is

$$x = \begin{pmatrix} x^0 \\ x^1 \\ x^2 \\ x^3 \end{pmatrix}\tag{11.79}$$

Matrix scalar products of 4-vectors (a, b) are defined in the usual way by summing over the products of the elements of a and b , or equivalently by matrix multiplication of the transpose of a on b :

$$(a, b) \equiv \bar{a}b\tag{11.80}$$

The metric tensor $g_{\alpha\beta}$ has as its representative the square 4×4 matrix

$$g = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix} \quad (11.81)$$

with $g^2 = I$, the 4×4 unit matrix. The covariant coordinate vector is

$$gx = \begin{pmatrix} x^0 \\ -x^1 \\ -x^2 \\ -x^3 \end{pmatrix} \quad (11.82)$$

obtained by matrix multiplication of g (11.81) on x (11.79). Note that in the present notation the scalar product (11.66) of two 4-vectors reads

$$a \cdot b = (a, gb) = (ga, b) = \tilde{a}gb \quad (11.83)$$

On the basis of arguments already presented in Section 11.3 we seek a group of linear transformations on the coordinates,

$$x' = Ax \quad (11.84)$$

where A is a square 4×4 matrix, such that the norm (x, gx) is left invariant:

$$\tilde{x}'gx' = \tilde{x}gx \quad (11.85)$$

Substitution of (11.84) into the left-hand side yields the equality,

$$\tilde{x}\tilde{A}gAx = \tilde{x}gx$$

Since this must hold for all coordinate vectors x , A must satisfy the matrix equation,

$$\tilde{A}gA = g \quad (11.86)$$

Certain properties of the transformation matrix A can be deduced immediately from (11.86). The first concerns the determinant of A . Taking the determinant of both sides of (11.86) gives us

$$\det(\tilde{A}gA) = \det g (\det A)^2 = \det g$$

Since $\det g = -1 \neq 0$, we obtain

$$\det A = \pm 1$$

There are two classes of transformations, *proper Lorentz transformations*, continuous with the identity transformation and so necessarily having $\det A = +1$, and *improper Lorentz transformations*. For *improper* transformations it is sufficient, but not necessary, to have $\det A = -1$. The fact that $\det A = \pm 1$ does not sort out unambiguously the two classes is a consequence of the indefinite metric of space-time. Two examples of improper transformations, $A = g$ (space inversion) with $\det A = -1$ and $A = -I$ (space and time inversion) with $\det A = +1$, illustrate this point.

The second property of A is the number of parameters needed to specify completely a transformation of the group. Since A and g are 4×4 matrices, (11.86) represents 16 equations for the $4^2 = 16$ elements of A . But they are not all independent because of symmetry under transposition. There are thus $16 - (1 + 2 + 3) = 10$ linearly independent equations for the 16 elements of A . This means that there are *six free parameters*—the Lorentz group is a six-parameter group. The six parameters can be conveniently thought of as (a) three parameters (e.g., Euler angles) to specify the relative orientation of the coordinate axes and (b) three parameters (e.g., components of β) to specify the relative velocity of the two inertial frames. Parenthetically we remark that for every six-parameter A giving a proper Lorentz transformation, there is an improper one represented by $-A$. From now on we consider only proper Lorentz transformations.

The explicit construction of A can proceed as follows. We make the ansatz

$$A = e^L \quad (11.87)$$

where L is a 4×4 matrix. The determinant of A is*

$$\det A = \det(e^L) = e^{\text{Tr } L}$$

If L is a real matrix, $\det A = -1$ is excluded. Furthermore, if L is traceless, then $\det A = +1$. Thus, for proper Lorentz transformations, L is a real, traceless 4×4 matrix. Equation (11.86) can be written

$$g\tilde{A}g = A^{-1} \quad (11.88)$$

From the definition (11.87) and the fact that $g^2 = I$ we have

$$\tilde{A} = e^{\tilde{L}}, \quad g\tilde{A}g = e^{g\tilde{L}g}, \quad A^{-1} = e^{-L}$$

Therefore (11.88) is equivalent to

$$g\tilde{L}g = -L$$

or

$$\tilde{L} = -gL \quad (11.89)$$

The matrix gL is thus antisymmetric. From the properties of g (11.81) it is evident that the general form of L is

$$L = \begin{pmatrix} 0 & L_{01} & L_{02} & L_{03} \\ L_{01} & 0 & L_{12} & L_{13} \\ L_{02} & -L_{12} & 0 & L_{23} \\ L_{03} & -L_{13} & -L_{23} & 0 \end{pmatrix} \quad (11.90)$$

* To prove this, note first that the value of the determinant or the trace of a matrix is unchanged by a similarity transformation. Then make such a transformation to put L in diagonal form. The matrix A will then be diagonal with elements that are the exponentials of the corresponding elements of L . The result follows immediately.

The dashed lines are inserted to set off the 3×3 antisymmetric spatial matrix corresponding to the familiar *rotations* in a fixed inertial frame from the symmetric space-time part of the matrix corresponding to Lorentz transformations or *boosts* from one inertial frame to another.

The matrix (11.90), with its six parameters is an explicit construction (through (11.87)) of the transformation matrix A . It is customary, however, to systematize L and its six parameters by introducing a set of six fundamental matrices defined by

$$S_1 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \quad S_2 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix},$$

$$S_3 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \quad (11.91)$$

$$K_1 = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & & & \\ 0 & & & \\ 0 & & & \end{pmatrix}, \quad K_2 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & & & \\ 1 & & & \\ 0 & & & \end{pmatrix}, \quad K_3 = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & & & \\ 0 & & & \\ 1 & & & \end{pmatrix}$$

The matrices S_i evidently generate rotations in three dimensions, while the matrices K_i produce boosts. For reference, we note that the squares of these six matrices are all diagonal and of the form,

$$S_1^2 = \begin{pmatrix} 0 & & & \\ & 0 & & \\ & & -1 & \\ & 0 & & -1 \end{pmatrix}, \quad S_2^2 = \begin{pmatrix} 0 & & & \\ & -1 & & \\ & & 0 & \\ 0 & & & -1 \end{pmatrix},$$

$$S_3^2 = \begin{pmatrix} 0 & & & \\ & -1 & & \\ & & -1 & \\ 0 & & & 0 \end{pmatrix} \quad (11.92)$$

$$K_1^2 = \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & 0 & \\ 0 & & & 0 \end{pmatrix}, \quad K_2^2 = \begin{pmatrix} 1 & & & \\ & 0 & & \\ & & 1 & \\ 0 & & & 0 \end{pmatrix},$$

$$K_3^2 = \begin{pmatrix} 1 & & & \\ & 0 & & \\ & & 0 & \\ 0 & & & 1 \end{pmatrix}$$

Furthermore, it can be shown that $(\epsilon \cdot \mathbf{S})^3 = -\epsilon \cdot \mathbf{S}$ and $(\epsilon' \cdot \mathbf{K})^3 = \epsilon' \cdot \mathbf{K}$ where ϵ and ϵ' are any real unit 3-vectors. Thus any power of one of the matrices can be expressed as a multiple of the matrix or its square.

The general result (11.90) for L can now be written alternatively as

$$\text{and } \left. \begin{aligned} L &= -\omega \cdot \mathbf{S} - \zeta \cdot \mathbf{K} \\ A &= e^{-\omega \cdot \mathbf{S} - \zeta \cdot \mathbf{K}} \end{aligned} \right\} \quad (11.93)$$

where ω and ζ are constant 3-vectors. The three components each of ω and ζ correspond to the six parameters of the transformation. To establish contact with previous results such as (11.16) or (11.21), we consider first a simple situation in which $\omega = 0$ and $\zeta = \zeta \epsilon_1$. Then $L = -\zeta K_1$ and with the help of (11.92) and $K_1^3 = K_1$ we find

$$A = e^L = (I - K_1^2) - K_1 \sinh \zeta + K_1^2 \cosh \zeta \quad (11.94)$$

Explicitly,

$$A = \begin{pmatrix} \cosh \zeta & -\sinh \zeta & 0 & 0 \\ -\sinh \zeta & \cosh \zeta & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \quad (11.95)$$

This matrix corresponds exactly to the transformation (11.21).^{*} If $\zeta = 0$ and $\omega = \omega \epsilon_3$, the transformation is similarly found to be

$$A = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos \omega & \sin \omega & 0 \\ 0 & -\sin \omega & \cos \omega & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \quad (11.96)$$

corresponding to a rotation of the coordinate axes in a clockwise sense around the 3-axis.

For a boost (without rotation) in an arbitrary direction,

$$A = e^{-\zeta \cdot \mathbf{K}}$$

The boost vector ζ can be written in terms of the relative velocity β as

$$\zeta = \hat{\beta} \tanh^{-1} \beta$$

where $\hat{\beta}$ is a unit vector in the direction of the relative velocity of the two inertial frames. The pure boost is then

$$A_{\text{boost}}(\beta) = e^{-\hat{\beta} \cdot \mathbf{K} \tanh^{-1} \beta} \quad (11.97)$$

^{*} The reader is reminded that in Sections 11.3, 11.4, and 11.5 no distinction is made between subscripts and superscripts. All components of vectors there are to be interpreted as contravariant components, in accordance with (11.75).

It is left as an exercise to verify that this transformation gives the explicit matrix:

$$A_{\text{boost}}(\boldsymbol{\beta}) = \begin{pmatrix} \gamma & -\gamma\beta_1 & -\gamma\beta_2 & -\gamma\beta_3 \\ -\gamma\beta_1 & 1 + \frac{(\gamma-1)\beta_1^2}{\beta^2} & \frac{(\gamma-1)\beta_1\beta_2}{\beta^2} & \frac{(\gamma-1)\beta_1\beta_3}{\beta^2} \\ -\gamma\beta_2 & \frac{(\gamma-1)\beta_1\beta_2}{\beta^2} & 1 + \frac{(\gamma-1)\beta_2^2}{\beta^2} & \frac{(\gamma-1)\beta_2\beta_3}{\beta^2} \\ -\gamma\beta_3 & \frac{(\gamma-1)\beta_1\beta_3}{\beta^2} & \frac{(\gamma-1)\beta_2\beta_3}{\beta^2} & 1 + \frac{(\gamma-1)\beta_3^2}{\beta^2} \end{pmatrix} \quad (11.98)$$

The equation $x' = A_{\text{boost}}(\boldsymbol{\beta})x$ is a matrix statement of the four equations of (11.19).

The six matrices (11.91) are a representation of the *infinitesimal generators* of the Lorentz group. Straightforward calculation shows that they satisfy the following commutation relations,

$$\left. \begin{aligned} [S_i, S_j] &= \epsilon_{ijk} S_k \\ [S_i, K_j] &= \epsilon_{ijk} K_k \\ [K_i, K_j] &= -\epsilon_{ijk} S_k \end{aligned} \right\} \quad (11.99)$$

where the commutator notation is $[A, B] \equiv AB - BA$. The first relation corresponds to the commutation relations for angular momentum, the second relation merely shows that K transforms as a vector under rotations, and the final relation shows that boosts do not in general commute. The commutation relations (11.99), with the characteristic minus sign in the last commutator, specify the algebraic structure of the Lorentz group to be $SL(2, C)$ or $O(3, 1)$.

11.8 Thomas Precession

The description of Lorentz transformations in terms of noncommuting matrices demonstrates that in general the result of successive Lorentz transformations depends upon the order in which they are performed. The commutation relations (11.99) imply that two successive Lorentz transformations are equivalent to a single Lorentz transformation plus a three-dimensional rotation. An example of the kinematic consequences of the noncommutativity of Lorentz transformations is the phenomenon known as *Thomas precession*.* To motivate the discussion we first describe the physical context.

In 1926, Uhlenbeck and Goudsmit introduced the idea of electron spin and showed that, if the electron had a g factor of 2, the anomalous Zeeman effect could be explained, as well as the existence of multiplet splittings. There was a

* L. T. Thomas, *Phil. Mag.* **3**, 1 (1927).

difficulty, however, in that the observed fine-structure intervals were only one-half the theoretically expected values. If a g factor of unity were chosen, the fine-structure intervals were given correctly, but the Zeeman effect was then the normal one. The complete explanation of spin, including correctly the g factor and the proper fine-structure interaction, came only with the relativistic electron theory of Dirac. But within the framework of an empirical spin angular momentum and a g factor of 2, Thomas showed in 1927 that the origin of the discrepancy was a relativistic kinematic effect which, when included properly, gave both the anomalous Zeeman effect and the correct fine-structure splittings. The *Thomas precession*, as it is called, also gives a qualitative explanation for a spin-orbit interaction in atomic nuclei and shows why the doublets are “inverted” in nuclei.

The Uhlenbeck-Goudsmit hypothesis was that an electron possessed a spin angular momentum \mathbf{s} (which could take on quantized values of $\pm\hbar/2$ along any axis) and a magnetic moment $\boldsymbol{\mu}$ related to \mathbf{s} by

$$\boldsymbol{\mu} = \frac{ge}{2mc} \mathbf{s} \quad (11.100)$$

where the g factor had the value $g=2$. Suppose that an electron moves with a velocity \mathbf{v} in external fields \mathbf{E} and \mathbf{B} . Then the equation of motion for its angular momentum in its rest frame is

$$\left(\frac{d\mathbf{s}}{dt}\right)_{\text{rest frame}} = \boldsymbol{\mu} \times \mathbf{B}' \quad (11.101)$$

where \mathbf{B}' is the magnetic induction in that frame. We will show in Section 11.10 that in a coordinate system moving with the electron the magnetic induction is

$$\mathbf{B}' \approx \left(\mathbf{B} - \frac{\mathbf{v}}{c} \times \mathbf{E}\right) \quad (11.102)$$

where we have neglected terms of the order of (v^2/c^2) . Then (11.101) becomes

$$\left(\frac{d\mathbf{s}}{dt}\right)_{\text{rest frame}} = \boldsymbol{\mu} \times \left(\mathbf{B} - \frac{\mathbf{v}}{c} \times \mathbf{E}\right) \quad (11.103)$$

Equation (11.103) is equivalent to an energy of interaction of the electron spin:

$$U' = -\boldsymbol{\mu} \cdot \left(\mathbf{B} - \frac{\mathbf{v}}{c} \times \mathbf{E}\right) \quad (11.104)$$

In an atom the electric force $e\mathbf{E}$ can be approximated as the negative gradient of a spherically symmetric average potential energy $V(r)$. For one-electron atoms this is, of course, exact. Thus

$$e\mathbf{E} = -\frac{\mathbf{r}}{r} \frac{dV}{dr} \quad (11.105)$$

Then the spin-interaction energy can be written

$$U' = -\frac{ge}{2mc} \mathbf{s} \cdot \mathbf{B} + \frac{g}{2m^2c^2} (\mathbf{s} \cdot \mathbf{L}) \frac{1}{r} \frac{dV}{dr} \quad (11.106)$$

where $\mathbf{L} = m(\mathbf{r} \times \mathbf{v})$ is the electron's orbital angular momentum. This interaction energy gives the anomalous Zeeman effect correctly, but has a spin-orbit interaction that is twice too large.

The error in (11.106) can be traced to the incorrectness of (11.101) as an equation of motion for the electron spin. The left-hand side of (11.101) gives the rate of change of spin in the rest frame of the electron. If, as Thomas first pointed out, that coordinate system rotates, then the total time rate of change of the spin, or more generally, any vector \mathbf{G} is given by the well known result,*

$$\left(\frac{d\mathbf{G}}{dt} \right)_{\text{nonrot}} = \left(\frac{d\mathbf{G}}{dt} \right)_{\text{rest frame}} + \boldsymbol{\omega}_T \times \mathbf{G} \quad (11.107)$$

where $\boldsymbol{\omega}_T$ is the angular velocity of rotation found by Thomas. When applied to the electron spin, (11.107) gives an equation of motion:

$$\left(\frac{ds}{dt} \right)_{\text{nonrot}} = \mathbf{s} \times \left(\frac{ge\mathbf{B}'}{2mc} - \boldsymbol{\omega}_T \right) \quad (11.108)$$

The corresponding energy of interaction is

$$U = U' + \mathbf{s} \cdot \boldsymbol{\omega}_T \quad (11.109)$$

where U' is the electromagnetic spin interaction (11.104) or (11.106).

The origin of the Thomas precessional frequency $\boldsymbol{\omega}_T$ is the acceleration experienced by the electron as it moves under the action of external forces. Consider an electron moving with velocity $\mathbf{v}(t)$ with respect to a laboratory inertial frame. The electron's rest frame of coordinates is defined as a co-moving sequence of inertial frames whose successive origins move at each instant with the velocity of the electron. Let the velocity of the rest frame with respect to the laboratory at laboratory time t be $\mathbf{v}(t) = c\boldsymbol{\beta}$, and at laboratory time $t + \delta t$ be $\mathbf{v}(t + \delta t) = c(\boldsymbol{\beta} + \delta\boldsymbol{\beta})$. The connection between the coordinates in the electron's rest frame at time t and the coordinates in the laboratory frame is

$$x' = A_{\text{boost}}(\boldsymbol{\beta})x \quad (11.110)$$

At time $t + \delta t$ the connection is

$$x'' = A_{\text{boost}}(\boldsymbol{\beta} + \delta\boldsymbol{\beta})x \quad (11.111)$$

It is important to note that these transformations of coordinate from the laboratory to the rest frame are defined here in terms of pure Lorentz boosts without rotations. We are interested in the behavior of the coordinate axes of the

* See, for example, *Goldstein*, p. 133.

electron's rest frame as a function of time. Thus we want the connection between the two sets of rest frame coordinates, x' at time t and x'' at time $t + \delta t$. This relation is

$$x'' = A_T x'$$

where

$$A_T = A_{\text{boost}}(\boldsymbol{\beta} + \delta\boldsymbol{\beta}) A_{\text{boost}}^{-1}(\boldsymbol{\beta}) = A_{\text{boost}}(\boldsymbol{\beta} + \delta\boldsymbol{\beta}) A_{\text{boost}}(-\boldsymbol{\beta}) \quad (11.112)$$

For purposes of calculating A_T a suitable choice of axes in the laboratory frame is shown in Fig. 11.7. The velocity vector $\boldsymbol{\beta}$ at time t is parallel to the 1 axis and the increment of velocity $\delta\boldsymbol{\beta}$ lies in the 1-2 plane. From (11.98) it follows that

$$A_{\text{boost}}(-\boldsymbol{\beta}) = \begin{pmatrix} \gamma & \gamma\boldsymbol{\beta} & 0 & 0 \\ \gamma\boldsymbol{\beta} & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \quad (11.113)$$

Similarly we obtain from (11.98), keeping only first order terms in $\delta\boldsymbol{\beta}$,

$$A_{\text{boost}}(\boldsymbol{\beta} + \delta\boldsymbol{\beta}) = \begin{pmatrix} \gamma + \gamma^3 \boldsymbol{\beta} \delta\boldsymbol{\beta}_1 & -(\gamma\boldsymbol{\beta} + \gamma^3 \delta\boldsymbol{\beta}_1) & -\gamma \delta\boldsymbol{\beta}_2 & 0 \\ -(\gamma\boldsymbol{\beta} + \gamma^3 \delta\boldsymbol{\beta}_1) & \gamma + \gamma^3 \boldsymbol{\beta} \delta\boldsymbol{\beta}_1 & \left(\frac{\gamma-1}{\beta}\right) \delta\boldsymbol{\beta}_2 & 0 \\ -\gamma \delta\boldsymbol{\beta}_2 & \left(\frac{\gamma-1}{\beta}\right) \delta\boldsymbol{\beta}_2 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \quad (11.114)$$

Straightforward matrix multiplication according to (11.112) yields

$$A_T = \begin{pmatrix} 1 & -\gamma^2 \delta\boldsymbol{\beta}_1 & -\gamma \delta\boldsymbol{\beta}_2 & 0 \\ -\gamma^2 \delta\boldsymbol{\beta}_1 & 1 & \left(\frac{\gamma-1}{\beta}\right) \delta\boldsymbol{\beta}_2 & 0 \\ -\gamma \delta\boldsymbol{\beta}_2 & -\left(\frac{\gamma-1}{\beta}\right) \delta\boldsymbol{\beta}_2 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \quad (11.115)$$

This represents an infinitesimal Lorentz transformation that can be written in terms of the matrices S and K as

$$A_T = I - \left(\frac{\gamma-1}{\beta^2}\right) (\boldsymbol{\beta} \times \delta\boldsymbol{\beta}) \cdot \mathbf{S} - (\gamma^2 \delta\boldsymbol{\beta}_{\parallel} + \gamma \delta\boldsymbol{\beta}_{\perp}) \cdot \mathbf{K} \quad (11.116)$$

where $\delta\boldsymbol{\beta}_{\parallel}$ and $\delta\boldsymbol{\beta}_{\perp}$ are the components of $\delta\boldsymbol{\beta}$ parallel and perpendicular to $\boldsymbol{\beta}$, respectively. To first order in $\delta\boldsymbol{\beta}$, (11.116) is equivalent to

$$A_T = A_{\text{boost}}(\Delta\boldsymbol{\beta}) R(\Delta\boldsymbol{\Omega}) = R(\Delta\boldsymbol{\Omega}) A_{\text{boost}}(\Delta\boldsymbol{\beta}) \quad (11.117)$$

Fig. 11.7

where

$$A_{\text{boost}}(\Delta\beta) = I - \Delta\beta \cdot \mathbf{K}$$

$$R(\Delta\Omega) = I - \Delta\Omega \cdot \mathbf{S}$$

are commuting infinitesimal boosts and rotations, with velocity,

$$\Delta\beta = \gamma^2 \delta\beta_{\parallel} + \gamma \delta\beta_{\perp}$$

and angle of rotation,

$$\Delta\Omega = \left(\frac{\gamma-1}{\beta^2} \right) \beta \times \delta\beta = \frac{\gamma^2}{\gamma+1} \beta \times \delta\beta$$

Thus the pure Lorentz boost (11.111) to the frame with velocity $c(\beta + \delta\beta)$ is equivalent to a boost (11.110) to a frame moving with velocity $c\beta$, followed by an infinitesimal Lorentz transformation consisting of a boost with velocity $c\Delta\beta$ and a rotation $\Delta\Omega$.

In terms of the interpretation of the moving frames as successive rest frames of the electron we do not want rotations as well as boosts. Nonrelativistic equations of motion like (11.101) can be expected to hold provided the evolution of the rest frame is described by infinitesimal boosts *without* rotations. We are thus led to consider the rest frame coordinates at time $t + \delta t$ that are given from those at time t by the boost $A_{\text{boost}}(\Delta\beta)$ instead of A_T . Denoting these coordinates by x''' , we have

$$x''' = A_{\text{boost}}(\Delta\beta)x'$$

Using (11.117), (11.112), and (11.110) we can express x''' in terms of the laboratory coordinates as

$$x''' = R(-\Delta\Omega)A_{\text{boost}}(\beta + \delta\beta)x \quad (11.118)$$

The rest system of coordinates defined by x''' is rotated by $-\Delta\Omega$ relative to the boosted laboratory axes (x''). If a physical vector \mathbf{G} has a (proper) time rate of

change $(d\mathbf{G}/d\tau)$ in the rest frame, the precession of the rest frame axes with respect to the laboratory makes the vector have a total time rate of change with respect to the laboratory axes of (11.107), with

$$\boldsymbol{\omega}_T = -\lim_{\delta t \rightarrow 0} \frac{\Delta \boldsymbol{\Omega}}{\delta t} = \frac{\gamma^2}{\gamma + 1} \frac{\mathbf{a} \times \mathbf{v}}{c^2} \quad (11.119)$$

where \mathbf{a} is the acceleration in the laboratory frame and, to be precise, $(d\mathbf{G}/dt)_{\text{rest frame}} = \gamma^{-1}(d\mathbf{G}/d\tau)_{\text{rest frame}}$.

The Thomas precession is purely kinematical in origin. If a component of acceleration exists perpendicular to \mathbf{v} , for whatever reason, then there is a Thomas precession, independent of other effects such as precession of the magnetic moment in a magnetic field.

For electrons in atoms the acceleration is caused by the screened Coulomb field (11.105). Thus the Thomas angular velocity is

$$\boldsymbol{\omega}_T \approx \frac{-1}{2c^2} \frac{\mathbf{r} \times \mathbf{v}}{m} \frac{1}{r} \frac{dV}{dr} = \frac{-1}{2m^2 c^2} \mathbf{L} \frac{1}{r} \frac{dV}{dr} \quad (11.120)$$

It is evident from (11.109) and (11.106) that the extra contribution to the energy from the Thomas precession reduces the spin-orbit coupling, yielding

$$U = -\frac{ge}{2mc} \mathbf{s} \cdot \mathbf{B} + \frac{(g-1)}{2m^2 c^2} \mathbf{s} \cdot \mathbf{L} \frac{1}{r} \frac{dV}{dr} \quad (11.121)$$

With $g=2$ the spin-orbit interaction of (11.106) is reduced by $\frac{1}{2}$ (sometimes called the *Thomas factor*), as required for the correct spin-orbit interaction energy of an atomic electron.

In atomic nuclei the nucleons experience strong accelerations because of the specifically nuclear forces. The electromagnetic forces are comparatively weak. In an approximate way one can treat the nucleons as moving separately in a short-range, spherically symmetric, attractive, potential well, $V_N(r)$. Then each nucleon will experience in addition a spin-orbit interaction given by (11.109) with the negligible electromagnetic contribution U' omitted:

$$U_N \approx \mathbf{s} \cdot \boldsymbol{\omega}_T \quad (11.122)$$

where the acceleration in $\boldsymbol{\omega}_T$ is determined by $V_N(r)$. The form of $\boldsymbol{\omega}_T$ is the same as (11.120) with V replaced by V_N . Thus the nuclear spin-orbit interaction is approximately

$$U_N \approx -\frac{1}{2M^2 c^2} \mathbf{s} \cdot \mathbf{L} \frac{1}{r} \frac{dV_N}{dr} \quad (11.123)$$

In comparing (11.123) with atomic formula (11.121) we note that both V and V_N are attractive (although V_N is much larger), so that the signs of the spin-orbit energies are opposite. This means that in nuclei the single particle levels form

“inverted” doublets. With a reasonable form for V_N , (11.123) is in qualitative agreement with the observed spin-orbit splittings in nuclei.*

The phenomenon of Thomas precession is presented from a more sophisticated point of view in Section 11.11 where the BMT equation is discussed.

11.9 Invariance of Electric Charge, Covariance of Electrodynamics

The invariance in form of the equations of electrodynamics under Lorentz transformations was shown by Lorentz and Poincaré before the formulation of the special theory of relativity. This invariance of form or *covariance* of the Maxwell and Lorentz force equations implies that the various quantities ρ , \mathbf{J} , \mathbf{E} , \mathbf{B} that enter these equations transform in well-defined ways under Lorentz transformations. Then the terms in the equations can have consistent behavior under Lorentz transformations.

Consider first the Lorentz force equation for a particle of charge q ,

$$\frac{d\mathbf{p}}{dt} = q \left(\mathbf{E} + \frac{\mathbf{v}}{c} \times \mathbf{B} \right) \quad (11.124)$$

We know that \mathbf{p} transforms as the space part of the 4-vector of energy and momentum,

$$p^\alpha = (p_0, \mathbf{p}) = m(U_0, \mathbf{U})$$

where $p_0 = E/c$ and U^α is the 4-velocity (11.36). If we use the proper time τ (11.26) instead of t for differentiation, (11.124) can be written

$$\frac{d\mathbf{p}}{d\tau} = \frac{q}{c} (U_0 \mathbf{E} + \mathbf{U} \times \mathbf{B}) \quad (11.125)$$

The left-hand side is the space part of a 4-vector. The corresponding time component equation is the rate of change of energy of the particle (6.110):

$$\frac{dp_0}{d\tau} = \frac{q}{c} \mathbf{U} \cdot \mathbf{E} \quad (11.126)$$

If the force and energy change equations are to be Lorentz covariant, the right-hand sides must form the components of a 4-vector. They involve products of three factors, the charge q , the 4-velocity, and the electromagnetic fields. If the transformation properties of two of the three factors are known and Lorentz covariance is demanded, then the transformation properties of the third factor can be established.

Electric charge is absolutely conserved, as far as we know. Furthermore, the magnitudes of the charges of elementary particles (and therefore of any system of charges) are integral multiples of the charge of the proton. In the published

* See, for example, Section. 2.4c of A. Bohr and B. R. Mottelson, *Nuclear Structure*, Vol. 1, W. A. Benjamin, New York (1969).

literature,* it is experimentally established that the fractional difference between the magnitude of the electron's charge and the proton's charge is less than 10^{-19} , and unpublished results of King push this limit almost two orders of magnitude further.† The results of these experiments can be used to support the *invariance of electric charge* under Lorentz transformations or, more concretely, the independence of the observed charge of a particle on its speed. In King's experiments a search was made for a residual charge remaining in a container as hydrogen or helium gas is allowed to escape. No effect was observed and a limit of less than $10^{-19}e$ was established for the net charge per molecule for both H_2 and He. Since the electrons in He move at speeds twice as fast as in H_2 , the charge of the electron cannot depend significantly on its speed, at least for speeds of the order of $(0.01-0.02)c$. In the experiment of Fraser, Carlson, and Hughes an atomic beam apparatus was used in an attempt to observe electrostatic deflection of beams of "neutral" cesium and potassium atoms. Again, no effect was observed, and a limit of less than 3.5×10^{-19} was set on the fractional difference between the charges of the proton and electron. Cesium and potassium have $Z=55$ and 19, respectively. Thus the K -shell electrons in cesium at least move with speeds of order $0.4c$. The observed neutrality of the cesium atom at the level of 10^{-18} – 10^{-19} is strong evidence for the invariance of electric charge.‡

The *experimental* invariance of electric charge and the requirement of Lorentz covariance of the Lorentz force equation (11.125) and (11.126) determines the Lorentz transformation properties of the electromagnetic field. For example, the requirement from (11.126) that $\mathbf{U} \cdot \mathbf{E}$ be the time component of a 4-vector establishes that the components of \mathbf{E} are the time-space parts of a second rank tensor $F^{\alpha\beta}$, that is, $\mathbf{E} \cdot \mathbf{U} = F^{0\beta}U_\beta$. Although the explicit form of the field strength tensor $F^{\alpha\beta}$ can be found along these lines, we now proceed to examine the Maxwell equations themselves.

For simplicity, we consider the microscopic Maxwell equations, without \mathbf{D} and \mathbf{H} . We begin with the charge density $\rho(\mathbf{x}, t)$ and current density $\mathbf{J}(\mathbf{x}, t)$ and the continuity equation,

$$\frac{\partial \rho}{\partial t} + \nabla \cdot \mathbf{J} = 0 \quad (11.127)$$

* J. G. King, *Phys. Rev. Letters* **5**, 562 (1960); L. J. Fraser, E. R. Carlson, and V. W. Hughes, *Bull. Am. Phys. Soc.* **13**, 636 (1968).

† The present limits on the measured charge per molecule in units of the electronic charge for H_2 , He, and SF_6 are 1.8 ± 5.4 , -0.7 ± 4.7 , 0 ± 4.3 , respectively, all times 10^{-21} . Private communication from J. G. King.

‡ Mentioning only the electrons is somewhat misleading. The protons and neutrons inside nuclei move with speeds of the order $(0.2-0.3)c$. Thus the helium results of King already test the invariance of charge at appreciable speeds. Of course, if one is content with invariance at the level of 10^{-10} for $v/c \sim 10^{-3}$ the observed electrical neutrality of bulk matter when heated or cooled will suffice.

From the discussion at the end of Section 11.6 and especially (11.77) it is natural to postulate that ρ and \mathbf{J} together form a 4-vector J^α :

$$J^\alpha = (c\rho, \mathbf{J}) \quad (11.128)$$

Then the continuity equation (11.127) takes the obviously covariant form,

$$\partial_\alpha J^\alpha = 0 \quad (11.129)$$

where the covariant differential operator ∂_α is given by (11.76). That J^α is a legitimate 4-vector follows from the invariance of electric charge: The charge in a small volume element d^3x is ρd^3x . Since this is an experimental invariant, it is true that $\rho' d^3x' = \rho d^3x$. But the four-dimensional volume element $d^4x = dx_0 d^3x$ is a Lorentz invariant:

$$d^4x' = \frac{\partial(x'^0, x'^1, x'^2, x'^3)}{\partial(x^0, x^1, x^2, x^3)} d^4x = \det A d^4x = d^4x$$

The equality $\rho' d^3x' = \rho d^3x$ then implies that $c\rho$ transforms like x^0 , namely, the time component of the 4-vector (11.128).

In the Lorentz family of gauges the wave equations for the vector potential \mathbf{A} and the scalar potential Φ are

$$\left. \begin{aligned} \frac{1}{c^2} \frac{\partial^2 \mathbf{A}}{\partial t^2} - \nabla^2 \mathbf{A} &= \frac{4\pi}{c} \mathbf{J} \\ \frac{1}{c^2} \frac{\partial^2 \Phi}{\partial t^2} - \nabla^2 \Phi &= 4\pi\rho \end{aligned} \right\} \quad (11.130)$$

with the Lorentz condition,

$$\frac{1}{c} \frac{\partial \Phi}{\partial t} + \nabla \cdot \mathbf{A} = 0 \quad (11.131)$$

The differential operator form in (11.130) is the invariant four-dimensional Laplacian (11.78), while the right-hand sides are the components of a 4-vector. Obviously, Lorentz covariance requires that the potentials Φ and \mathbf{A} form a 4-vector potential,

$$A^\alpha = (\Phi, \mathbf{A}) \quad (11.132)$$

Then the wave equations and the Lorentz condition take on the manifestly covariant forms,

$$\left. \begin{aligned} \square A^\alpha &= \frac{4\pi}{c} J^\alpha \\ \partial_\alpha A^\alpha &= 0 \end{aligned} \right\} \quad (11.133)$$

and

The fields \mathbf{E} and \mathbf{B} are expressed in terms of the potentials as

$$\begin{aligned}\mathbf{E} &= -\frac{1}{c} \frac{\partial \mathbf{A}}{\partial t} - \nabla \Phi \\ \mathbf{B} &= \nabla \times \mathbf{A}\end{aligned}\quad (11.134)$$

The x components of \mathbf{E} and \mathbf{B} are explicitly

$$\begin{aligned}E_x &= -\frac{1}{c} \frac{\partial A_x}{\partial t} - \frac{\partial \Phi}{\partial x} = -(\partial^0 A^1 - \partial^1 A^0) \\ B_x &= \frac{\partial A_z}{\partial y} - \frac{\partial A_y}{\partial z} = -(\partial^2 A^3 - \partial^3 A^2)\end{aligned}\quad (11.135)$$

where the second forms follow from (11.132) and $\partial^\alpha = (\partial/\partial x_0, -\nabla)$. These equations imply that the electric and magnetic fields, six components in all, are the elements of a *second-rank, antisymmetric field-strength tensor*,

$$F^{\alpha\beta} = \partial^\alpha A^\beta - \partial^\beta A^\alpha \quad (11.136)$$

Explicitly, the field-strength tensor is, in matrix form,

$$F^{\alpha\beta} = \begin{pmatrix} 0 & -E_x & -E_y & -E_z \\ E_x & 0 & -B_z & B_y \\ E_y & B_z & 0 & -B_x \\ E_z & -B_y & B_x & 0 \end{pmatrix} \quad (11.137)$$

For reference, we record the field-strength tensor with two covariant indices,

$$F_{\alpha\beta} = g_{\alpha\gamma} F^{\gamma\delta} g_{\delta\beta} = \begin{pmatrix} 0 & E_x & E_y & E_z \\ -E_x & 0 & -B_z & B_y \\ -E_y & B_z & 0 & -B_x \\ -E_z & -B_y & B_x & 0 \end{pmatrix} \quad (11.138)$$

The elements of $F_{\alpha\beta}$ are obtained from $F^{\alpha\beta}$ by putting $\mathbf{E} \rightarrow -\mathbf{E}$. Another useful quantity is the *dual field-strength tensor* $\mathcal{F}^{\alpha\beta}$. We first define the totally antisymmetric fourth rank tensor $\epsilon^{\alpha\beta\gamma\delta}$:

$$\epsilon^{\alpha\beta\gamma\delta} = \begin{cases} +1 & \text{for } \alpha=0, \beta=1, \gamma=2, \delta=3, \text{ and} \\ & \text{any even permutation} \\ -1 & \text{for any odd permutation} \\ 0 & \text{if any two indices are equal} \end{cases} \quad (11.139)$$

Note that the nonvanishing elements all have one time and three (different) space indices and that $\epsilon_{\alpha\beta\gamma\delta} = -\epsilon^{\alpha\beta\gamma\delta}$. The tensor $\epsilon^{\alpha\beta\gamma\delta}$ is a *pseudotensor* under spatial inversions. This can be seen by contracting it with four different 4-vectors

and examining the space inversion properties of the resultant rotationally invariant quantity. The dual field-strength tensor is defined by

$$\mathcal{F}^{\alpha\beta} = \frac{1}{2}\epsilon^{\alpha\beta\gamma\delta}F_{\gamma\delta} = \begin{pmatrix} 0 & -B_x & -B_y & -B_z \\ B_x & 0 & E_z & -E_y \\ B_y & -E_z & 0 & E_x \\ B_z & E_y & -E_x & 0 \end{pmatrix} \quad (11.140)$$

The elements of the dual tensor $\mathcal{F}^{\alpha\beta}$ are obtained from $F^{\alpha\beta}$ by putting $\mathbf{E} \rightarrow \mathbf{B}$ and $\mathbf{B} \rightarrow -\mathbf{E}$ in (11.137). This is a special case of the duality transformation (6.151).

To complete the demonstration of the covariance of electrodynamics we must write the Maxwell equations themselves in an explicitly covariant form. The inhomogeneous equations are

$$\begin{aligned} \nabla \cdot \mathbf{E} &= 4\pi\rho \\ \nabla \times \mathbf{B} - \frac{1}{c} \frac{\partial \mathbf{E}}{\partial t} &= \frac{4\pi}{c} \mathbf{J} \end{aligned}$$

In terms of $F^{\alpha\beta}$ and the 4-current J^α these take on the covariant form,

$$\partial_\alpha F^{\alpha\beta} = \frac{4\pi}{c} J^\beta \quad (11.141)$$

Similarly, the homogeneous Maxwell equations,

$$\nabla \cdot \mathbf{B} = 0, \quad \nabla \times \mathbf{E} + \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t} = 0$$

can be written in terms of the dual field-strength tensor as

$$\partial_\alpha \mathcal{F}^{\alpha\beta} = 0 \quad (11.142)$$

In terms of $F^{\alpha\beta}$, rather than $\mathcal{F}^{\alpha\beta}$, these homogeneous equations are the four equations,

$$\partial^\alpha F^{\beta\gamma} + \partial^\beta F^{\gamma\alpha} + \partial^\gamma F^{\alpha\beta} = 0 \quad (11.143)$$

where α, β, γ are any three of the integers 0, 1, 2, 3.

With the definitions of J^α (11.128), A^α (11.132), and $F^{\alpha\beta}$ (11.136), together with the wave equations (11.133) or the Maxwell equations (11.141) and (11.142), the covariance of the equations of electromagnetism is established. To complete the discussion we put the Lorentz force and rate of change of energy equations (11.125) and (11.126) in manifestly covariant form,

$$\frac{dp^\alpha}{d\tau} = m \frac{dU^\alpha}{d\tau} = \frac{q}{c} F^{\alpha\beta} U_\beta \quad (11.144)$$

The covariant description of the conservation laws of a combined system of electromagnetic fields and charged particles and a covariant solution for the fields of a moving charge are deferred to Chapter 12 where a Lagrangian formulation is presented.

For the macroscopic Maxwell equations it is necessary to distinguish two field strength tensors, $F^{\alpha\beta} = (\mathbf{E}, \mathbf{B})$ and $G^{\alpha\beta} = (\mathbf{D}, \mathbf{H})$, where $F^{\alpha\beta}$ is given by (11.137) and $G^{\alpha\beta}$ is obtained from (11.137) by substituting $\mathbf{E} \rightarrow \mathbf{D}$ and $\mathbf{B} \rightarrow \mathbf{H}$. The covariant form of the Maxwell equations is then

$$\partial_\alpha G^{\alpha\beta} = \frac{4\pi}{c} J^\beta, \quad \partial_\alpha \mathcal{F}^{\alpha\beta} = 0 \quad (11.145)$$

It is clear that with the fields (\mathbf{E}, \mathbf{B}) and (\mathbf{D}, \mathbf{H}) transforming as antisymmetric second rank tensors the polarization \mathbf{P} and the negative magnetization $-\mathbf{M}$ form a similar second rank tensor. With these quantities given meaning as macroscopic averages of atomic properties *in the rest frame* of the medium, the electrodynamics of macroscopic matter in motion is specified. This is the basis of the electrodynamics of Minkowski and others. For further information on this rather large and important subject the reader can consult the literature cited at the end of the chapter.

11.10 Transformation of Electromagnetic Fields

Since the fields \mathbf{E} and \mathbf{B} are the elements of a second rank tensor $F^{\alpha\beta}$, their values in one inertial frame K' can be expressed in terms of the values in another inertial frame K according to

$$F'^{\alpha\beta} = \frac{\partial x'^\alpha}{\partial x^\gamma} \frac{\partial x'^\beta}{\partial x^\delta} F^{\gamma\delta} \quad (11.146)$$

In the matrix notation of Section 11.7 this can be written

$$F' = A F \tilde{A} \quad (11.147)$$

where F and F' are 4×4 matrices (11.137) and A is the Lorentz transformation matrix of (11.93). For the specific Lorentz transformation (11.95), corresponding to a boost along the x_1 axis with speed $c\beta$ from the unprimed frame to the primed frame, the explicit equations of transformation are

$$\begin{aligned} E'_1 &= E_1 & B'_1 &= B_1 \\ E'_2 &= \gamma(E_2 - \beta B_3) & B'_2 &= \gamma(B_2 + \beta E_3) \\ E'_3 &= \gamma(E_3 + \beta B_2) & B'_3 &= \gamma(B_3 - \beta E_2) \end{aligned} \quad (11.148)$$

Here and below the subscripts 1, 2, 3 indicate ordinary Cartesian spatial components and are not covariant indices. The inverse of (11.148) is found, as usual, by interchanging primed and unprimed quantities and putting $\beta \rightarrow -\beta$. For a general Lorentz transformation from K to a system K' moving with velocity \mathbf{v} relative to K , the transformation of the fields can be written

$$\left. \begin{aligned} \mathbf{E}' &= \gamma(\mathbf{E} + \boldsymbol{\beta} \times \mathbf{B}) - \frac{\gamma^2}{\gamma + 1} \boldsymbol{\beta}(\boldsymbol{\beta} \cdot \mathbf{E}) \\ \mathbf{B}' &= \gamma(\mathbf{B} - \boldsymbol{\beta} \times \mathbf{E}) - \frac{\gamma^2}{\gamma + 1} \boldsymbol{\beta}(\boldsymbol{\beta} \cdot \mathbf{B}) \end{aligned} \right\} \quad (11.149)$$

Fig. 11.8 Particle of charge q moving at constant velocity \mathbf{v} passes an observation point P at impact parameter b .

These are the analogues for the fields of (11.19) for the coordinates. Transformation (11.149) shows that \mathbf{E} and \mathbf{B} have no independent existence. A purely electric or magnetic field in one coordinate system will appear as a mixture of electric and magnetic fields in another coordinate frame. Of course certain restrictions apply (see Problem 11.12) so that, for example, a purely electrostatic field in one coordinate system cannot be transformed into a purely magnetostatic field in another. But the fields are completely interrelated, and one should properly speak of the electromagnetic field $F^{\alpha\beta}$, rather than \mathbf{E} or \mathbf{B} separately.

As an example of the transformation of the electromagnetic fields, we consider the fields seen by an observer in the system K when a point charge q moves by in a straightline path with a velocity \mathbf{v} . The charge is at rest in the system K' , and the transformation of the fields is given by the inverse of (11.148) or (11.149). We suppose that the charge moves in the positive x_1 direction and that its closest distance of approach to the observer is b . Figure 11.8 shows a suitably chosen set of axes. The observer is at the point P . At $t = t' = 0$ the origins of the two coordinate systems coincide and the charge q is at its closest distance to the observer. In the frame K' the observer's point P , where the fields are to be evaluated, has coordinates $x_1' = -vt'$, $x_2' = b$, $x_3' = 0$, and is a distance $r' = \sqrt{b^2 + (vt')^2}$ away from q . We will need to express r' in terms of the coordinates in K . The only coordinate needing transformation is the time $t' = \gamma[t - (v/c^2)x_1] = \gamma t$, since $x_1 = 0$ for the point P in the frame K . In the rest frame K' of the charge the electric and magnetic fields at the observation point are

$$\left. \begin{aligned} E_1' &= -\frac{qv t'}{r'^3}, & E_2' &= \frac{qb}{r'^3}, & E_3' &= 0 \\ B_1' &= 0, & B_2' &= 0, & B_3' &= 0 \end{aligned} \right\} \quad (11.150)$$

In terms of the coordinates of K the nonvanishing field components are

$$E_1' = -\frac{q\gamma vt}{(b^2 + \gamma^2 v^2 t^2)^{3/2}}, \quad E_2' = \frac{qb}{(b^2 + \gamma^2 v^2 t^2)^{3/2}} \quad (11.151)$$

Then, using the inverse of (11.148), we find the transformed fields in the system K :

$$\left. \begin{aligned} E_1 &= E'_1 = -\frac{q\gamma vt}{(b^2 + \gamma^2 v^2 t^2)^{3/2}} \\ E_2 &= \gamma E'_2 = \frac{\gamma qb}{(b^2 + \gamma^2 v^2 t^2)^{3/2}} \\ B_3 &= \gamma\beta E'_2 = \beta E_2 \end{aligned} \right\} \quad (11.152)$$

with the other components vanishing.

Fields (11.152) exhibit interesting behavior when the velocity of the charge approaches that of light. First of all there is observed a magnetic induction in the x_3 direction. This magnetic field becomes almost equal to the transverse electric field E_2 as $\beta \rightarrow 1$. Even at nonrelativistic velocities where $\gamma \approx 1$, this magnetic induction is equivalent to

$$\mathbf{B} \approx \frac{q}{c} \frac{\mathbf{v} \times \mathbf{r}}{r^3}$$

which is just the Ampère-Biot-Savart expression for the magnetic field of a moving charge. This can evidently be obtained directly from the inverse of (11.149). At high speeds when $\gamma \gg 1$ we see that the peak transverse electric field E_2 ($t=0$) becomes equal to γ times its nonrelativistic value. In the same limit, however, the duration of appreciable field strengths at the point P is decreased. A measure of the time interval over which the fields are appreciable is evidently

$$\Delta t \approx \frac{b}{\gamma v} \quad (11.153)$$

As γ increases, the peak fields increase in proportion, but their duration goes in inverse proportion. The time integral of the fields times v is independent of velocity. Figure 11.9a shows this behavior of the transverse electric and magnetic fields and the longitudinal electric field. For $\beta \rightarrow 1$ the observer at P sees nearly equal transverse and mutually perpendicular electric and magnetic fields. These are indistinguishable from the fields of a pulse of plane polarized radiation propagating in the x_1 direction. The extra longitudinal electric field varies rapidly from positive to negative and has zero time integral. If the observer's detecting apparatus has any significant inertia, it will not respond to this longitudinal field. Consequently for practical purposes he will see only the transverse fields. This equivalence of the fields of a relativistic charged particle and those of a pulse of electromagnetic radiation will be exploited in Chapter 15.

The fields (11.152) and the curves of Fig. 11.9a emphasize the time dependence of the fields at a fixed observation point. An alternative description can be given in terms of the spatial variation of the fields relative to the

Fig. 11.9 Fields of a uniformly moving charged particle. (a) Fields at the observation point P in Fig. 11.8 as a function of time. (b) Lines of electric force for a particle at rest and in motion ($\gamma=3$).

instantaneous *present* position of the charge in the laboratory. From (11.152) we see that $E_1/E_2 = -vt/b$. Reference to Fig. 11.8 shows that the electric field is thus directed along \mathbf{n} , a unit radial vector from the charge's present position to the observation point, just as for a static Coulomb field. By expressing the denominator in (11.152) in terms of r , the radial distance from the present position to the observer, and the angle $\psi = \cos^{-1}(\mathbf{n} \cdot \hat{\mathbf{v}})$ shown in Fig. 11.8, we obtain the electric field in terms of the charge's present position:

$$\mathbf{E} = \frac{q\mathbf{r}}{r^3 \gamma^2 (1 - \beta^2 \sin^2 \psi)^{3/2}} \quad (11.154)$$

The field is radial, but the lines of force are isotropically distributed only for

$\beta = 0$. Along the direction of motion ($\psi = 0, \pi$), the field strength is down by a factor of γ^{-2} relative to isotropy, while in the transverse directions ($\psi = \pi/2$) it is larger by a factor of γ . This whiskbroom pattern of lines of force, shown in Fig. 11.9b, is the spatial “snapshot” equivalent of the temporal behavior sketched in part (a) of that figure. The compression of the lines of force in the transverse direction can be viewed as a consequence of the FitzGerald-Lorentz contraction.

11.11 Relativistic Equation of Motion for Spin in Uniform or Slowly Varying External Fields

The effects of a particle’s motion on the precession of its spin have already been discussed in Section 11.8 on Thomas precession. Here we exploit the ideas of Lorentz covariance to give an alternative, more elegant discussion leading to what is known as the BMT equation of motion for the spin.* With the magnetic moment given by (11.100), the rest frame equation of motion for the spin, (11.101), is

$$\frac{ds}{dt'} = \frac{ge}{2mc} \mathbf{s} \times \mathbf{B}' \quad (11.155)$$

where primes denote quantities defined in the rest frame and \mathbf{s} is the spin in that frame. This equation applies to a particle of mass m , charge e , spin \mathbf{s} and a magnetic dipole moment with Landé g factor of g . It is a classical equation, but is the same as the quantum-mechanical Heisenberg equation of motion for the spin operator or, equivalently, the equation of motion for the polarization vector of the system.

(a) Covariant Equation of Motion

To obtain a relativistic generalization of (11.155) it is first necessary to generalize the spin \mathbf{s} from a 3-vector in the particle’s rest frame. There are two avenues open. One is to recall from the end of Section 11.9 that \mathbf{P} and $-\mathbf{M}$ form an antisymmetric second rank tensor. Thus $\boldsymbol{\mu}$ and hence \mathbf{s} can be generalized to a second rank tensor $S^{\alpha\beta}$. A simpler alternative is to define an axial 4-vector S^α in such a manner that it has only three independent components and reduces to the spin \mathbf{s} in the particle’s rest frame.† If S^α denotes the components of the spin 4-vector in the inertial frame K , the time-component in the rest frame K' is,

* Named, not after one of the New York City subway lines, but for V. Bargmann, L. Michel, and V. L. Telegdi, *Phys. Rev. Letters* **2**, 435 (1959). The equation actually has much earlier origins; Thomas published an equivalent in 1927 (*op. cit.*); Frenkel discussed similar equations contemporaneously; Kramers considered the $g=2$ equation in the 1930s.

† The spin 4-vector S^α is the dual of the tensor $S^{\alpha\beta}$ in the sense that $S^\alpha = (1/2c)\epsilon^{\alpha\beta\gamma\delta}U_\beta S_{\gamma\delta}$, where U^α is the particle’s 4-velocity.

according to (11.22),

$$S'^0 = \gamma(S^0 - \boldsymbol{\beta} \cdot \mathbf{S}) = \frac{1}{c} U_\alpha S^\alpha$$

where U^α is the particle's 4-velocity. We see that the vanishing of the time-component in the rest frame is imposed by the covariant constraint,

$$U_\alpha S^\alpha = 0 \quad (11.156)$$

In an inertial frame where the particle's velocity is $c\boldsymbol{\beta}$ the time component of spin is therefore not independent, but is

$$S_0 = \boldsymbol{\beta} \cdot \mathbf{S} \quad (11.157)$$

It is useful to display the explicit connection between S^α and the rest-frame spin \mathbf{s} . Use of (11.19) or (11.22) and (11.157) yields

$$\mathbf{s} = \mathbf{S} - \frac{\gamma}{\gamma+1} (\boldsymbol{\beta} \cdot \mathbf{S}) \boldsymbol{\beta} \quad (11.158)$$

and the inverse expressions

$$\left. \begin{aligned} \mathbf{S} &= \mathbf{s} + \frac{\gamma^2}{\gamma+1} (\boldsymbol{\beta} \cdot \mathbf{s}) \boldsymbol{\beta} \\ S_0 &= \gamma \boldsymbol{\beta} \cdot \mathbf{s} \end{aligned} \right\} \quad (11.159)$$

Specification of the rest-frame 3-vector spin \mathbf{s} determines the components of the 4-vector spin S^α in any inertial frame.

The obvious generalization of the left-hand side of (11.155) is $dS^\alpha/d\tau$, where τ is the particle's proper time. The right-hand side must therefore be expressible as a 4-vector. We assume that the equation is linear in the spin S^α and the external fields $F^{\alpha\beta}$. It can also involve U^α and $dU^\alpha/d\tau$, the latter being linear in $F^{\alpha\beta}$ itself. Higher time derivatives are assumed absent. And of course the equation must reduce to (11.155) in the rest frame. With the building blocks S^α , $F^{\alpha\beta}$, U^α , $dU^\alpha/d\tau$ and the requirement of linearity in S^α and $F^{\alpha\beta}$, we can construct the 4-vectors,

$$F^{\alpha\beta} S_\beta, \quad (S_\lambda F^{\lambda\mu} U_\mu) U^\alpha, \quad \left(S_\beta \frac{dU^\beta}{d\tau} \right) U^\alpha$$

Other possibilities, such as $F^{\alpha\beta} U_\beta (S_\lambda U^\lambda)$, $(U_\lambda F^{\lambda\mu} U_\mu) S^\alpha$, $(S_\lambda F^{\lambda\mu} U_\mu) dU^\alpha/d\tau$, etc. either vanish, are higher order in $F^{\alpha\beta}$, or reduce to multiples of the above three. The equation of motion must therefore be of the form,

$$\frac{dS^\alpha}{d\tau} = A_1 F^{\alpha\beta} S_\beta + \frac{A_2}{c^2} (S_\lambda F^{\lambda\mu} U_\mu) U^\alpha + \frac{A_3}{c^2} \left(S_\beta \frac{dU^\beta}{d\tau} \right) U^\alpha \quad (11.160)$$

where A_1 , A_2 , A_3 are constants. The constraint equation (11.156) must hold at

all times. This requires

$$\frac{d}{d\tau}(U_\alpha S^\alpha) = S^\alpha \frac{dU_\alpha}{d\tau} + U_\alpha \frac{dS^\alpha}{d\tau} = 0$$

and hence

$$(A_1 - A_2)U_\alpha F^{\alpha\beta}S_\beta + (1 + A_3)S_\beta \frac{dU^\beta}{d\tau} = 0 \quad (11.161)$$

If nonelectromagnetic or field gradient forces are allowed, at least in principle, it is necessary that $A_1 = A_2$ and $A_3 = -1$. Reduction to the rest frame and comparison with (11.155) gives $A_1 = ge/2mc$. Thus (11.160) becomes

$$\frac{dS^\alpha}{d\tau} = \frac{ge}{2mc} \left[F^{\alpha\beta}S_\beta + \frac{1}{c^2} U^\alpha (S_\lambda F^{\lambda\mu} U_\mu) \right] - \frac{1}{c^2} U^\alpha \left(S_\lambda \frac{dU^\lambda}{d\tau} \right) \quad (11.162)$$

If the electromagnetic fields are uniform in space, or if gradient force terms like $\nabla(\boldsymbol{\mu} \cdot \mathbf{B})$, (5.69), can be neglected, and there are no other appreciable forces on the particle, its translational motion is described by (11.144):

$$\frac{dU^\alpha}{d\tau} = \frac{e}{mc} F^{\alpha\beta} U_\beta \quad (11.163)$$

Then (11.162) becomes the *BMT equation*:

$$\frac{dS^\alpha}{d\tau} = \frac{e}{mc} \left[\frac{g}{2} F^{\alpha\beta} S_\beta + \frac{1}{c^2} \left(\frac{g}{2} - 1 \right) U^\alpha (S_\lambda F^{\lambda\mu} U_\mu) \right] \quad (11.164)$$

(b) *Connection to the Thomas Precession*

The covariant equation (11.162), or its special case (11.164), contain the Thomas precession of the spin. It occurs in the final term in (11.162), the term that was specified by the requirement (11.156) that the spin 4-vector be orthogonal to the 4-velocity. To exhibit the Thomas precession explicitly, we consider the equation of motion for the rest-frame spin \mathbf{s} . Using the result

$$S_\lambda \frac{dU^\lambda}{d\tau} = -\gamma \mathbf{S} \cdot \frac{d\mathbf{v}}{d\tau} \quad (11.165)$$

and (11.158) for \mathbf{s} in terms of \mathbf{S} , we find that the equations,

$$\frac{d\mathbf{S}}{d\tau} = \mathbf{F} + \gamma^2 \boldsymbol{\beta} \left(\mathbf{S} \cdot \frac{d\boldsymbol{\beta}}{d\tau} \right)$$

and

$$\frac{dS_0}{d\tau} = F_0 + \gamma^2 \left(\mathbf{S} \cdot \frac{d\boldsymbol{\beta}}{d\tau} \right)$$

can be combined to give, after some simplification,

$$\frac{d\mathbf{s}}{d\tau} = \mathbf{F} - \frac{\gamma\boldsymbol{\beta}}{\gamma+1} F_0 + \frac{\gamma^2}{\gamma+1} \left[\mathbf{s} \times \left(\boldsymbol{\beta} \times \frac{d\boldsymbol{\beta}}{d\tau} \right) \right] \quad (11.166)$$

In these equations (F_0, \mathbf{F}) stand for the time and space components of the terms with coefficient ($ge/2mc$) in (11.162). Since (F_0, \mathbf{F}) form a 4-vector, with $F_0 = \boldsymbol{\beta} \cdot \mathbf{F}$, the first two terms in (11.166) can be recognized as the torque \mathbf{F}' evaluated in the rest frame. Dividing both sides by γ and using the definition (11.119) for the Thomas precession frequency, we find that (11.166) becomes

$$\frac{d\mathbf{s}}{dt} = \frac{1}{\gamma} \mathbf{F}' + \boldsymbol{\omega}_T \times \mathbf{s} \quad (11.167)$$

Since \mathbf{F}' is given by the right-hand side of (11.155), this is just (11.107) of Section 11.8.

For motion in electromagnetic fields where (11.163) holds,

$$\frac{d\boldsymbol{\beta}}{dt} = \frac{e}{\gamma mc} [\mathbf{E} + \boldsymbol{\beta} \times \mathbf{B} - \boldsymbol{\beta}(\boldsymbol{\beta} \cdot \mathbf{E})] \quad (11.168)$$

We also have, from the transformation properties (11.149) of \mathbf{B} ,

$$\frac{1}{\gamma} \mathbf{F}' = \frac{ge}{2mc} \mathbf{s} \times \left[\mathbf{B} - \frac{\gamma}{\gamma+1} (\boldsymbol{\beta} \cdot \mathbf{B}) \boldsymbol{\beta} - \boldsymbol{\beta} \times \mathbf{E} \right] \quad (11.169)$$

When these expressions are inserted into (11.167), it becomes

$$\frac{d\mathbf{s}}{dt} = \frac{e}{mc} \mathbf{s} \times \left[\left(\frac{g}{2} - 1 + \frac{1}{\gamma} \right) \mathbf{B} - \left(\frac{g}{2} - 1 \right) \frac{\gamma}{\gamma+1} (\boldsymbol{\beta} \cdot \mathbf{B}) \boldsymbol{\beta} - \left(\frac{g}{2} - \frac{\gamma}{\gamma+1} \right) \boldsymbol{\beta} \times \mathbf{E} \right] \quad (11.170)$$

This form of the equation of motion of the spin vector is *Thomas's equation* (4.121) (*op. cit.*).

(c) Rate of Change of Longitudinal Polarization

As an example of the use of (11.170) we consider the rate of change of the component of spin \mathbf{s} parallel to the velocity. This is the longitudinal polarization or net helicity of the particle. If $\hat{\boldsymbol{\beta}}$ is a unit vector in the direction of $\boldsymbol{\beta}$, the longitudinal polarization is $\hat{\boldsymbol{\beta}} \cdot \mathbf{s}$. It changes in time because \mathbf{s} changes and also $\boldsymbol{\beta}$ changes. Explicitly, we have

$$\frac{d}{dt} (\hat{\boldsymbol{\beta}} \cdot \mathbf{s}) = \hat{\boldsymbol{\beta}} \cdot \frac{d\mathbf{s}}{dt} + \frac{1}{\beta} [\mathbf{s} - (\hat{\boldsymbol{\beta}} \cdot \mathbf{s}) \hat{\boldsymbol{\beta}}] \cdot \frac{d\boldsymbol{\beta}}{dt}$$

Using (11.168) and (11.170), this can be written, after some algebra, as

$$\frac{d}{dt} (\hat{\boldsymbol{\beta}} \cdot \mathbf{s}) = -\frac{e}{mc} \mathbf{s}_\perp \cdot \left[\left(\frac{g}{2} - 1 \right) \hat{\boldsymbol{\beta}} \times \mathbf{B} + \left(\frac{g\beta}{2} - \frac{1}{\beta} \right) \mathbf{E} \right] \quad (11.171)$$

where \mathbf{s}_\perp is the component of \mathbf{s} perpendicular to the velocity.

Equation (11.171) demonstrates a remarkable property of a particle with $g=2$. In a purely magnetic field, the spin precesses in such a manner that the longitudinal polarization remains constant, whatever the motion of the particle. If the particle is relativistic ($\beta \rightarrow 1$), even the presence of an electric field causes

the longitudinal polarization to change only very slowly, at a rate proportional to γ^{-2} times the electric field component perpendicular to \mathbf{v} .

The electron and the muon have g -factors differing from the Dirac value of 2 by radiative corrections of order $\alpha/\pi = 0.00232$. Because $(g-2)$ is so small, the longitudinal polarization of a beam of electrons or muons orbiting in a magnetic field changes relatively slowly. This phenomenon permits very precise measurements of the quantity $a \equiv (g-2)/2$, called the anomaly or the anomalous magnetic moment. The values of a provide accurate tests of the validity of quantum electrodynamics. For muons, 100 per cent longitudinally polarized at birth, the change in polarization is detected by means of the characteristically asymmetric angular distribution of the decay electron from the muon relative to the direction of muon polarization. For electrons from beta decay the initial longitudinal polarization is $\pm\beta$. Its change with time is detected by changes in the asymmetry of Mott scattering (e^-) or the angular distribution of the annihilation photons from positronium formed in an intense magnetic field (e^+). The precision attainable by these techniques is indicated by the most recent data:*

$$a(e^-) = (115,965.77 \pm 0.35) \times 10^{-8}$$

$$a(e^+) = (116,030 \pm 120) \times 10^{-8}$$

$$a(\mu^\pm) = (116,616 \pm 31) \times 10^{-8}$$

These results are in good agreement with the predictions of quantum electrodynamics, as discussed in detail in the review by Bailey and Picasso.

Further elaboration of spin precession is left to the problems at the end of Chapter 12.

11.12 Note on Notation and Units in Relativistic Kinematics

In dealing with Lorentz transformations and relativistic kinematics, it is convenient to adopt a consistent, simple notation and set of units. We have seen that various powers of the velocity of light c appear in the formulas of special relativity. These tend to make the formulas cumbersome, although their presence facilitates extracting nonrelativistic limits (by letting $c \rightarrow \infty$). In doing relativistic kinematics, it is customary to suppress all factors of c by suitable choice of units. We adopt the convention that all momenta, energies, and masses are measured in energy units, while velocities are measured in units of the

* e^- : J. C. Wesley and A. Rich, *Phys. Rev.* **A4**, 1341 (1971).

e^+ : J. R. Gilleland and A. Rich, *Phys. Rev.* **A5**, 38 (1972).

μ^\pm : J. Bailey et al., *Phys. Letters* **28B**, 287 (1968).

See also the review by J. Bailey and E. Picasso, *Progress in Nuclear Physics*, Vol. 12, Part 1, eds. D. M. Brink and J. H. Mulvey Pergamon, Oxford, (1970), pp. 43-75.

velocity of light. In particle kinematics the symbols,

$$\left. \begin{matrix} p \\ E \\ m \\ v \end{matrix} \right\} \quad \text{stand for} \quad \left\{ \begin{matrix} cp \\ E \\ mc^2 \\ \frac{v}{c} \end{matrix} \right.$$

Thus the connection between momentum and total energy is written as $E^2 = p^2 + m^2$, a particle's velocity is $\mathbf{v} = \mathbf{p}/E$, and so on. As energy units, the eV (electron volt), the MeV (million electron volt), and the GeV (10^9 eV) are convenient. One electron volt is the energy gained by a particle with electronic charge when it falls through a potential difference of one volt ($1 \text{ eV} = 1.602 \times 10^{-12} \text{ ergs} = 1.602 \times 10^{-19} \text{ joules}$).

In addition to eliminating powers of c , it is customary to denote scalar products of 4-vectors by a centered dot between italicized symbols, with scalar products of 3-vectors denoted by a dot between boldface symbols, as usual. Thus we have

$$a \cdot b \equiv a_\alpha b^\alpha = a_0 b_0 - \mathbf{a} \cdot \mathbf{b}$$

Four-vectors may be written with or without an index. Thus conservation of energy and momentum may appear as

$$\begin{aligned} P &= p + q \\ \text{or} \quad P^\alpha &= p^\alpha + q^\alpha \end{aligned}$$

REFERENCES AND SUGGESTED READING

The theory of relativity has an extensive literature all its own. Perhaps the most lucid, though concise, presentation of special and general relativity is the famous 1921 encyclopedia article (brought up to date in 1956) by

Pauli.

Another authoritative book is

Møller.

Among the older textbooks on special relativity at the graduate level are

Aharoni

Bergmann, Chapters I-IX.

and, more recently,

Anderson, Chapters 6 and 7,

Barut, Chapters 1 and 2,

Schwartz,

Tonnellat, Part II.

The mathematics (group theory and tensor analysis) of space-time is covered from a physicist's point of view in

Anderson, Chapters 1-5,

Bergmann, Chapter V,

Schwartz, Chapter 5.

The flavor of the original theoretical developments can be obtained by consulting the collected papers of

Einstein, Lorentz, Minkowski, and Weyl,
and in the collection of reprints of
Kilmister.

A very individualistic discussion of special relativity, with extensive references and perceptive commentary, can be found in the two books by
Arzeliès.

The main experiments are summarized in

Møller, Chapters 1 and 12,
Condon and Odishaw, Part 6, Chapter 8 by E. L. Hill.

The barely mentioned topic of the electrodynamics of moving media is treated by
Cullwick,
Møller, pp. 209 ff,
Pauli, pp. 99 ff,
Penfield and Haus.

Cullwick discusses many practical situations. Be forewarned, however, about his Chapter 5 by reading his preface to the second edition.

Relativistic kinematics has been relegated to the problems. Useful references in this area are

Baldin, Gol'danskii and Rozenthal,
Hagedorn,
Sard, Chapter 4.

Another neglected subject is the appearance of rapidly moving objects. This fascinating topic illustrates how careful one must be with concepts such as the FitzGerald-Lorentz contraction. Some pertinent papers are

R. Penrose, *Proc. Camb. Phil. Soc.* **55**, 137 (1959),
J. Terrell, *Phys. Rev.* **116**, 1041 (1959),
V. F. Weisskopf, *Phys. Today* **13**, No. 9, 24 (1960),
M. L. Boas, *Am. J. Phys.* **29**, 283 (1961),
G. D. Scott and H. J. Van Driel, *Am. J. Phys.* **38**, 971 (1970).

For the reader who wishes a more elementary or leisurely introduction to special relativity, there are a host of undergraduate texts, among them

Bohm,
Feynman, Vol. 1, Chapters 15, 16, 17,
French,
Kacser,
Rosser,
Sard,
Smith,
Taylor and Wheeler.

Sard's book is specially recommended. It is at an intermediate level and has a thorough discussion of Thomas precession and the motion of spin. Hagedorn also discusses the BMT equation in detail.

Further references on specific topics can be found in the AAPT Resource Letter on Special Relativity SRT-1, *Am. J. Phys.* **30**, 462 (1962).

PROBLEMS

11.1 A possible clock is shown in the figure. It consists of a flashtube F and a photocell P shielded so that each views only the mirror M , located a distance d away, and

mounted rigidly with respect to the flashtube-photocell assembly. The electronic innards of the box are such that, when the photocell responds to a light flash from the mirror, the flashtube is triggered with a negligible delay and emits a short flash towards the mirror. The clock thus "ticks" once every $(2d/c)$ seconds when at rest.

Problem 11.1

(a) Suppose that the clock moves with a uniform velocity v , perpendicular to the line from PF to M , relative to an observer. Using the second postulate of relativity, show by explicit geometrical or algebraic construction that the observer sees the relativistic time dilatation as the clock moves by.

(b) Suppose that the clock moves with a velocity v parallel to the line from PF to M . Verify that here, too, the clock is observed to tick more slowly, by the same time dilatation factor.

11.2 Show explicitly that two successive Lorentz transformations in the same direction are equivalent to a single Lorentz transformation with a velocity

$$v = \frac{v_1 + v_2}{1 + (v_1 v_2 / c^2)}$$

This is an alternative way to derive the parallel-velocity addition law.

11.3 A coordinate system K' moves with a velocity \mathbf{v} relative to another system K . In K' a particle has a velocity \mathbf{u}' and an acceleration \mathbf{a}' . Find the Lorentz transformation law for accelerations, and show that in the system K the components of acceleration parallel and perpendicular to \mathbf{v} are

$$\mathbf{a}_{\parallel} = \frac{\left(1 - \frac{v^2}{c^2}\right)^{3/2}}{\left(1 + \frac{\mathbf{v} \cdot \mathbf{u}'}{c^2}\right)^3} \mathbf{a}'_{\parallel}$$

$$\mathbf{a}_{\perp} = \frac{\left(1 - \frac{v^2}{c^2}\right)}{\left(1 + \frac{\mathbf{v} \cdot \mathbf{u}'}{c^2}\right)^3} \left(\mathbf{a}'_{\perp} + \frac{\mathbf{v}}{c^2} \times (\mathbf{a}' \times \mathbf{u}') \right)$$

11.4 Assume that a rocket ship leaves the earth in the year 2000. One of a set of twins born in 1980 remains on earth; the other rides in the rocket. The rocket ship is so constructed that it has an acceleration g in its own rest frame (this makes the occupants feel at home). It accelerates in a straight-line path for 5 years (by its own clocks), decelerates at the same rate for 5 more years, turns around, accelerates for 5 years, decelerates for 5 years, and lands on earth. The twin in the rocket is 40 years old.

(a) What year is it on earth?

(b) How far away from the earth did the rocket ship travel?

11.5 In the reference frame K two very evenly matched sprinters are lined up a distance d apart on the y axis for a race parallel to the x axis. Two starters, one beside each man, will fire their starting pistols at slightly different times, giving a handicap to the better of the two runners. The time difference in K is T .

(a) For what range of time differences will there be a reference frame K' in which there is no handicap, and for what range of time differences is there a frame K' in which there is a true (not apparent) handicap?

(b) Determine explicitly the Lorentz transformation to the frame K' appropriate for each of the two possibilities in (a), finding the velocity of K' relative to K and the space-time positions of each sprinter in K' .

11.6 (a) Use the relativistic velocity addition law and the invariance of phase to discuss the Fizeau experiments on the velocity of propagation of light in moving liquids. Show that for liquid flow at a speed v parallel or antiparallel to the path of the light the speed of the light, as observed in the laboratory, is given to first order in v by

$$u = \frac{c}{n(\omega)} \pm v \left(1 - \frac{1}{n^2} + \frac{\omega}{n} \frac{dn(\omega)}{d\omega} \right)$$

where ω is the frequency of the light in the laboratory (in the liquid and outside it), $n(\omega)$ is the index of refraction of the liquid. Because of the extinction theorem, it is assumed that the light travels with speed $u' = c/n(\omega')$ relative to the moving liquid.

(b) Consult the paper of W. M. Macek, J. R. Schneider, and R. M. Salamon, *J. Appl. Phys.* **35**, 2556 (1964) and discuss the status of the Fizeau experiments.

11.7 An infinitesimal Lorentz transformation and its inverse can be written as

$$x'^{\alpha} = (g^{\alpha\beta} + \epsilon^{\alpha\beta})x_{\beta}$$

$$x^{\alpha} = (g^{\alpha\beta} + \epsilon'^{\alpha\beta})x'_{\beta}$$

where $\epsilon^{\alpha\beta}$ and $\epsilon'^{\alpha\beta}$ are infinitesimal.

(a) Show from the definition of the inverse that $\epsilon'^{\alpha\beta} = -\epsilon^{\alpha\beta}$.

(b) Show from the preservation of the norm that $\epsilon^{\alpha\beta} = -\epsilon^{\beta\alpha}$.

(c) By writing the transformation in terms of contravariant components on both sides of the equation, show that $\epsilon^{\alpha\beta}$ is equivalent to the matrix L (11.93).

11.8 (a) For the Lorentz boost and rotation matrices \mathbf{K} and \mathbf{S} show that

$$(\boldsymbol{\epsilon} \cdot \mathbf{S})^3 = -\boldsymbol{\epsilon} \cdot \mathbf{S}$$

$$(\boldsymbol{\epsilon}' \cdot \mathbf{K})^3 = \boldsymbol{\epsilon}' \cdot \mathbf{K}$$

where $\boldsymbol{\epsilon}$ and $\boldsymbol{\epsilon}'$ are any real unit 3-vectors.

(b) Use the results of (a) to show that

$$e^{-i\hat{\mathbf{p}} \cdot \mathbf{K}} = I - \hat{\mathbf{p}} \cdot \mathbf{K} \sinh \zeta + (\hat{\mathbf{p}} \cdot \mathbf{K})^2 [\cosh \zeta - 1]$$

11.9 Two Lorentz transformations differ by an infinitesimal amount. In the notation of Section 11.7 they are represented by $A_1 = e^L$, $A_2 = e^{L+\delta L}$. Without using explicit matrix representations show that to first order in δL the Lorentz transformation $A = A_2 A_1^{-1}$ can be written as

$$A = I + \delta L + \frac{1}{2!} [L, \delta L] + \frac{1}{3!} [L, [L, \delta L]] + \frac{1}{4!} [L, [L, [L, \delta L]]] + \dots$$

Hint: The early terms can be found by brute force, but alternatively consider the Taylor series expansion in λ of the operator $A(\lambda) = e^{\lambda(L+\delta L)} e^{-\lambda L}$ and then put $\lambda = 1$.

11.10 Apply the result of the previous problem to a purely algebraic derivation of (11.116) on Thomas precession.

(a) With

$$L = -\frac{\boldsymbol{\beta} \cdot \mathbf{K}(\tanh^{-1} \beta)}{\beta}$$

$$L + \delta L = -\frac{(\boldsymbol{\beta} + \delta \boldsymbol{\beta}_{\parallel} + \delta \boldsymbol{\beta}_{\perp}) \cdot \mathbf{K}(\tanh^{-1} \beta')}{\beta'}$$

where $\beta' = \sqrt{(\boldsymbol{\beta} + \delta \boldsymbol{\beta}_{\parallel})^2 + (\delta \boldsymbol{\beta}_{\perp})^2}$, show that

$$\delta L = -\gamma^2 \delta \boldsymbol{\beta}_{\parallel} \cdot \mathbf{K} - \frac{\delta \boldsymbol{\beta}_{\perp} \cdot \mathbf{K}(\tanh^{-1} \beta)}{\beta}$$

(b) Using the commutation relations for \mathbf{K} and \mathbf{S} , show that

$$C_1 = [L, \delta L] = -\left(\frac{\tanh^{-1} \beta}{\beta}\right)^2 (\boldsymbol{\beta} \times \delta \boldsymbol{\beta}_{\perp}) \cdot \mathbf{S}$$

$$C_2 = [L, C_1] = (\tanh^{-1} \beta)^2 \delta L_{\perp}$$

$$C_3 = [L, C_2] = (\tanh^{-1} \beta)^2 C_1$$

$$C_4 = [L, C_3] = (\tanh^{-1} \beta)^4 \delta L_{\perp}$$

where δL_{\perp} is the term in δL involving $\delta \boldsymbol{\beta}_{\perp}$.

(c) Sum the series of terms for $A_T = A_2 A_1^{-1}$ to obtain

$$A_T = I - (\gamma^2 \delta \boldsymbol{\beta}_{\parallel} + \gamma \delta \boldsymbol{\beta}_{\perp}) \cdot \mathbf{K} - \frac{\gamma^2}{\gamma + 1} (\boldsymbol{\beta} \times \delta \boldsymbol{\beta}_{\perp}) \cdot \mathbf{S}$$

correct to first order in $\delta \boldsymbol{\beta}$. [See D. Shelupsky, *Am. J. Phys.* **35**, 650 (1967).]

11.11 An infinitely long straight wire of negligible cross-sectional area is at rest and has a uniform linear charge density q_0 in the inertial frame K' . The frame K' (and the wire) move with a velocity \mathbf{v} parallel to the direction of the wire with respect to the laboratory frame K .

(a) Write down the electric and magnetic fields in cylindrical coordinates in the rest frame of the wire. Using the Lorentz transformation properties of the fields, find the components of the electric and magnetic fields in the laboratory.

(b) What are the charge and current densities associated with the wire in its rest frame? In the laboratory?

(c) From the laboratory charge and current densities, calculate directly the electric and magnetic fields in the laboratory. Compare with the results of (a).

11.12 (a) Express the Lorentz scalars $F^{\alpha\beta} F_{\alpha\beta}$, $\mathcal{F}^{\alpha\beta} F_{\alpha\beta}$, and $\mathcal{F}^{\alpha\beta} \mathcal{F}_{\alpha\beta}$ in terms of \mathbf{E} and \mathbf{B} . Are there any other invariants quadratic in the field strengths \mathbf{E} and \mathbf{B} ?

(b) Is it possible to have an electromagnetic field that appears as a purely electric field in one inertial frame and as a purely magnetic field in some other inertial frame? What are the criteria imposed on \mathbf{E} and \mathbf{B} such that there is an inertial frame in which there is no electric field?

(c) For macroscopic media, \mathbf{E} , \mathbf{B} form the field tensor $F^{\alpha\beta}$ and \mathbf{D} , \mathbf{H} the tensor $G^{\alpha\beta}$. What further invariants can be formed? What are their explicit expressions in terms of the 3-vector fields?

- 11.13 In a certain reference frame a static, uniform, electric field E_0 is parallel to the x axis, and a static, uniform, magnetic induction $B_0 = 2E_0$ lies in the x - y plane, making an angle θ with the x axis. Determine the relative velocity of a reference frame in which the electric and magnetic fields are parallel. What are the fields in that frame for $\theta \ll 1$ and $\theta \rightarrow (\pi/2)$?

- 11.14 In the rest frame of a conducting medium the current density satisfies Ohm's law, $\mathbf{J}' = \sigma \mathbf{E}'$, where σ is the conductivity and primes denote quantities in the rest frame.

(a) Taking into account the possibility of convection current as well as conduction current, show that the covariant generalization of Ohm's law is

$$\mathbf{J} - \frac{1}{c^2} (U_\beta J^\beta) \mathbf{U} = \frac{\sigma}{c} F^{\alpha\beta} U_\beta$$

where U^α is the 4-velocity of the medium.

(b) Show that if the medium has a velocity $\mathbf{v} = c\boldsymbol{\beta}$ with respect to some inertial frame that the 3-vector current in that frame is

$$\mathbf{J} = \gamma \sigma [\mathbf{E} + \boldsymbol{\beta} \times \mathbf{B} - \boldsymbol{\beta}(\boldsymbol{\beta} \cdot \mathbf{E})] + \rho \mathbf{v}$$

where ρ is the charge density observed in that frame.

(c) If the medium is uncharged in its rest frame ($\rho' = 0$), what is the charge density and the expression for \mathbf{J} in the frame of part (b)? This is the relativistic generalization of (10.8).

- 11.15 The electric and magnetic fields (11.152) of a charge in uniform motion can be obtained from Coulomb's law in the charge's rest frame and the fact that the field strength $F^{\alpha\beta}$ is an antisymmetric tensor of rank two without considering explicitly the Lorentz transformation. The idea is the following. For a charge in uniform motion the only relevant variables are the charge's 4-velocity U^α and the relative coordinate $X^\alpha = x_p^\alpha - x_q^\alpha$, where x_p^α and x_q^α are the 4-vector coordinates of the observation point and the charge, respectively. The only antisymmetric tensor that can be formed is $(X^\alpha U^\beta - X^\beta U^\alpha)$. Thus the electromagnetic field $F^{\alpha\beta}$ must be this tensor multiplied by some scalar function of the possible scalar products, $X_\alpha X^\alpha$, $X_\alpha U^\alpha$, $U_\alpha U^\alpha$.

(a) For the geometry of Fig. 11.8 the coordinates of P and q at a common time in K can be written $x_p^\alpha = (ct, \mathbf{b})$, $x_q^\alpha = (ct, \mathbf{v}t)$, with $\mathbf{b} \cdot \mathbf{v} = 0$. By considering the general form of $F^{\alpha\beta}$ in the rest frame of the charge, show that

$$F^{\alpha\beta} = \frac{q}{c} \frac{(X^\alpha U^\beta - X^\beta U^\alpha)}{\left[\frac{1}{c^2} (U_\alpha X^\alpha)^2 - X_\alpha X^\alpha \right]^{3/2}}$$

Verify that this yields the expressions (11.152) in the inertial frame K .

(b) Repeat the calculation, using as the starting point the common-time coordinates in the rest frame, $x_p'^\alpha = (ct', \mathbf{b} - \mathbf{v}t')$ and $x_q'^\alpha = (ct', 0)$. Show that

$$F^{\alpha\beta} = \frac{q}{c} \frac{(Y^\alpha U^\beta - Y^\beta U^\alpha)}{(-Y_\alpha Y^\alpha)^{3/2}}$$

where $Y'^\alpha = x_p'^\alpha - x_q'^\alpha$. Verify that the fields are the same as in part (a). Note that to obtain the results of (11.152) it is necessary to use the time t of the observation point P in K as the time parameter.

(c) Finally, consider the coordinate $x_p^\alpha = (ct, \mathbf{b})$ and the “retarded-time” coordinate $x_q^\alpha = [ct - R, \boldsymbol{\beta}(ct - R)]$ where R is the distance between P and q at the retarded time. Define the difference as $Z^\alpha = [R, \mathbf{b} - \boldsymbol{\beta}(ct - R)]$. Show that in terms of Z^α and U^α the field is

$$F^{\alpha\beta} = \frac{q}{c} \frac{(Z^\alpha U^\beta - Z^\beta U^\alpha)}{\left(\frac{1}{c} U_\alpha Z^\alpha\right)^3}$$

11.16 A particle of mass M and 4-momentum P decays into two particles of masses m_1 and m_2 .

(a) Use the conservation of energy and momentum in the form, $p_2 = P - p_1$, and the invariance of scalar products of 4-vectors to show that the total energy of the first particle in the rest frame of the decaying particle is

$$E_1 = \frac{M^2 + m_1^2 - m_2^2}{2M}$$

and that E_2 is obtained by interchanging m_1 and m_2 .

(b) Show that the kinetic energy T_i of the i th particle in the same frame is

$$T_i = \Delta M \left(1 - \frac{m_i}{M} - \frac{\Delta M}{2M} \right)$$

Where $\Delta M = M - m_1 - m_2$ is the mass excess or Q value of the process.

(c) The charged pi-meson ($M = 139.6$ MeV) decays into a mu-meson ($m_1 = 105.7$ MeV) and a neutrino ($m_2 = 0$). Calculate the kinetic energies of the mu-meson and the neutrino in the pi-meson's rest frame. The unique kinetic energy of the muon is the signature of a two-body decay. It entered importantly in the discovery of the pi-meson in photographic emulsions by Powell and co-workers in 1947.

11.17 The lambda particle (Λ) is a neutral baryon of mass $M = 1115$ MeV that decays with a lifetime of $\tau = 2.9 \times 10^{-10}$ sec into a nucleon of mass $m_1 \approx 939$ MeV and a pi-meson of mass $m_2 \approx 140$ MeV. It was first observed in flight by its charged decay mode $\Lambda \rightarrow p + \pi^-$ in cloud chambers. The charged tracks originate from a single point and have the appearance of an inverted vee or lambda. The particles' identities and momenta can be inferred from their ranges and curvature in the magnetic field of the chamber.

(a) Using conservation of momentum and energy and the invariance of scalar products of 4-vectors show that, if the opening angle θ between the two tracks is measured, the mass of the decaying particle can be found from the formula

$$M^2 = m_1^2 + m_2^2 + 2E_1 E_2 - 2p_1 p_2 \cos \theta$$

where here p_1 and p_2 are the magnitudes of the 3-momenta.

(b) A lambda particle is created with a total energy of 10 GeV in a collision in the top plate of a cloud chamber. How far on the average will it travel in the chamber before decaying? What range of opening angles will occur for a 10 GeV lambda if the decay is more or less isotropic in the lambda's rest frame?

11.18 If a system of mass M decays or transforms at rest into a number of particles, the sum of whose masses is less than M by an amount ΔM ,

(a) show that the maximum kinetic energy of the i th particle (mass m_i) is

$$(T_i)_{\max} = \Delta M \left(1 - \frac{m_i}{M} - \frac{\Delta M}{2M} \right)$$

(b) determine the maximum kinetic energies in MeV and also the ratios to ΔM for each of the particles in the following decays or transformations of particles at rest:

$$\mu \rightarrow e + \nu + \bar{\nu}$$

$$K^+ \rightarrow \pi^+ + \pi^- + \pi^+$$

$$K^{\pm} \rightarrow e^{\pm} + \pi^0 + \nu$$

$$K^{\pm} \rightarrow \mu^{\pm} + \pi^0 + \nu$$

$$p + \bar{p} \rightarrow 2\pi^+ + 2\pi^- + \pi^0$$

$$p + \bar{p} \rightarrow K^+ + K^- + 3\pi^0$$

11.19 The presence in the universe of an apparently uniform “sea” of black-body radiation at a temperature of roughly 3°K gives one mechanism for an upper limit on the energies of photons that have traveled an appreciable distance since their creation. Photon-photon collisions can result in the creation of a charged particle and its antiparticle (“pair creation”) if there is sufficient energy in the center of “mass” of the two photons. The lowest threshold and also the largest cross section occurs for a negaton-positon pair.

(a) Taking the energy of a typical 3°K photon to be $E = 2.5 \times 10^{-4} \text{ eV}$, calculate the energy for an incident photon such that there is energy just sufficient to make a negaton-positon pair. For photons with energies larger than this threshold value the cross section increases to a maximum of the order of $(e^2/mc^2)^2$ and then decreases slowly at higher energies. This interaction is one mechanism for the disappearance of such photons as they travel cosmological distances.

(b) There is some evidence for a diffuse X-ray background with photons having energies of several hundred eV or more. Beyond 1 keV the spectrum falls as E^{-n} with $n \approx 1.5$. Repeat the calculation of the threshold incident energy, assuming that the energy of the photon in the “sea” is 500 eV.

11.20 In a collision process a particle of mass m_2 , at rest in the laboratory, is struck by a particle of mass m_1 , momentum \mathbf{p}_{LAB} and total energy E_{LAB} . In the collision the two initial particles are transformed into two others of mass m_3 and m_4 . The configurations of the momentum vectors in the center of momentum (cm) frame (traditionally called the center of mass frame) and the laboratory frame are shown in the figure.

Problem 11.20

(a) Use invariant scalar products to show that the total energy W in the cm frame has its square given by

$$W^2 = m_1^2 + m_2^2 + 2m_2 E_{\text{LAB}}$$

and that the cms 3-momentum \mathbf{p}' is

$$\mathbf{p}' = \frac{m_2 \mathbf{p}_{\text{LAB}}}{W}$$

(b) Show that the Lorentz transformation parameters β_{cms} and γ_{cms} describing the velocity of the cms in the laboratory are

$$\beta_{\text{cms}} = \frac{\mathbf{p}_{\text{LAB}}}{m_2 + E_{\text{LAB}}}, \quad \gamma_{\text{cms}} = \frac{m_2 + E_{\text{LAB}}}{W}$$

(c) Show that the results of (a) and (b) reduce in the nonrelativistic limit to the familiar expressions,

$$W \approx m_1 + m_2 + \left(\frac{m_2}{m_1 + m_2} \right) \frac{p_{\text{LAB}}^2}{2m_1}$$

$$\mathbf{p}' \approx \left(\frac{m_2}{m_1 + m_2} \right) \mathbf{p}_{\text{LAB}}, \quad \beta_{\text{cms}} \approx \frac{\mathbf{p}_{\text{LAB}}}{m_1 + m_2}$$

11.21 The threshold kinetic energy T_{th} in the laboratory for a given reaction is the kinetic energy of the incident particle on a stationary target just sufficient to make the center of mass energy W equal to the sum of the rest energies of the particles in the final state. Calculate the threshold kinetic energies for the following processes. Express your answers in MeV or GeV and also in units of the rest energy of the incident particle (unless it is a massless particle).

(a) Pi-meson photoproduction, $\gamma p \rightarrow \pi^0 p$

$$(m_p = 938.5 \text{ MeV}, \quad m_{\pi^0} = 135.0 \text{ MeV})$$

(b) Nucleon-antinucleon pair production in nucleon-nucleon collisions, for example, $pp \rightarrow ppp\bar{p}$.

(c) Nucleon-antinucleon pair production in electron-electron collisions, $e^-e^- \rightarrow e^-e^-p\bar{p}$ and $e^+e^- \rightarrow p\bar{p}$ ($m_e = 0.511 \text{ MeV}$).

11.22 In colliding beam machines like the Intersecting Storage Ring (ISR) at CERN or the numerous e^+e^- storage rings, counter-rotating relativistic beams of particles are stored and made to collide more or less head on in one or more interaction regions. Let the particles in the two beams have masses m_1 and m_2 and momenta p_1 and p_2 , respectively, and let them intersect with an angle θ between the two beams.

(a) Show that, to order $(m/p)^2$ inclusive, the square of the total energy in the center of mass is

$$W^2 = 4p_1 p_2 \cos^2 \frac{\theta}{2} + (p_1 + p_2) \left(\frac{m_1^2}{p_1} + \frac{m_2^2}{p_2} \right)$$

(b) Show that the center of mass inertial frame has a velocity in the laboratory given by

$$\beta_{\text{cms}} = \frac{(p_1 + p_2) \sin \theta/2}{(E_1 + E_2) \sin \alpha}$$

where

$$\tan \alpha = \left(\frac{p_1 + p_2}{p_1 - p_2} \right) \tan \frac{\theta}{2}$$

The angle α is defined in the figure below.

(c) Check that the results of (b) agree with part (b) of Problem 11.20.

(d) If the crossing angle is $\theta = 20^\circ$ and $p_1 = p_2 = 30 \text{ GeV}/c$, is the laboratory frame a reasonable approximation to the cms? Consider, for example, a proton-proton inelastic collision involving pion production and examine the collinearity of two pions produced with equal and opposite momenta of $1 \text{ GeV}/c$ in the cms.

Problem 11.22

11.23 In an elastic scattering process the incident particle imparts energy to the stationary target. The energy ΔE lost by the incident particle appears as recoil kinetic energy of the target. In the notation of Problem 11.20, $m_3 = m_1$ and $m_4 = m_2$, while $\Delta E = T_4 = E_4 - m_4$.

(a) Show that ΔE can be expressed in the following different ways,

$$\Delta E = \frac{m_2}{W^2} p_{\text{LAB}}^2 (1 - \cos \theta')$$

$$\Delta E = \frac{2m_2 p_{\text{LAB}}^2 \cos^2 \theta_4}{W^2 + p_{\text{LAB}}^2 \sin^2 \theta_4}$$

$$\Delta E = \frac{Q^2}{2m_2}$$

where $Q^2 = -(p_1 - p_3)^2 = (\mathbf{p}_1 - \mathbf{p}_3)^2 - (E_1 - E_3)^2$ is the Lorentz invariant momentum transfer (squared).

(b) Show that for charged particles other than electrons incident on stationary electrons ($m_1 \gg m_2$) the maximum energy loss is approximately

$$\Delta E_{\text{max}} \approx 2\gamma^2 \beta^2 m_e$$

where γ and β are characteristic of the incident particle and $\gamma \ll (m_1/m_e)$. Give this result a simple interpretation by considering the relevant collision in the rest frame of the incident particle and then transforming back to the laboratory.

(c) For electron-electron collisions show that the maximum energy transfer is

$$\Delta E_{\text{max}}^{(e)} = (\gamma - 1)m_e$$

12

Dynamics of Relativistic Particles and Electromagnetic Fields

The kinematics of the special theory of relativity was developed in Chapter 11. We now turn to the question of dynamics. In the first part of the chapter we discuss the dynamics of charged particle motion in external electromagnetic fields. The Lagrangian approach to the equations of motion is presented mainly to introduce the concept of a Lorentz invariant action from which covariant dynamical equations can be derived. The transition to a Hamiltonian, with the definition of the canonical momentum, is then discussed. There follows a perhaps pedantic, or at least pedagogical, section on the Lorentz transformation properties of force and the dangers of pulling oneself up by Coulomb's bootstraps to the Maxwell equations. Then several sections are devoted to the motion of a charged particle in electric and magnetic fields. Motion in a uniform static magnetic field is followed by consideration of motion in a combination of electric and magnetic fields. Then the secular changes (drifts) of a particle's orbit caused by nonuniform magnetic fields and the adiabatic invariance of the linked flux are discussed. The problem of a relativistic Lagrangian for a system of interacting charged particles is addressed, and it is shown that to order v^2/c^2 it is possible to eliminate retardation effects and write a Lagrangian (the Darwin Lagrangian) in terms of the instantaneous positions and velocities of the particles.

In the last four sections of the chapter the emphasis is on fields. First, the Maxwell equations are derived from a suitable Lagrangian. Then, \therefore modified Lagrangian describing a "photon" with mass is presented and its consequences in resonant circuits, transmission lines, and cavities described. A covariant generalization of the Hamiltonian for fields is next discussed, along with the conservation laws of energy, momentum, and angular momentum for fields, both sourcefree and in interaction with charged particles. The chapter ends with a derivation of the invariant Green functions that form the basis of the solution of the wave equation with a given 4-vector current density as source.

12.1 Lagrangian and Hamiltonian for a Relativistic Charged Particle in External Electromagnetic Fields

The equations of motion,

$$\begin{aligned}\frac{d\mathbf{p}}{dt} &= e \left[\mathbf{E} + \frac{\mathbf{u}}{c} \times \mathbf{B} \right] \\ \frac{dE}{dt} &= e \mathbf{u} \cdot \mathbf{E}\end{aligned}\tag{12.1}$$

for a particle of charge e in external fields \mathbf{E} and \mathbf{B} can be written in the covariant form (11.144):

$$\frac{dU^\alpha}{d\tau} = \frac{e}{mc} F^{\alpha\beta} U_\beta \tag{12.2}$$

where m is the mass, τ is the proper time, and $U^\alpha = (\gamma c, \gamma \mathbf{u}) = p^\alpha/m$ is the 4-velocity of the particle.

Although the equations of motion (12.1) are sufficient to describe the general motion of a charged particle in external electromagnetic fields (neglecting the emission of radiation), it is useful to consider the formulation of the dynamics from the viewpoint of Lagrangian and Hamiltonian mechanics. The Lagrangian treatment of mechanics is based on the principle of least action or Hamilton's principle. In nonrelativistic mechanics the system is described by generalized coordinates $q_i(t)$ and velocities $\dot{q}_i(t)$. The Lagrangian L is a functional of q_i and \dot{q}_i and perhaps the time explicitly and the action A is defined as the time integral of L along a possible path of the system. The *principle of least action* states that the motion of a mechanical system is such that in going from a configuration a at time t_1 to a configuration b at time t_2 , the action

$$A = \int_{t_1}^{t_2} L[q_i(t), \dot{q}_i(t), t] dt \tag{12.3}$$

is an extremum. By considering small variations of the coordinates and velocities away from the actual path and requiring $\delta A = 0$, one obtains (see Goldstein, Chapter 2) the Euler-Lagrange equations of motion,

$$\frac{d}{dt} \left(\frac{\partial L}{\partial \dot{q}_i} \right) - \frac{\partial L}{\partial q_i} = 0 \tag{12.4}$$

We wish to extend the formalism to relativistic particle motion in a manner consistent with the special theory of relativity and leading for charged particles in external fields to (12.1) or (12.2). There are several levels of sophistication possible. The least sophisticated and most familiar treatment continues with ordinary coordinates, velocities, and time and generalizes from the nonrelativistic domain in a straightforward way. More sophisticated is a manifestly covariant discussion. We first present the elementary approach and then indicate the manifestly covariant treatment.

(a) *Elementary Approach to a Relativistic Lagrangian*

To obtain a relativistic Lagrangian for a particle in external fields we first consider the question of the Lorentz transformation properties of the Lagrangian. From the first postulate of special relativity the action integral must be a Lorentz scalar because the equations of motion are determined by the extremum condition, $\delta A = 0$. If we introduce the particle's proper time τ into (12.3) through $dt = \gamma d\tau$, the action integral becomes

$$A = \int_{\tau_1}^{\tau_2} \gamma L d\tau \quad (12.5)$$

Since proper time is invariant the condition that A also be invariant requires that γL be Lorentz invariant.

The Lagrangian for a free particle can be a function of the velocity of the particle and its mass, but cannot depend on its position. The only Lorentz invariant function of the velocity available is $U_\alpha U^\alpha = c^2$. Thus we conclude that the Lagrangian for a free particle is proportional to $\gamma^{-1} = \sqrt{1 - \beta^2}$. It is easily seen that

$$L_{\text{free}} = -mc^2 \sqrt{1 - \frac{u^2}{c^2}} \quad (12.6)$$

is the proper multiple of γ^{-1} to yield, through (12.4), the free-particle equation of motion,

$$\frac{d}{dt}(\gamma m \mathbf{u}) = 0$$

The action (12.5) is proportional to the integral of the proper time over the path from the initial proper time τ_1 to the final proper time τ_2 . This integral is Lorentz invariant, but depends on the path taken. For purposes of calculation, consider a reference frame in which the particle is initially at rest. From definition (11.26) of proper time it is clear that, if the particle stays at rest in that frame, the integral over proper time will be larger than if it moves with a nonzero velocity along its path. Consequently we see that a straight world line joining the initial and final points of the path gives the maximum integral over proper time or, with the negative sign in (12.6), a minimum for the action integral. This motion at constant velocity is, of course, the solution of the free-particle equation of motion.

The general requirement that γL be Lorentz invariant allows us to determine the Lagrangian for a relativistic charged particle in external electromagnetic fields, provided we know something about the Lagrangian (or equations of motion) for nonrelativistic motion in static fields. A slowly moving charged particle is influenced predominantly by the electric field that is derivable from the scalar potential Φ . The potential energy of interaction is $V = e\Phi$. Since the nonrelativistic Lagrangian is $(T - V)$, the interaction part L_{int} of the relativistic

Lagrangian must reduce in the nonrelativistic limit to

$$L_{\text{int}} \rightarrow L_{\text{int}}^{\text{NR}} = -e\Phi \quad (12.7)$$

Our problem thus becomes that of finding a Lorentz invariant expression for γL_{int} that reduces to (12.7) for nonrelativistic velocities. Since Φ is the time component of the 4-vector potential A^α , we anticipate that γL_{int} will involve the scalar product of A^α with some 4-vector. The only other 4-vectors available are the momentum and position vectors of the particle. Since gamma times the Lagrangian must be translationally invariant as well as Lorentz invariant, it cannot involve the coordinates explicitly. Hence the interaction Lagrangian must be*

$$\text{or} \quad \left. \begin{aligned} L_{\text{int}} &= -\frac{e}{\gamma c} U_\alpha A^\alpha \\ L_{\text{int}} &= -e\Phi + \frac{e}{c} \mathbf{u} \cdot \mathbf{A} \end{aligned} \right\} \quad (12.8)$$

The combination of (12.6) and (12.8) yields the complete relativistic Lagrangian for a charged particle:

$$L = -mc^2 \sqrt{1 - \frac{u^2}{c^2}} + \frac{e}{c} \mathbf{u} \cdot \mathbf{A} - e\Phi \quad (12.9)$$

Verification that (12.9) does indeed lead to the Lorentz force equation will be left as an exercise for the reader. Use must be made of the convective derivative $[d/dt = (\partial/\partial t) + \mathbf{u} \cdot \nabla]$ and the standard definitions of the fields in terms of the potentials.

The canonical momentum \mathbf{P} conjugate to the position coordinate \mathbf{x} is obtained by the definition,

$$P_i \equiv \frac{\partial L}{\partial u_i} = \gamma m u_i + \frac{e}{c} A_i \quad (12.10)$$

Thus the conjugate momentum is

$$\mathbf{P} = \mathbf{p} + \frac{e}{c} \mathbf{A} \quad (12.11)$$

where $\mathbf{p} = \gamma m \mathbf{u}$ is the ordinary kinetic momentum. The Hamiltonian H is a function of the coordinate \mathbf{x} and its conjugate momentum \mathbf{P} and is a constant of

* Without appealing to the nonrelativistic limit this form of L_{int} can be written down by demanding that γL_{int} be a Lorentz invariant that is (1) linear in the charge of the particle, (2) linear in the electromagnetic potentials, (3) translationally invariant, and (4) a function of no higher than the first time derivative of the particle coordinates. The reader may consider the possibility of an interaction Lagrangian satisfying these conditions, but linear in the field strengths $F^{\alpha\beta}$, rather than the potentials A^α .

the motion if the Lagrangian is not an explicit function of time. The Hamiltonian is defined in terms of the Lagrangian as

$$H = \mathbf{P} \cdot \mathbf{u} - L \quad (12.12)$$

The velocity \mathbf{u} must be eliminated from (12.12) in favor of \mathbf{P} and \mathbf{x} . From (12.10) or (12.11) we find that

$$\mathbf{u} = \frac{c\mathbf{P} - e\mathbf{A}}{\sqrt{\left(\mathbf{P} - \frac{e\mathbf{A}}{c}\right)^2 + m^2c^2}} \quad (12.13)$$

When this is substituted into (12.12) and into L (12.9), the Hamiltonian takes on the form:

$$H = \sqrt{(c\mathbf{P} - e\mathbf{A})^2 + m^2c^4} + e\Phi \quad (12.14)$$

Again the reader may verify that Hamilton's equations of motion can be combined to yield the Lorentz force equation. Equation (12.14) is an expression for the total energy W of the particle. It differs from the free-particle energy by the addition of the potential energy $e\Phi$ and by the replacement $\mathbf{p} \rightarrow [\mathbf{P} - (e/c)\mathbf{A}]$. These two modifications are actually only one 4-vector change. This can be seen by transposing $e\Phi$ in (12.14) and squaring both sides. Then

$$(W - e\Phi)^2 - (c\mathbf{P} - e\mathbf{A})^2 = (mc^2)^2 \quad (12.15)$$

This is just the 4-vector scalar product,

$$p_\alpha p^\alpha = (mc)^2 \quad (12.16)$$

where

$$p^\alpha \equiv \left(\frac{E}{c}, \mathbf{p} \right) = \left(\frac{1}{c} (W - e\Phi), \mathbf{P} - \frac{e}{c} \mathbf{A} \right) \quad (12.17)$$

We see that the total energy W/c acts as the time component of a canonically conjugate 4-momentum P^α of which \mathbf{P} given by (12.11) is the space part. A manifestly covariant approach, discussed in the following paragraphs and also in Problem 12.1 leads naturally to this 4-momentum.

In passing we remark on the question of gauge transformations. Obviously the equations of motion (12.1) are invariant under a gauge transformation of the potentials. Since the Lagrangian (12.8) involves the potentials explicitly, it is not invariant. In spite of this lack of invariance of L under gauge transformations it can be shown (Problem 12.2) that the change in the Lagrangian is of such a form (a total time derivative) that it does not alter the action integral or the equations of motion.

(b) Manifestly Covariant Treatment of the Relativistic Lagrangian

To make a manifestly covariant description the customary variables \mathbf{x} and \mathbf{u} are replaced by the 4-vectors x^α and U^α . The free-particle Lagrangian (12.6) can

be written in terms of U^α as

$$L_{\text{free}} = -\frac{mc}{\gamma} \sqrt{U_\alpha U^\alpha} \quad (12.18)$$

Then the action integral (12.5) would be

$$A = -mc \int_{\tau_1}^{\tau_2} \sqrt{U_\alpha U^\alpha} d\tau \quad (12.19)$$

This manifestly invariant form might be thought to provide the starting point for a variational calculation leading to the equation of motion, $dU^\alpha/d\tau = 0$. There is, however, the equation of constraint,

$$U_\alpha U^\alpha = c^2 \quad (12.20a)$$

or the equivalent constraint,

$$U_\alpha \frac{dU^\alpha}{d\tau} = 0 \quad (12.20b)$$

on the equations of motion. This can be incorporated by the Lagrange multiplier technique, but we pursue a different, equivalent procedure. The integrand in (12.19) is

$$\sqrt{U_\alpha U^\alpha} d\tau = \sqrt{\frac{dx_\alpha}{d\tau} \frac{dx^\alpha}{d\tau}} d\tau = \sqrt{g^{\alpha\beta} dx_\alpha dx_\beta}$$

that is, the infinitesimal length element in 4-space. This suggests that the action integral (12.19) be replaced by

$$A = -mc \int_{s_1}^{s_2} \sqrt{g^{\alpha\beta} \frac{dx_\alpha}{ds} \frac{dx_\beta}{ds}} ds \quad (12.21)$$

where the 4-vector coordinate of the particle is $x^\alpha(s)$, with s a parameter that is a monotonically increasing function of τ , but otherwise arbitrary. The action integral is an integral along the world line of the particle, and the principle of least action is the statement that the actual path is the longest path, namely the geodesic.* The Lagrangian variables are now x^α and “the velocity” dx^α/ds , but s is considered as arbitrary. Only after the calculus of variations has been completed do we identify

$$\sqrt{g^{\alpha\beta} \frac{dx_\alpha}{ds} \frac{dx_\beta}{ds}} ds = c d\tau \quad (12.22)$$

and so impose the constraint (12.20). A straightforward variational calculation with (12.21) yields the Euler-Lagrange equations,

$$mc \frac{d}{ds} \left[\frac{dx^\alpha/ds}{\sqrt{\frac{dx_\beta}{ds} \frac{dx^\beta}{ds}}} \right] = 0$$

* The geodesic is the longest path or longest proper time for timelike separation of events. See *Rohrlich*, pp. 277–278.

or

$$m \frac{d^2 x^\alpha}{d\tau^2} = 0$$

as expected for free-particle motion.

For a charged particle in an external field the form of the Lagrangian (12.8) suggests that the manifestly covariant form of the action integral is

$$A = - \int_{s_1}^{s_2} \left[mc \sqrt{g^{\alpha\beta} \frac{dx_\alpha}{ds} \frac{dx_\beta}{ds}} + \frac{e}{c} \frac{dx_\alpha}{ds} A^\alpha(x) \right] ds \quad (12.23)$$

Hamilton's principle yields the Euler-Lagrange equations,

$$\frac{d}{ds} \left(\frac{\partial \tilde{L}}{\partial \left(\frac{dx_\alpha}{ds} \right)} \right) - \partial^\alpha \tilde{L} = 0 \quad (12.24)$$

where the Lagrangian is

$$\tilde{L} = - \left[mc \sqrt{g^{\alpha\beta} \frac{dx_\alpha}{ds} \frac{dx_\beta}{ds}} + \frac{e}{c} \frac{dx_\alpha}{ds} A^\alpha(x) \right] \quad (12.25)$$

Explicitly, (12.24), upon division by the square root and use of (12.22), becomes

$$m \frac{d^2 x^\alpha}{d\tau^2} + \frac{e}{c} \frac{dA^\alpha(x)}{d\tau} - \frac{e}{c} \frac{dx_\beta}{d\tau} \partial^\alpha A^\beta(x) = 0$$

Since $dA^\alpha/d\tau = (dx_\beta/d\tau) \partial^\beta A^\alpha$, this equation can be written as

$$m \frac{d^2 x^\alpha}{d\tau^2} = \frac{e}{c} (\partial^\alpha A^\beta - \partial^\beta A^\alpha) \frac{dx_\beta}{d\tau} \quad (12.26)$$

which is the covariant equation of motion (12.2) in different notation.

The transition to the conjugate momenta and a Hamiltonian is simple enough, but has problems of interpretation. The conjugate momentum 4-vector is defined by

$$P^\alpha = - \frac{\partial \tilde{L}}{\partial \left(\frac{dx_\alpha}{ds} \right)} = m U^\alpha + \frac{e}{c} A^\alpha \quad (12.27)$$

The minus sign is introduced so that (12.27) conforms with (12.11); its origin can be traced to the properties of the Lorentz space-time. A Hamiltonian can be defined by

$$\tilde{H} = \frac{1}{2} (P_\alpha U^\alpha + \tilde{L}) \quad (12.28)$$

Elimination of U^α by means of (12.27) leads to the expression,

$$\tilde{H} = \frac{1}{2m} \left(P_\alpha - \frac{eA_\alpha}{c} \right) \left(P^\alpha - \frac{eA^\alpha}{c} \right) - \frac{1}{2} mc^2 \quad (12.29)$$

Hamilton's equations are

$$\left. \begin{aligned} \frac{dx^\alpha}{d\tau} &= \frac{\partial \tilde{H}}{\partial P_\alpha} = \frac{1}{m} \left(P^\alpha - \frac{e}{c} A^\alpha \right) \\ \text{and} \quad \frac{dP^\alpha}{d\tau} &= - \frac{\partial \tilde{H}}{\partial x_\alpha} = \frac{e}{mc} \left(P_\beta - \frac{e A_\beta}{c} \right) \partial^\alpha A^\beta \end{aligned} \right\} \quad (12.30)$$

This can be immediately shown to be equivalent to the Euler-Lagrange equation (12.26).

While the above Hamiltonian is formally satisfactory, it has several problems. The first is that it is by definition a Lorentz scalar, not an energylike quantity. Second, use of (12.20a) and (12.27) shows that $\tilde{H} \equiv 0$. Clearly, such a Hamiltonian formulation differs considerably from the familiar nonrelativistic version. The reader can refer to *Barut*, pp. 68 ff, for a discussion of this and other alternative Hamiltonians.

12.2 On the Question of Obtaining the Magnetic Field, Magnetic Force, and the Maxwell Equations from Coulomb's Law and Special Relativity

At present it is popular in undergraduate texts and elsewhere* to attempt to derive magnetic fields and even the Maxwell equations from Coulomb's law of electrostatics and the kinematics of special relativity. It should be immediately apparent that without additional assumptions this is impossible. An obvious counter-example is gravitation. In the nonrelativistic limit the force law has the same space-time properties as Coulomb's law, yet the relativistic theory of gravitation involves *potentials* that transform second rank tensors, not 4-vectors.

The confusion arises chiefly because the Lorentz transformation properties of force are such that a *magnetic-like force term* appears when the force in one inertial frame is expressed in terms of the force in another frame. It is tempting to give this extra force term an independent existence and so identify the magnetic field as a separate entity. But such a step is unwarranted without additional assumptions. Consider the motion of a particle under the action of an external force whose nature is unspecified, except that it is a proper force in special relativity. In the inertial frame K' the equation of motion is

$$\frac{d\mathbf{p}'}{dt'} = \mathbf{F}' \quad (12.31)$$

* See, for example, Chapter 6 of P. Lorrain and D. R. Corson, *Electromagnetic Fields and Waves*, 2nd edition, W. H. Freeman, San Francisco (1970) and A. Bergstrom, *Nuovo Cimento* **14B**, 235 (1973).

Fig. 12.1

where the particle's velocity is $\mathbf{u}' = d\mathbf{x}'/dt'$ and its momentum is $\mathbf{p}' = \gamma_u m \mathbf{u}'$. If we now consider the equation of motion of the particle in the inertial frame K , as shown in Fig. 12.1, we find by direct calculation using the known Lorentz transformation properties of momentum [either via $dp^\alpha/d\tau$ or directly from p^α and the relation $t' = \gamma_v(t - \mathbf{v} \cdot \mathbf{x}/c^2)$] that the time rate of change of momentum in K can be expressed in terms of the force in K' as

$$\begin{aligned} \left(\frac{d\mathbf{p}}{dt}\right)_\parallel &= \left(\frac{d\mathbf{p}'}{dt'}\right)_\parallel + \frac{\gamma_v}{c^2} \left[\mathbf{u} \times \left(\mathbf{v} \times \frac{d\mathbf{p}'}{dt'} \right) \right]_\parallel \\ \left(\frac{d\mathbf{p}}{dt}\right)_\perp &= \gamma_v \left(\frac{d\mathbf{p}'}{dt'}\right)_\perp + \frac{\gamma_v}{c^2} \left[\mathbf{u} \times \left(\mathbf{v} \times \frac{d\mathbf{p}'}{dt'} \right) \right]_\perp \end{aligned} \quad (12.32)$$

Here \mathbf{u} is the velocity of the particle in K , while \mathbf{v} and γ_v are associated with the Lorentz transformation from K to K' . Equations (12.32) are written deliberately with $d\mathbf{p}'/dt'$ on the right-hand side instead of \mathbf{F}' to emphasize the kinematic nature of the equations and of the second, velocity-dependent term.

The common, erroneous path is to say that in K' the particle is moving nonrelativistically and hence experiences an electrostatic force, $\mathbf{F}' = q\mathbf{E}'$, where q is its charge and \mathbf{E}' is the electric field in that frame. Then, depending upon whether one is neglecting terms of order v^2/c^2 or not, one *defines* the magnetic field in the frame K as

$$\mathbf{B} = \frac{\gamma_v}{qc} \left(\mathbf{v} \times \frac{d\mathbf{p}'}{dt'} \right) = \frac{\gamma_v}{c} \mathbf{v} \times \mathbf{E}' \quad (12.33)$$

and apparently arrives from the second term in (12.32) at the magnetic term of the Lorentz force,

$$\frac{q}{c} \mathbf{u} \times \mathbf{B}$$

The reader may think that this seems quite reasonable, especially when he notes from (11.149) that (12.33) is the correct expression for the magnetic field in K if

there is a purely electric field \mathbf{E}' in K' . But what if there had been a magnetic field \mathbf{B}' in K' ? The force \mathbf{F}' would still be $\mathbf{F}' = q\mathbf{E}'$ provided $\mathbf{u}' \approx 0$, but (12.33) would no longer be the correct magnetic field in K .*

The fact is that it is impossible from (12.32) alone to deduce the existence of the magnetic field \mathbf{B} and the magnetic force $q(\mathbf{u} \times \mathbf{B})/c$. Other assumptions are necessary. One key assumption or experimental fact is that in a frame K where all the *source charges* producing an electric field \mathbf{E} are *at rest*, the force on a charge q is given by $\mathbf{F} = q\mathbf{E}$, *independent of the velocity \mathbf{u} of the charge in that frame*. A reasonably good treatment of the derivation of the Maxwell equations using special relativity with all the assumptions visible is given by Frisch and Wilets.†

An explicit counter-example that also illustrates the techniques of the preceding section is the interaction of a particle with a *Lorentz scalar potential* $\phi(x)$. The Lagrangians L or \tilde{L} are

$$L = -mc^2 \sqrt{1 - \frac{u^2}{c^2}} e^{g\phi(x)/mc^2} \quad (12.34)$$

$$\tilde{L} = -mc \sqrt{g^{\alpha\beta} \frac{dx_\alpha}{ds} \frac{dx_\beta}{ds}} e^{g\phi(x)/mc^2}$$

where g is a coupling constant analogous to the electric charge. The covariant equations of motion following from (12.24) with the Lagrangian (12.34) are

$$m \frac{dU^\alpha}{d\tau} = g \left(\partial^\alpha \phi - \frac{1}{c^2} U^\alpha U_\beta \partial^\beta \phi \right) \quad (12.35)$$

while the explicit space-time equations are

$$\frac{d\mathbf{p}}{dt} = -\frac{g}{\gamma_u} \nabla \phi - \frac{g\mathbf{p}}{mc^2} \left(\frac{\partial \phi}{\partial t} + \mathbf{u} \cdot \nabla \phi \right) \quad (12.36)$$

and $dE/dt = \mathbf{u} \cdot d\mathbf{p}/dt$. For nonrelativistic motion, (12.36) has the appearance of the Coulomb force law or Newton's law of gravitation with ϕ as the potential. But for relativistic motion, the force is not the Lorentz force law; it involves the 4-vector $\partial^\alpha \phi$, not the second-rank field strength tensor $F^{\alpha\beta}$. Note, too, that even in a frame where the "sources" are at rest and hence ϕ is independent of time, the force on the particle is velocity-dependent, another difference from the Lorentz force.

* This means that the second terms in (12.32) do not give the whole of the magnetic force in K . Some of the $q(\mathbf{u} \times \mathbf{B})/c$ comes from the first terms. It is, of course, true that the Lorentz force law is consistent with (12.32). The reader should verify that $\mathbf{F}' = q(\mathbf{E}' + \mathbf{u}' \times \mathbf{B}'/c)$ in K' leads via (12.32) to $\mathbf{F} = q(\mathbf{E} + \mathbf{u} \times \mathbf{B}/c)$ in K .

† D. H. Frisch and L. Wilets, *Am. J. Phys.* **24**, 574 (1956). See also J. R. Tessman, *Am. J. Phys.* **34**, 1048 (1966). An informal and heuristic discussion, but with all the empirical facts and assumptions clearly laid out, can be found in Chapter 3 of M. Schwartz, *Principles of Electrodynamics*, McGraw-Hill, New York (1972).

In spite of the differences from electromagnetism this Lorentz scalar potential example conforms to the requirements of (12.32). In the frame K there is an apparent magnetic-like force. But there is no independent entity \mathbf{B} . The force in any frame is given in terms of the *four* components of $\partial^\alpha \phi$, *not the six* components of $F^{\alpha\beta}$. Further consideration of this example is left to Problem 12.3.

12.3 Motion in a Uniform, Static, Magnetic Field

As a first important example of the dynamics of charged particles in electromagnetic fields we consider the motion in a uniform, static, magnetic induction \mathbf{B} . The equations of motion (12.1) are

$$\frac{d\mathbf{p}}{dt} = \frac{e}{c} \mathbf{v} \times \mathbf{B}, \quad \frac{dE}{dt} = 0 \quad (12.37)$$

where here the particle's velocity is denoted by \mathbf{v} . Since the energy is constant in time, the magnitude of the velocity is constant and so is γ . Then the first equation can be written

$$\frac{d\mathbf{v}}{dt} = \mathbf{v} \times \boldsymbol{\omega}_B \quad (12.38)$$

where

$$\boldsymbol{\omega}_B = \frac{e\mathbf{B}}{\gamma mc} = \frac{ec\mathbf{B}}{E} \quad (12.39)$$

is the gyration or precession frequency. The motion described by (12.38) is a circular motion perpendicular to \mathbf{B} and a uniform translation parallel to \mathbf{B} . The solution for the velocity is easily shown to be

$$\mathbf{v}(t) = v_{\parallel} \boldsymbol{\epsilon}_3 + \omega_B a (\boldsymbol{\epsilon}_1 - i\boldsymbol{\epsilon}_2) e^{-i\omega_B t} \quad (12.40)$$

where $\boldsymbol{\epsilon}_3$ is a unit vector parallel to the field, $\boldsymbol{\epsilon}_1$ and $\boldsymbol{\epsilon}_2$ are the other orthogonal unit vectors, v_{\parallel} is the velocity component along the field, and a is the gyration radius. The convention is that the real part of the equation is to be taken. Then one can see that (12.40) represents a *counterclockwise rotation* (for positive charge e) when viewed in the direction of \mathbf{B} . Another integration yields the displacement of the particle,

$$\mathbf{x}(t) = \mathbf{X}_0 + v_{\parallel} t \boldsymbol{\epsilon}_3 + ia(\boldsymbol{\epsilon}_1 - i\boldsymbol{\epsilon}_2) e^{-i\omega_B t} \quad (12.41)$$

The path is a helix of radius a and pitch angle $\alpha = \tan^{-1}(v_{\parallel}/\omega_B a)$. The magnitude of the gyration radius a depends on the magnetic induction \mathbf{B} and the transverse momentum \mathbf{p}_{\perp} of the particle. From (12.39) and (12.40) it is evident that

$$cp_{\perp} = eBa$$

This form is convenient for the determination of particle momenta. The radius of curvature of the path of a charged particle in a known B allows the determination of its momentum. For particles with charge the same in magnitude as the electronic charge, the momentum can be written numerically as

$$p_{\perp}(\text{MeV}/c) = 3.00 \times 10^{-4} B a \text{ (gauss-cm)} \quad (12.42)$$

12.4 Motion in Combined, Uniform, Static Electric and Magnetic Fields

We now consider a charged particle moving in a combination of electric and magnetic fields \mathbf{E} and \mathbf{B} , both uniform and static, but in general not parallel. As an important special case, *perpendicular fields* will be treated first. The force equation (12.1) shows that the particle's energy is not constant in time. Consequently we cannot obtain a simple equation for the velocity, as was done for a static magnetic field. But an appropriate Lorentz transformation simplifies the equations of motion. Consider a Lorentz transformation to a coordinate frame K' moving with a velocity \mathbf{u} with respect to the original frame. Then the Lorentz force equation for the particle in K' is

$$\frac{d\mathbf{p}'}{dt'} = e \left(\mathbf{E}' + \frac{\mathbf{v}' \times \mathbf{B}'}{c} \right)$$

where the primed variables are referred to the system K' . The fields \mathbf{E}' and \mathbf{B}' are given by relations (11.149) with \mathbf{v} replaced by \mathbf{u} . Let us first suppose that $|\mathbf{E}| < |\mathbf{B}|$. If \mathbf{u} is now chosen perpendicular to the orthogonal vectors \mathbf{E} and \mathbf{B} ,

$$\mathbf{u} = c \frac{(\mathbf{E} \times \mathbf{B})}{B^2} \quad (12.43)$$

we find the fields in K' to be

$$\left. \begin{aligned} \mathbf{E}'_{\parallel} &= 0, & \mathbf{E}'_{\perp} &= \gamma \left(\mathbf{E} + \frac{\mathbf{u}}{c} \times \mathbf{B} \right) = 0 \\ \mathbf{B}'_{\parallel} &= 0, & \mathbf{B}'_{\perp} &= \frac{1}{\gamma} \mathbf{B} = \left(\frac{B^2 - E^2}{B^2} \right)^{1/2} \mathbf{B} \end{aligned} \right\} \quad (12.44)$$

where \parallel and \perp refer to the direction of \mathbf{u} . In the frame K' the only field acting is a static magnetic field \mathbf{B}' which points in the same direction as \mathbf{B} , but is weaker than \mathbf{B} by a factor γ^{-1} . Thus the motion in K' is the same as that considered in the previous section, namely a spiraling around the lines of force. As viewed from the original coordinate system, this gyration is accompanied by a uniform "drift" \mathbf{u} perpendicular to \mathbf{E} and \mathbf{B} given by (12.43). This drift is sometimes called the $\mathbf{E} \times \mathbf{B}$ drift. It has already been considered for a conducting fluid in another context in Section 10.3. The drift can be understood qualitatively by noting that a particle which starts gyrating

Fig. 12.2 $\mathbf{E} \times \mathbf{B}$ drift of charged particles in crossed fields.

around \mathbf{B} is accelerated by the electric field, gains energy, and so moves in a path with a larger radius for roughly half of its cycle. On the other half, the electric field decelerates it, causing it to lose energy and so move in a tighter arc. The combination of arcs produces a translation perpendicular to \mathbf{E} and \mathbf{B} as shown in Fig. 12.2. The direction of drift is independent of the sign of the charge of the particle.

The drift velocity \mathbf{u} (12.43) has physical meaning only if it is less than the velocity of light, i.e., only if $|\mathbf{E}| < |\mathbf{B}|$. If $|\mathbf{E}| > |\mathbf{B}|$, the electric field is so strong that the particle is continually accelerated in the direction of \mathbf{E} and its average energy continues to increase with time. To see this we consider a Lorentz transformation from the original frame to a system K'' moving with a velocity

$$\mathbf{u}' = c \frac{(\mathbf{E} \times \mathbf{B})}{E^2} \quad (12.45)$$

relative to the first. In this frame the electric and magnetic fields are

$$\left. \begin{aligned} \mathbf{E}_{\parallel}'' &= 0, & \mathbf{E}_{\perp}'' &= \frac{1}{\gamma'} \mathbf{E} = \left(\frac{E^2 - B^2}{E^2} \right)^{1/2} \mathbf{E} \\ \mathbf{B}_{\parallel}'' &= 0, & \mathbf{B}_{\perp}'' &= \gamma' \left(\mathbf{B} - \frac{\mathbf{u}' \times \mathbf{E}}{c} \right) = 0 \end{aligned} \right\} \quad (12.46)$$

Thus in the system K'' the particle is acted on by a purely electrostatic field which causes hyperbolic motion with ever-increasing velocity (see Problem 12.4).

The fact that a particle can move through crossed \mathbf{E} and \mathbf{B} fields with the uniform velocity $u = cE/B$ provides the possibility of selecting charged particles according to velocity. If a beam of particles having a spread in velocities is normally incident on a region containing uniform crossed electric and magnetic fields, only those particles with velocities equal to cE/B will travel without deflection. Suitable entrance and exit slits will then allow only a very narrow band of velocities around cE/B to be transmitted, the resolution depending on the geometry, the velocities desired, and the field strengths. When combined with momentum selectors, such as a deflecting magnet, these $\mathbf{E} \times \mathbf{B}$ velocity

selectors can separate a very pure and monoenergetic beam of particles of a definite mass from a mixed beam of particles with different masses and momenta. Large-scale devices of this sort are commonly used to provide experimental beams of particles produced in very high-energy accelerators.

If \mathbf{E} has a component parallel to \mathbf{B} , the behavior of the particle cannot be understood in such simple terms as above. The scalar product $\mathbf{E} \cdot \mathbf{B}$ is a Lorentz invariant quantity (see Problem 11.12), as is $(B^2 - E^2)$. When the fields were perpendicular ($\mathbf{E} \cdot \mathbf{B} = 0$), it was possible to find a Lorentz frame where $\mathbf{E} = 0$ if $|\mathbf{B}| > |\mathbf{E}|$, or $\mathbf{B} = 0$ if $|\mathbf{E}| > |\mathbf{B}|$. In those coordinate frames the motion was relatively simple. If $\mathbf{E} \cdot \mathbf{B} \neq 0$, electric and magnetic fields will exist simultaneously in all Lorentz frames, the angle between the fields remaining acute or obtuse depending on its value in the original coordinate frame. Consequently motion in combined fields must be considered. When the fields are static and uniform, it is a straightforward matter to obtain a solution for the motion in cartesian components. This will be left for Problem 12.7.

12.5 Particle Drifts in Nonuniform, Static Magnetic Fields

In astrophysical and thermonuclear applications it is of considerable interest to know how particles behave in magnetic fields which vary in space. Often the variations are gentle enough that a perturbation solution to the motion, first given by Alfvén, is an adequate approximation. “Gentle enough” generally means that the distance over which \mathbf{B} changes appreciably in magnitude or direction is large compared to the gyration radius a of the particle. Then the lowest-order approximation to the motion is a spiraling around the lines of force at a frequency given by the local value of the magnetic induction. In the next approximation, slow changes occur in the orbit which can be described as a drifting of the guiding center.

The first type of spatial variation of the field to be considered is a gradient perpendicular to the direction of \mathbf{B} . Let the gradient at the point of interest be in the direction of the unit vector \mathbf{n} , with $\mathbf{n} \cdot \mathbf{B} = 0$. Then, to first order, the gyration frequency can be written

$$\omega_B(\mathbf{x}) = \frac{e}{\gamma mc} B(\mathbf{x}) \approx \omega_0 \left[1 + \frac{1}{B_0} \left(\frac{\partial B}{\partial \xi} \right)_0 \mathbf{n} \cdot \mathbf{x} \right] \quad (12.47)$$

In (12.47) ξ is the coordinate in the direction \mathbf{n} , and the expansion is about the origin of coordinates where $\omega_B = \omega_0$. Since the direction of \mathbf{B} is unchanged, the motion parallel to \mathbf{B} remains a uniform translation. Consequently we consider only modifications in the transverse motion. Writing $\mathbf{v}_\perp = \mathbf{v}_0 + \mathbf{v}_1$, where \mathbf{v}_0 is the uniform-field transverse velocity and \mathbf{v}_1 is a small correction term, we can substitute (12.47) into the force equation

$$\frac{d\mathbf{v}_\perp}{dt} = \mathbf{v}_\perp \times \omega_B(\mathbf{x}) \quad (12.48)$$

and, keeping only first-order terms, obtain the approximate result,

$$\frac{d\mathbf{v}_1}{dt} \simeq \left[\mathbf{v}_1 + \mathbf{v}_0(\mathbf{n} \cdot \mathbf{x}_0) \frac{1}{B_0} \left(\frac{\partial B}{\partial \xi} \right)_0 \right] \times \boldsymbol{\omega}_0 \quad (12.49)$$

From (12.40) and (12.41) it is easy to see that for a uniform field the transverse velocity \mathbf{v}_0 and coordinate \mathbf{x}_0 are related by

$$\left. \begin{aligned} \mathbf{v}_0 &= -\boldsymbol{\omega}_0 \times (\mathbf{x}_0 - \mathbf{X}) \\ (\mathbf{x}_0 - \mathbf{X}) &= \frac{1}{\omega_0^2} (\boldsymbol{\omega}_0 \times \mathbf{v}_0) \end{aligned} \right\} \quad (12.50)$$

where \mathbf{X} is the center of gyration of the unperturbed circular motion ($\mathbf{X} = 0$ here). If $(\boldsymbol{\omega}_0 \times \mathbf{v}_0)$ is eliminated in (12.49) in favor of \mathbf{x}_0 , we obtain

$$\frac{d\mathbf{v}_1}{dt} \simeq \left[\mathbf{v}_1 - \frac{1}{B_0} \left(\frac{\partial B}{\partial \xi} \right)_0 \boldsymbol{\omega}_0 \times \mathbf{x}_0 (\mathbf{n} \cdot \mathbf{x}_0) \right] \times \boldsymbol{\omega}_0 \quad (12.51)$$

This shows that, apart from oscillatory terms, \mathbf{v}_1 has a nonzero average value,

$$\mathbf{v}_G \equiv \langle \mathbf{v}_1 \rangle = \frac{1}{B_0} \left(\frac{\partial B}{\partial \xi} \right)_0 \boldsymbol{\omega}_0 \times \langle (\mathbf{x}_0)_\perp (\mathbf{n} \cdot \mathbf{x}_0) \rangle \quad (12.52)$$

To determine the average value of $(\mathbf{x}_0)_\perp (\mathbf{n} \cdot \mathbf{x}_0)$, it is necessary only to observe that the rectangular components of $(\mathbf{x}_0)_\perp$ oscillate sinusoidally with peak amplitude a and a phase difference of 90° . Hence only the component of $(\mathbf{x}_0)_\perp$ parallel to \mathbf{n} contributes to the average, and

$$\langle (\mathbf{x}_0)_\perp (\mathbf{n} \cdot \mathbf{x}_0) \rangle = \frac{a^2}{2} \mathbf{n} \quad (12.53)$$

Thus the gradient drift velocity is given by

$$\mathbf{v}_G = \frac{a^2}{2} \frac{1}{B_0} \left(\frac{\partial B}{\partial \xi} \right)_0 (\boldsymbol{\omega}_0 \times \mathbf{n}) \quad (12.54)$$

An alternative form, independent of coordinates, is

$$\frac{\mathbf{v}_G}{\omega_B a} = \frac{a}{2B^2} (\mathbf{B} \times \nabla_\perp B) \quad (12.55)$$

From (12.55) it is evident that, if the gradient of the field is such that $|\nabla B/B| \ll 1$, the drift velocity is small compared to the orbital velocity ($\omega_B a$). The particle spirals rapidly while its center of rotation moves slowly perpendicular to both \mathbf{B} and ∇B . The sense of the drift for positive particles is given by (12.55). For negatively charged particles the sign of the drift velocity is opposite; the sign change comes from the definition of ω_B . The gradient drift can be understood qualitatively from consideration of the variation of gyration radius as the particle moves in and out of regions of larger than average and smaller than average field strength. Figure 12.3 shows this qualitative behavior for both signs of charge.

Fig. 12.3 Drift of charged particles due to transverse gradient of magnetic field.

Another type of field variation which causes a drifting of the particle's guiding center is curvature of the lines of force. Consider the two-dimensional field shown in Fig. 12.4. It is locally independent of z . On the left-hand side of the figure is a constant, uniform magnetic induction \mathbf{B}_0 , parallel to the x axis. A particle spirals around the field lines with a gyration radius a and a velocity $\omega_B a$, while moving with a uniform velocity v_{\parallel} along the lines of force. We wish to treat that motion as a zero-order approximation to the motion of the particle in the field shown on the right-hand side of the figure, where the lines of force are curved with a local radius of curvature R which is large compared to a .

The first-order motion can be understood as follows. The particle tends to spiral around a field line, but the field line curves off to the side. As far as the motion of the guiding center is concerned, this is equivalent to a centrifugal acceleration of magnitude v_{\parallel}^2/R . This acceleration can be viewed as arising from an effective electric field,

$$\mathbf{E}_{\text{eff}} = \frac{\gamma m}{e} \frac{\mathbf{R}}{R^2} v_{\parallel}^2 \quad (12.56)$$

Fig. 12.4 (a) Particle moving in helical path along lines of uniform, constant magnetic induction. (b) Curvature of lines of magnetic induction will cause drift perpendicular to the (x, y) plane.

in addition to the magnetic induction \mathbf{B}_0 . From (12.43) we see that the combined effective electric field and the magnetic induction cause a *curvature drift velocity*,

$$\mathbf{v}_C \approx c \frac{\gamma m}{e} v_{\parallel}^2 \frac{\mathbf{R} \times \mathbf{B}_0}{R^2 B_0^2} \quad (12.57)$$

With the definition of $\omega_B = eB_0/\gamma mc$, the curvature drift can be written

$$\mathbf{v}_C = \frac{v_{\parallel}^2}{\omega_B R} \left(\frac{\mathbf{R} \times \mathbf{B}_0}{RB_0} \right) \quad (12.58)$$

The direction of drift is specified by the vector product, in which \mathbf{R} is the radius vector *from* the effective center of curvature *to* the position of the charge. The sign in (12.58) is appropriate for positive charges and is independent of the sign of v_{\parallel} . For negative particles the opposite sign arises from ω_B .

A more straightforward, although pedestrian, derivation of (12.58) can be given by solving the Lorentz force equation directly. If we use cylindrical coordinates (ρ, ϕ, z) appropriate to Fig. 12.4b with origin at the center of curvature, the magnetic induction has only a ϕ component, $B_{\phi} = B_0$. Then the force equation can be easily shown to give the three equations,

$$\begin{aligned} \ddot{\rho} - \rho \dot{\phi}^2 &= -\omega_B \dot{z} \\ \rho \ddot{\phi} + 2\dot{\rho} \dot{\phi} &= 0 \\ \ddot{z} &= \omega_B \dot{\rho} \end{aligned} \quad (12.59)$$

If the zero-order trajectory is a helix with radius a small compared to the radius of curvature R , then, to lowest order, $\dot{\phi} \approx v_{\parallel}/R$, while $\rho \approx R$. Thus the first equation of (12.59) yields an approximate result for \dot{z} :

$$\dot{z} \approx \frac{v_{\parallel}^2}{\omega_B R} \quad (12.60)$$

This is just the curvature drift given by (12.58).

For regions of space in which there are no currents the gradient drift \mathbf{v}_G (12.55) and the curvature drift \mathbf{v}_C (12.58) can be combined into one simple form. This follows from the fact that for a two-dimensional field such as shown in Fig. 12.4b $\nabla \times \mathbf{B} = 0$ implies

$$\frac{\nabla_{\perp} B}{B} = -\frac{\mathbf{R}}{R^2}$$

Evidently then, for a two-dimensional field, the sum of \mathbf{v}_G and \mathbf{v}_C is a total drift velocity,

$$\mathbf{v}_D = \frac{1}{\omega_B R} (v_{\parallel}^2 + \frac{1}{2} v_{\perp}^2) \left(\frac{\mathbf{R} \times \mathbf{B}}{RB} \right) \quad (12.61)$$

where $v_{\perp} = \omega_B a$ is the transverse velocity of gyration. For singly charged nonrelativistic particles in thermal equilibrium, the magnitude of the drift

velocity is

$$v_D(\text{cm/sec}) = \frac{172 \cdot T(^{\circ}\text{K})}{R(\text{m}) B(\text{gauss})} \quad (12.62)$$

The particle drifts implied by (12.61) are troublesome in certain types of thermonuclear machines designed to contain hot plasma. A possible configuration is a toroidal tube with a strong axial field supplied by solenoidal windings around the torus. With typical parameters of $R=1$ meter, $B=10^3$ gauss, particles in a 1-eV plasma ($T \approx 10^4$ °K) will have drift velocities $v_D \sim 1.8 \times 10^3$ cm/sec. This means that they will drift out to the walls in a small fraction of a second. For hotter plasmas the drift rate is correspondingly greater. One way to prevent this first-order drift in toroidal geometries is to twist the torus into a figure eight. Since the particles generally make many circuits around the closed path before drifting across the tube, they feel no net curvature or gradient of the field. Consequently they experience no net drift, at least to first order in $1/R$. This method of eliminating drifts due to spatial variations of the magnetic field is used in the Stellarator type of thermonuclear machine, in which containment is attempted with a strong, externally produced, axial magnetic field.

12.6 Adiabatic Invariance of Flux through Orbit of Particle

The various motions discussed in the previous sections have been perpendicular to the lines of magnetic force. These motions, caused by electric fields or by the gradient or curvature of the magnetic field, arise because of the peculiarities of the magnetic-force term in the Lorentz force equation. To complete our general survey of particle motion in magnetic fields we must consider motion parallel to the lines of force. It turns out that for slowly varying fields a powerful tool is the concept of adiabatic invariants. In celestial mechanics and in the old quantum theory adiabatic invariants were useful in discussing perturbations on the one hand, and in deciding what quantities were to be quantized on the other. Our discussion will resemble most closely the celestial mechanical problem, since we are interested in the behavior of a charged particle in slowly varying fields which can be viewed as small departures from the simple, uniform, static field considered in Section 12.3.

The concept of adiabatic invariance is introduced by considering the action integrals of a mechanical system. If q_i and p_i are the generalized canonical coordinates and momenta, then, for each coordinate which is periodic, the action integral J_i is defined by

$$J_i = \oint p_i dq_i \quad (12.63)$$

The integration is over a complete cycle of the coordinate q_i . For a given

mechanical system with specified initial conditions the action integrals J_i are constants. If now the properties of the system are changed in some way (e.g., a change in spring constant or mass of some particle), the question arises as to how the action integrals change. It can be proved* that, if the change in property is slow compared to the relevant periods of motion and is not related to the periods (such a change is called an *adiabatic change*), the action integrals are invariant. This means that, if we have a certain mechanical system in some state of motion and we make an adiabatic change in some property so that after a long time we end up with a different mechanical system, the final motion of that different system will be such that the action integrals have the same values as in the initial system. Clearly this provides a powerful tool in examining the effects of small changes in properties.

For a charged particle in a uniform, static, magnetic induction \mathbf{B} the transverse motion is periodic. The action integral for this transverse motion is

$$J = \oint \mathbf{P}_\perp \cdot d\mathbf{l} \quad (12.64)$$

where \mathbf{P}_\perp is the transverse component of the canonical momentum (12.11) and $d\mathbf{l}$ is a directed line element along the circular path of the particle. From (12.11) we find that

$$J = \oint \gamma m \mathbf{v}_\perp \cdot d\mathbf{l} + \frac{e}{c} \oint \mathbf{A} \cdot d\mathbf{l} \quad (12.65)$$

Since \mathbf{v}_\perp is parallel to $d\mathbf{l}$, we find

$$J = \oint \gamma m \omega_B a^2 d\theta + \frac{e}{c} \oint \mathbf{A} \cdot d\mathbf{l} \quad (12.66)$$

Applying Stokes's theorem to the second integral and integrating over θ in the first integral, we obtain

$$J = 2\pi \gamma m \omega_B a^2 + \frac{e}{c} \int_S \mathbf{B} \cdot \mathbf{n} da \quad (12.67)$$

Since the line element $d\mathbf{l}$ in (12.64) is in a counterclockwise sense relative to \mathbf{B} , the unit vector \mathbf{n} is antiparallel to \mathbf{B} . Hence the integral over the circular orbit subtracts from the first term. This gives

$$J = \gamma m \omega_B \pi a^2 = \frac{e}{c} (B \pi a^2) \quad (12.68)$$

making use of $\omega_B = eB/\gamma mc$. The quantity $B \pi a^2$ is the flux through the particle's orbit.

If the particle moves through regions where the magnetic field strength

* See, for example, M. Born, *The Mechanics of the Atom*, Bell, London (1927).

varies slowly in space or time, the adiabatic invariance of J means that the flux linked by the particle's orbit remains constant. If B increases, the radius a will decrease so that $B\pi a^2$ remains unchanged. This constancy of flux linked can be phrased in several ways involving the particle's orbit radius, its transverse momentum, its magnetic moment. These different statements take the forms:

$$\left. \begin{array}{l} Ba^2 \\ p_{\perp}^2/B \\ \gamma\mu \end{array} \right\} \text{ are adiabatic invariants} \quad (12.69)$$

where $\mu = (e\omega_B a^2/2c)$ is the magnetic moment of the current loop of the particle in orbit. If there are only static magnetic fields present, the speed of the particle is constant and its total energy does not change. Then the magnetic moment μ is itself an adiabatic invariant. In time-varying fields or with static electric fields, μ is an adiabatic invariant only in the nonrelativistic limit.

Let us now consider a simple situation in which a static magnetic field \mathbf{B} acts mainly in the z direction, but has a small positive gradient in that direction. Figure 12.5 shows the general behavior of the lines of force. In addition to the z component of field there is a small radial component due to the curvature of the lines of force. For simplicity we assume cylindrical symmetry. Suppose that a particle is spiraling around the z axis in an orbit of small radius with a transverse velocity $v_{\perp 0}$ and a component of velocity $v_{\parallel 0}$ parallel to \mathbf{B} at $z=0$, where the axial field strength is B_0 . The speed of the particle is constant so that any position along the z axis

$$v_{\parallel}^2 + v_{\perp}^2 = v_0^2 \quad (12.70)$$

where $v_0^2 = v_{\perp 0}^2 + v_{\parallel 0}^2$ is the square of the speed at $z=0$. If we assume that the flux linked is a constant of the motion, then (12.69) allows us to write

$$\frac{v_{\perp}^2}{B} = \frac{v_{\perp 0}^2}{B_0} \quad (12.71)$$

where B is the axial magnetic induction. Then we find the parallel velocity at any

Fig. 12.5

Fig. 12.6 Reflection of charged particle out of region of high field strength.

position along the z axis given by

$$v_{\parallel}^2 = v_0^2 - v_{\perp 0}^2 \frac{B(z)}{B_0} \quad (12.72)$$

Equation (12.72) for the velocity of the particle in the z direction is equivalent to the first integral of Newton's equation of motion for a particle in a one-dimensional potential*

$$V(z) = \frac{1}{2} m \frac{v_{\perp 0}^2}{B_0} B(z)$$

If $B(z)$ increases enough, eventually the right-hand side of (12.72) will vanish at some point $z = z_0$. This means that the particle spirals in an ever-tighter orbit along the lines of force, converting more and more translational energy into energy of rotation, until its axial velocity vanishes. Then it turns around, still spiraling in the same sense, and moves back in the negative z direction. The particle is reflected by the magnetic field, as is shown schematically in Fig. 12.6.

Equation (12.72) is a consequence of the assumption that p_{\perp}^2/B is invariant. To show that at least to first order this invariance follows directly from the Lorentz force equation, we consider an explicit solution of the equations of motion. If the magnetic induction along the axis is $B(z)$, there will be a radial component of the field near the axis given by the divergence equation as

$$B_{\rho}(\rho, z) \approx -\frac{1}{2} \rho \frac{\partial B(z)}{\partial z} \quad (12.73)$$

where ρ is the radius out from the axis. The z component of the force equation is

$$\ddot{z} = \frac{e}{\gamma mc} (-\rho \dot{\phi} B_{\rho}) \approx \frac{e}{2\gamma mc} \rho^2 \dot{\phi} \frac{\partial B(z)}{\partial z} \quad (12.74)$$

where $\dot{\phi}$ is the angular velocity around the z axis. This can be written, correct to

* Note, however, that our discussion is fully relativistic. The analogy with one-dimensional nonrelativistic mechanics is only a formal one.

first order in the small variation of $B(z)$, as

$$\ddot{z} \approx -\frac{v_{\perp 0}^2}{2B_0} \frac{\partial B(z)}{\partial z} \quad (12.75)$$

where we have used $\rho^2 \dot{\phi} \approx -(\alpha^2 \omega_B)_0 = -(v_{\perp 0}^2 / \omega_{B0})$. Equation (12.75) has as its first integral (12.72), showing that to first order in small quantities the constancy of flux linking the orbit follows directly from the equations of motion.

The adiabatic invariance of the flux linking an orbit is useful in discussing particle motions in all types of spatially varying magnetic fields. The simple example described above illustrates the principle of the “magnetic mirror”: charged particles are reflected by regions of strong magnetic field. This mirror property formed the basis of a theory of Fermi for the acceleration of cosmic-ray particles to very high energies in interstellar space by collisions with moving magnetic clouds. The mirror principle can be applied to the containment of a hot plasma for thermonuclear energy production. A magnetic bottle can be constructed with an axial field produced by solenoidal windings over some region of space, and additional coils at each end to provide a much higher field toward the ends. The lines of force might appear as shown in Fig. 12.7. Particles created or injected into the field in the central region will spiral along the axis, but will be reflected by the magnetic mirrors at each end. If the ratio of maximum field B_m in the mirror to the field B in the central region is very large, only particles with a very large component of velocity parallel to the axis can penetrate through the ends. From (12.72) it is evident that the criterion for trapping is

$$\left| \frac{v_{\parallel 0}}{v_{\perp 0}} \right| < \left(\frac{B_m}{B} - 1 \right)^{1/2} \quad (12.76)$$

If the particles are injected into the apparatus, it is easy to satisfy requirement (12.76). Then the escape of particles is governed by the rate at which they are scattered by residual gas atoms, etc., in such a way that their velocity components violate (12.76).

Fig. 12.7 Schematic diagram of “mirror” machine for the containment of a hot plasma.

Another area of application of these principles is to terrestrial and stellar magnetic fields. The motion of charged particles in the magnetic dipole fields of the sun or earth can be understood in terms of the adiabatic invariant discussed here and the drift velocities of Section 12.5. Some aspects of this topic are left to Problems 12.8 and 12.9 on the trapped particles around the earth (the Van Allen belts).

12.7 Lowest-Order Relativistic Corrections to the Lagrangian for Interacting Charged Particles, the Darwin Lagrangian

In Section 12.1 we discussed the general Lagrangian formalism for a relativistic particle in external electromagnetic fields described by the vector and scalar potentials, \mathbf{A} and Φ . The appropriate interaction Lagrangian was given by (12.8). If we now consider the problem of a conventional Lagrangian description of the interaction of two or more charged particles with each other, we see that it is possible only at nonrelativistic velocities. The Lagrangian is supposed to be a function of the instantaneous velocities and coordinates of all the particles. When the finite velocity of propagation of electromagnetic fields is taken into account, this is no longer possible, since the values of the potentials at one particle due to the other particles depend on their state of motion at “retarded” times. Only when retardation effects can be neglected is a Lagrangian description in terms of instantaneous positions and velocities possible. In view of this one might think that a Lagrangian could be formulated only in the static limit, i.e., to zeroth order in (v/c) . We will now show, however, that lowest-order relativistic corrections can be included, giving an approximate Lagrangian for interacting particles, correct to the order of $(v/c)^2$ inclusive.

It is sufficient to consider two interacting particles with charges q_1 and q_2 , masses m_1 and m_2 , and coordinates \mathbf{x}_1 and \mathbf{x}_2 . The relative separation is $\mathbf{r} = \mathbf{x}_1 - \mathbf{x}_2$. The interaction Lagrangian in the static limit is just the negative of the electrostatic potential energy,

$$L_{\text{int}}^{\text{NR}} = -\frac{q_1 q_2}{r} \quad (12.77)$$

If attention is directed to the first particle, this can be viewed as the negative of the product of q_1 and the scalar potential Φ_{12} due to the second particle at the position of the first. This is of the same form as (12.7). If we wish to generalize beyond the static limit, we must, according to (12.8), determine both Φ_{12} and \mathbf{A}_{12} , at least to some degree of approximation. In general there will be relativistic corrections to both Φ_{12} and \mathbf{A}_{12} . But in the *Coulomb gauge*, the scalar potential is given correctly to all orders in v/c by the instantaneous Coulomb potential. Thus, if we calculate in that gauge, the scalar-potential contribution Φ_{12} is already known. All that needs to be considered is the vector potential \mathbf{A}_{12} .

If only the lowest-order relativistic corrections are desired, retardation effects can be neglected in computing \mathbf{A}_{12} . The reason is that the vector potential enters the Lagrangian (12.8) in the combination $q_1(\mathbf{v}_1/c) \cdot \mathbf{A}_{12}$. Since \mathbf{A}_{12} itself is of the order of v_2/c , greater accuracy in calculating \mathbf{A}_{12} is unnecessary. Consequently, we have the magnetostatic expression,

$$\mathbf{A}_{12} \approx \frac{1}{c} \int \frac{\mathbf{J}_t(\mathbf{x}') d^3 x'}{|\mathbf{x}_1 - \mathbf{x}'|} \quad (12.78)$$

where \mathbf{J}_t is the transverse part of the current due to the second particle, as discussed in Section 6.5. From equations (6.46)–(6.50) it can be shown that the transverse current is

$$\mathbf{J}_t(\mathbf{x}') = q_2 \mathbf{v}_2 \delta(\mathbf{x}' - \mathbf{x}_2) - \frac{q_2}{4\pi} \nabla' \left(\frac{\mathbf{v}_2 \cdot (\mathbf{x}' - \mathbf{x}_2)}{|\mathbf{x}' - \mathbf{x}_2|^3} \right) \quad (12.79)$$

When this is inserted in (12.78), the first term can be integrated immediately. Thus

$$\mathbf{A}_{12} \approx \frac{q_2 \mathbf{v}_2}{cr} - \frac{q_2}{4\pi c} \int \frac{1}{|\mathbf{x}' - \mathbf{x}_1|} \nabla' \left(\frac{\mathbf{v}_2 \cdot (\mathbf{x}' - \mathbf{x}_2)}{|\mathbf{x}' - \mathbf{x}_2|^3} \right) d^3 x'$$

By changing variables to $\mathbf{y} = \mathbf{x}' - \mathbf{x}_2$ and integrating by parts, the integral can be put in the form,

$$\mathbf{A}_{12} \approx \frac{q_2 \mathbf{v}_2}{cr} - \frac{q_2}{4\pi c} \nabla_r \int \frac{\mathbf{v}_2 \cdot \mathbf{y}}{y^3} \frac{1}{|\mathbf{y} - \mathbf{r}|} d^3 y$$

The integral can now be done in a straightforward manner to yield

$$\mathbf{A}_{12} \approx \frac{q_2}{c} \left[\frac{\mathbf{v}_2}{r} - \frac{1}{2} \nabla_r \left(\frac{\mathbf{v}_2 \cdot \mathbf{r}}{r} \right) \right]$$

The differentiation of the second term leads to the final result

$$\mathbf{A}_{12} \approx \frac{q_2}{2cr} \left[\mathbf{v}_2 + \frac{\mathbf{r}(\mathbf{v}_2 \cdot \mathbf{r})}{r^2} \right] \quad (12.80)$$

With expression (12.80) for the vector potential due to the second particle at the position of the first, the interaction Lagrangian for two charged particles, including lowest-order relativistic effects, is

$$L_{\text{int}} = \frac{q_1 q_2}{r} \left\{ -1 + \frac{1}{2c^2} \left[\mathbf{v}_1 \cdot \mathbf{v}_2 + \frac{(\mathbf{v}_1 \cdot \mathbf{r})(\mathbf{v}_2 \cdot \mathbf{r})}{r^2} \right] \right\} \quad (12.81)$$

This interaction form was first obtained by Darwin in 1920. It is of importance in a quantum-mechanical discussion of relativistic corrections in two-electron atoms. In the quantum-mechanical problem the velocity vectors are replaced by their corresponding quantum-mechanical operators (Dirac α 's). Then the interaction is known as the Breit interaction (1930).*

* See H. A. Bethe and E. E. Salpeter, *Quantum Mechanics of One- and Two-Electron Atoms*, Springer-Verlag, Berlin, Academic, New York, 1957, pp. 170 ff.

For a system of interacting charged particles the complete Darwin Lagrangian, correct to order $1/c^2$ inclusive, can be written down by expanding the free-particle Lagrangian (12.6) for each particle and summing up all the interaction terms of the form (12.81). The result is

$$L_{\text{Darwin}} = \frac{1}{2} \sum_i m_i v_i^2 + \frac{1}{8c^2} \sum_i m_i v_i^4 - \frac{1}{2} \sum'_{i,j} \frac{q_i q_j}{r_{ij}} + \frac{1}{4c^2} \sum'_{i,j} \frac{q_i q_j}{r_{ij}} [\mathbf{v}_i \cdot \mathbf{v}_j + (\mathbf{v}_i \cdot \hat{\mathbf{r}}_{ij})(\mathbf{v}_j \cdot \hat{\mathbf{r}}_{ij})] \quad (12.82)$$

where $r_{ij} = |\mathbf{x}_i - \mathbf{x}_j|$, $\hat{\mathbf{r}}_{ij}$ is a unit vector in the direction $\mathbf{x}_i - \mathbf{x}_j$, and the prime on the double summation indicates the omission of the (self-energy) terms, $i = j$. Although the Darwin Lagrangian has had its most celebrated application in the quantum-mechanical context of the Breit interaction, it has uses in the purely classical domain. Two examples are cited in the suggested reading at the end of the chapter. See also the problems.

12.8 Lagrangian for the Electromagnetic Field

In Section 12.1 we considered the Lagrangian formulation of the equations of motion of a charged particle in an external electromagnetic field. We now examine a Lagrangian description of the electromagnetic field in interaction with specified external sources of charge and current. The Lagrangian approach to continuous fields closely parallels the techniques used for discrete point particles.* The finite number of coordinates $q_i(t)$ and $\dot{q}_i(t)$, $i = 1, 2, \dots, n$, are replaced by an infinite number of degrees of freedom. Each point in space-time x^α corresponds to a finite number of values of the discrete index i . The generalized coordinate q_i is replaced by a continuous field $\phi_k(x)$, with a discrete index ($k = 1, 2, \dots, n$) and a continuous index (x^α). The generalized velocity \dot{q}_i is replaced by the 4-vector gradient, $\partial^\beta \phi_k$. The Euler-Lagrange equations follow from the stationary property of the action integral with respect to variations $\delta\phi_k$ and $\delta(\partial^\beta \phi_k)$ around the physical values. We thus have the following correspondences:

$$\begin{aligned} i &\rightarrow x^\alpha, k \\ q_i &\rightarrow \phi_k(x) \\ \dot{q}_i &\rightarrow \partial^\alpha \phi_k(x) \\ L = \sum_i L_i(q_i, \dot{q}_i) &\rightarrow \int \mathcal{L}(\phi_k, \partial^\alpha \phi_k) d^3x \\ \frac{d}{dt} \left(\frac{\partial L}{\partial \dot{q}_i} \right) &= \frac{\partial L}{\partial q_i} \rightarrow \partial^\beta \frac{\partial \mathcal{L}}{\partial (\partial^\beta \phi_k)} = \frac{\partial \mathcal{L}}{\partial \phi_k} \end{aligned} \quad (12.83)$$

* For more detail and or background than given in our abbreviated account, see Goldstein, Chapter 11 and Wentzel, Chapter 1, or other references cited at the end of the chapter.

where \mathcal{L} is a Lagrangian *density*, corresponding to a definite point in space-time and equivalent to the individual terms in a discrete particle Lagrangian like (12.82). For the electromagnetic field the “coordinates” and “velocities” are A^α and $\partial^\beta A^\alpha$.

The action integral takes the form,

$$A = \iint \mathcal{L} d^3x dt = \int \mathcal{L} d^4x \quad (12.84)$$

The Lorentz-invariant nature of the action is preserved provided the *Lagrangian density* \mathcal{L} is a *Lorentz scalar* (because the 4-dimensional volume element is invariant). In analogy with the situation with discrete particles we expect the free-field Lagrangian at least to be quadratic in the velocities, that is, $\partial^\beta A^\alpha$ or $F^{\alpha\beta}$. The only Lorentz invariant quadratic forms are $F_{\alpha\beta}F^{\alpha\beta}$ and $F_{\alpha\beta}\mathcal{F}^{\alpha\beta}$ (see Problem 11.12). The latter is a scalar under proper Lorentz transformations, but a pseudoscalar under inversion. If we demand a scalar \mathcal{L} under inversions as well as proper Lorentz transformations, we must have $\mathcal{L}_{\text{free}}$ as some multiple of $F_{\alpha\beta}F^{\alpha\beta}$. The interaction term in \mathcal{L} involves the source densities. These are described by the current density 4-vector, $J^\alpha(x)$. From the form of the electrostatic and magnetostatic energies, or from the charged-particle interaction Lagrangian (12.8), we anticipate that \mathcal{L}_{int} is a multiple of $J_\alpha A^\alpha$. With this motivation we postulate the electromagnetic Lagrangian density:

$$\mathcal{L} = -\frac{1}{16\pi} F_{\alpha\beta}F^{\alpha\beta} - \frac{1}{c} J_\alpha A^\alpha \quad (12.85)$$

The coefficient and sign of the interaction terms is chosen to agree with (12.8); the sign and scale of the free Lagrangian is set by the definitions of the field strengths and the Maxwell equations.

In order to use the Euler-Lagrange equation in the form given in (12.83), we substitute the definition of the fields and write

$$\mathcal{L} = -\frac{1}{16\pi} g_{\lambda\mu} g_{\nu\sigma} (\partial^\mu A^\sigma - \partial^\sigma A^\mu) (\partial^\lambda A^\nu - \partial^\nu A^\lambda) - \frac{1}{c} J_\alpha A^\alpha \quad (12.86)$$

In calculating $\partial\mathcal{L}/\partial(\partial^\beta A^\alpha)$ care must be taken to pick up all the terms. There are four different terms, as can be seen from the following explicit calculation:

$$\frac{\partial\mathcal{L}}{\partial(\partial^\beta A^\alpha)} = -\frac{1}{16\pi} g_{\lambda\mu} g_{\nu\sigma} \left\{ \delta_\beta^\mu \delta_\alpha^\sigma F^{\lambda\nu} - \delta_\beta^\sigma \delta_\alpha^\mu F^{\lambda\nu} \right. \\ \left. + \delta_\beta^\lambda \delta_\alpha^\nu F^{\mu\sigma} - \delta_\beta^\nu \delta_\alpha^\lambda F^{\mu\sigma} \right\}$$

Because of the symmetry of $g_{\alpha\beta}$ and the antisymmetry of $F^{\alpha\beta}$, all four terms are equal and the derivative becomes

$$\frac{\partial\mathcal{L}}{\partial(\partial^\beta A^\alpha)} = -\frac{1}{4\pi} F_{\beta\alpha} = \frac{1}{4\pi} F_{\alpha\beta} \quad (12.87)$$

The other part of the Euler-Lagrange equation is

$$\frac{\partial \mathcal{L}}{\partial A^\alpha} = -\frac{1}{c} J_\alpha \quad (12.88)$$

Thus the equations of motion of the electromagnetic field are

$$\frac{1}{4\pi} \partial^\beta F_{\beta\alpha} = \frac{1}{c} J_\alpha \quad (12.89)$$

These are recognized as a covariant form of the inhomogeneous Maxwell equations (11.141).

The Lagrangian (12.85) yields the inhomogeneous Maxwell equations, but not the homogeneous ones. This is because the definition of the field strength tensor $F^{\alpha\beta}$ in terms of the 4-vector potential A^λ was chosen so that the homogeneous equations were satisfied automatically (see Section 6.4). To see this in our present 4-tensor notation, consider the left-hand side of the homogeneous equations (11.142):

$$\begin{aligned} \partial_\alpha \mathcal{F}^{\alpha\beta} &= \frac{1}{2} \partial_\alpha \epsilon^{\alpha\beta\lambda\mu} F_{\lambda\mu} \\ &= \partial_\alpha \epsilon^{\alpha\beta\lambda\mu} \partial_\lambda A_\mu \\ &= \epsilon^{\alpha\beta\lambda\mu} \partial_\alpha \partial_\lambda A_\mu \end{aligned}$$

But the differential operator $\partial_\alpha \partial_\lambda$ is symmetric in α and λ (assuming A_μ is well-behaved), while $\epsilon^{\alpha\beta\lambda\mu}$ is antisymmetric in α and λ . Thus the contraction on α and λ vanishes. The homogenous Maxwell equations are satisfied trivially.

The conservation of the source current density can be obtained from (12.89) by taking the 4-divergence of both sides:

$$\frac{1}{4\pi} \partial^\alpha \partial^\beta F_{\beta\alpha} = \frac{1}{c} \partial^\alpha J_\alpha$$

The left-hand side has a differential operator that is symmetric in α and β , while $F_{\beta\alpha}$ is antisymmetric. Again the contraction vanishes and we have

$$\partial^\alpha J_\alpha = 0 \quad (12.90)$$

12.9 Proca Lagrangian, Photon Mass Effects

The conventional Maxwell equations and the Lagrangian (12.85) are based on the hypothesis that the photon has zero mass. As discussed in the Introduction, it can always be asked what evidence there is for the masslessness of the photon or equivalently for the inverse square law of the Coulomb force and what consequences would stem from a nonvanishing mass. A systematic technique for such considerations is the Lagrangian formulation. We modify the Lagrangian density (12.85) by adding a “mass” term. The resulting Lagrangian is known as

the Proca Lagrangian, Proca having been the first to consider it (1930, 1936). The *Proca Lagrangian* is

$$\mathcal{L}_{\text{Proca}} = -\frac{1}{16\pi} F_{\alpha\beta} F^{\alpha\beta} + \frac{\mu^2}{8\pi} A_\alpha A^\alpha - \frac{1}{c} J_\alpha A^\alpha \quad (12.91)$$

The parameter μ has dimensions of inverse length and is the reciprocal Compton wavelength of the photon ($\mu = m_\gamma c/\hbar$). Instead of (12.89), the Proca equations of motion are

$$\partial^\beta F_{\beta\alpha} + \mu^2 A_\alpha = \frac{4\pi}{c} J_\alpha \quad (12.92)$$

We observe that in the Proca equations the potentials as well as the fields enter. In contrast to the Maxwell equations, the potentials acquire real physical (observable) significance through the mass term. In the Lorentz gauge, now required by current conservation, Eq. (12.92) can be written

$$\square A_\alpha + \mu^2 A_\alpha = \frac{4\pi}{c} J_\alpha \quad (12.93)$$

and in the static limit takes the form,

$$\nabla^2 A_\alpha - \mu^2 A_\alpha = -\frac{4\pi}{c} J_\alpha$$

If the source is a point charge q at rest at the origin, only the time-component $A_0 = \Phi$ is nonvanishing. It takes the spherically symmetric Yukawa form,

$$\Phi(x) = q \frac{e^{-\mu r}}{r} \quad (12.94)$$

This shows the characteristic feature of the photon mass. There is an exponential fall-off of the static potentials and fields, with the $1/e$ distance equal to μ^{-1} . As discussed in the Introduction and also in Problem 12.14, the exponential factor alters the character of the earth's magnetic field sufficiently that we can set quite stringent limits on the photon mass from geomagnetic data. It was at one time suggested* that relatively simple laboratory experiments using lumped LC circuits could improve on even these limits, but the idea was conceptually flawed. There is enough subtlety involved that the subject is worth a brief discussion.†

The starting point of the argument is (12.93) in the absence of sources. If we assume harmonic time and space variation, the constraint equation on the

* P. A. Franken and G. W. Ampulski, *Phys. Rev. Letters* **26**, 115 (1971).

† Shortly after the idea was proposed, several analyses based on the Proca equations appeared. Some of these are A. S. Goldhaber and M. M. Nieto, *Phys. Rev. Letters* **26**, 1390 (1971); D. Park and E. R. Williams, *Phys. Rev. Letters* **26**, 1393 (1971); N. M. Kroll, *Phys. Rev. Letters* **26**, 1395 (1971); D. G. Boulware, *Phys. Rev. Letters* **27**, 55 (1971); N. M. Kroll, *Phys. Rev. Letters* **27**, 340 (1971).

frequency and wave number is

$$\omega^2 = c^2 k^2 + \mu^2 c^2 \quad (12.95)$$

This is the standard expression for the square of the energy (divided by \hbar) for a particle of momentum $\hbar k$ and mass $\mu \hbar/c$. Now consider some resonant system (cavity or lumped circuit). Suppose that when $\mu = 0$ its resonant frequency is ω_0 , while for $\mu \neq 0$ the resonant frequency is ω . From the structure of (12.95) it is tempting to write the relation,

$$\omega^2 = \omega_0^2 + \mu^2 c^2 \quad (12.96)$$

Evidently, the smaller the frequency, the larger the fractional difference between ω and ω_0 for a given photon mass. This suggests an experiment with lumped *LC* circuits. The scheme would be to measure the resonant frequencies of a sequence of circuits whose ω_0^2 values are in known ratios. If the observed resonant frequencies are not in the same proportion, evidence for $\mu \neq 0$ in (12.96) would be found. Franken and Ampulski compared two circuits, one with a certain inductance L and a capacitance C and hence with $\omega_0^2 = (LC)^{-1}$, and another with the same inductor, but two capacitances C in parallel. The squares of the observed frequencies, corrected for resistive effects, were in the ratio 2:1 within errors. They thus inferred an upper limit on the photon mass, pointing out that in principle improvement of the accuracy by several orders of magnitude was possible if the idea was sound.

What is wrong with the idea? The first observation is that *lumped* circuits are by definition incapable of setting *any* limit on the photon mass.* The lumped circuit concept of a capacitance is a two-terminal box with the property that the current flow I at one terminal and the voltage V between the terminals are related by $I = C dV/dt$. Similarly a lumped inductance is a two-terminal box with the governing equation, $V = -L dI/dt$. When two such boxes are connected together, the currents and voltages are necessarily equal and the combined system is described by the equation, $V + LC d^2 V/dt^2 = 0$. The resonant frequency of a lumped *LC* circuit is $\omega_0 = (LC)^{-1/2}$, period.

It is true, of course, that a given set of conducting surfaces or a given coil of wire will have different static properties of capacitance or inductance depending on whether $\mu = 0$ or not. The potentials and fields are all modified by exponential factors of the general form of (12.94). The question then arises as to whether one can set a meaningful limit on μ by means of a "table-top" experiment, that is, an experiment not with lumped circuit elements but with ones whose sizes are modest. The reader can verify, for example, that for a solid conducting sphere of radius a at the center of a hollow conducting shell of inner radius b held at zero

* I am indebted to E. M. Purcell for emphasizing that this is the point almost universally missed or at least glossed over in discussions of the Franken-Ampulski proposal.

potential, the capacitance is increased by an amount $\mu^2 a^2 b/3$, provided $\mu b \ll 1$. It then turns out that instead of the fractional difference,

$$\frac{\Delta\omega}{\omega_0} \approx \frac{\mu^2 c^2}{2\omega_0^2} \quad (12.97)$$

that follows from (12.96) with $\omega_0^2 = (LC)^{-1}$, the actual effect of the finite photon mass is

$$\frac{\Delta\omega}{\omega_0} = 0(\mu^2 d^2) \quad (12.98)$$

where d is a dimension characteristic of the circuit and ω_0 is the resonant frequency for $\mu = 0$. This makes a “table-top” experiment possible in principle, but very insensitive in practice to a possible photon mass.

Although the estimate (12.98) says it all, it is of interest to consider the effect of a finite photon mass for transmission lines, wave guides, or resonant cavities. For transmission lines, the effect of the photon mass is the same as for static lumped circuit parameters. We recall from Chapter 8 that for $\mu = 0$ the TEM modes of a transmission line are degenerate modes, with propagation at a phase velocity equal to the velocity of light. The situation does not alter if $\mu \neq 0$. The only difference is that the *transverse* behavior of the fields is governed by $(\nabla_t^2 - \mu^2)\psi = 0$ instead of the Laplace equation. The capacitance and inductance per unit length of the transmission line are altered by fractional amounts of order $\mu^2 d^2$, but nothing else. (The result of Problem 6.5 still holds.)

For TE and TM modes in a wave guide the situation is more complicated. The boundary conditions on fields and potentials must be considered with care. Analysis shows (see Kroll, *op. cit.*) that TM modes have propagation governed by the naive equation (12.96), but that TE modes generally propagate differently. In any event, since the cutoff frequency of a guide is determined by its lateral dimensions, the generally incorrect estimate (12.97) becomes the same as the proper estimate (12.98).

For resonant cavities a rigorous solution is complicated, but for small mass some simple results emerge. For example, for a rectangular cavity, (12.96) holds to a good approximation for modes with l, m, n all different from zero, but fails if any mode number is zero. This is because the fields behave in the direction associated with vanishing l, m , or n as static fields and the arguments already made apply. The low frequency modes (Schumann resonances) of the earth-ionosphere cavity, discussed in Section 8.9, are of particular interest. These modes have a radial electric field and to the *zeroth order* in h/R , where h is the height of the ionosphere and R the radius of the earth, are TEM modes in a parallel plate geometry. Thus their propagation and hence resonant frequencies are unaltered from their $\mu = 0$ values. To *first order* in h/R there is a mass-dependent change in resonant frequency. The result (see Kroll's second paper cited above) is that (12.97) is modified on its right-hand side by a multiplicative

factor $g \approx 0.44 h/R$ for the lowest Schumann mode. With $h \approx 70$ km, $g \approx 5 \times 10^{-3}$. This means that the resonant frequency of $\omega_0 \approx 50 \text{ sec}^{-1}$ is a factor of $(1/g)^{1/2} \approx 14$ less effective in setting a limit on the photon mass than naive considerations imply.

12.10 Canonical and Symmetric Stress Tensors, Conservation Laws

(a) Generalization of the Hamiltonian: Canonical Stress Tensor

In particle mechanics the transition to the Hamiltonian formulation and conservation of energy is made by first defining the canonical momentum variables,

$$p_i = \frac{\partial L}{\partial \dot{q}_i} \quad (12.99)$$

and then introducing the Hamiltonian,

$$H = \sum_i p_i \dot{q}_i - L \quad (12.100)$$

It can then be shown that $dH/dt = 0$ provided $\partial L/\partial t = 0$. For fields we anticipate having a Hamiltonian density whose volume integral over three-dimensional space is the Hamiltonian. The Lorentz transformation properties of \mathcal{H} can be guessed as follows. Since the energy of a particle is the time component of a 4-vector, the Hamiltonian should transform in the same way. Since $H = \int \mathcal{H} d^3x$, and the invariant 4-volume element is $d^4x = d^3x dx_0$, it is necessary that the Hamiltonian density \mathcal{H} transform as the time-time component of a second rank tensor. If the Lagrangian density for some fields is a function of the field variables $\phi_k(x)$, $\partial^\alpha \phi_k(x)$, $k = 1, 2, \dots, n$, the Hamiltonian density is defined in analogy with (12.100) as

$$\mathcal{H} = \sum_k \frac{\partial \mathcal{L}}{\partial \left(\frac{\partial \phi_k}{\partial t} \right)} \frac{\partial \phi_k}{\partial t} - \mathcal{L} \quad (12.101)$$

The first factor in the sum is the field momentum canonically conjugate to $\phi_k(x)$ and $\partial \phi_k / \partial t$ is equivalent to the velocity \dot{q}_i . The inferred Lorentz transformation properties of \mathcal{H} suggest that the *covariant generalization of the Hamiltonian density* is the *canonical stress tensor*:

$$T^{\alpha\beta} = \sum_k \frac{\partial \mathcal{L}}{\partial (\partial_\alpha \phi_k)} \partial^\beta \phi_k - g^{\alpha\beta} \mathcal{L} \quad (12.102)$$

For the free electromagnetic field Lagrangian,

$$\mathcal{L}_{em} = -\frac{1}{16\pi} F_{\mu\nu} F^{\mu\nu} \quad (12.103)$$

the canonical stress tensor is

$$T^{\alpha\beta} = \frac{\partial \mathcal{L}_{em}}{\partial (\partial_\alpha A^\lambda)} \partial^\beta A^\lambda - g^{\alpha\beta} \mathcal{L}_{em}$$

where a summation over λ is implied by the repeated index. With the help of (12.87) (but notice the placing of the indices!) we find

$$T^{\alpha\beta} = -\frac{1}{4\pi} g^{\alpha\mu} F_{\mu\lambda} \partial^\beta A^\lambda - g^{\alpha\beta} \mathcal{L}_{em} \quad (12.104)$$

To elucidate the meaning of the tensor we exhibit some components. With $\mathcal{L} = (\mathbf{E}^2 - \mathbf{B}^2)/8\pi$ and (11.138) we find

$$\left. \begin{aligned} T^{00} &= \frac{1}{8\pi} (\mathbf{E}^2 + \mathbf{B}^2) + \frac{1}{4\pi} \nabla \cdot (\Phi \mathbf{E}) \\ T^{0i} &= \frac{1}{4\pi} (\mathbf{E} \times \mathbf{B})_i + \frac{1}{4\pi} \nabla \cdot (A_i \mathbf{E}) \\ T^{i0} &= \frac{1}{4\pi} (\mathbf{E} \times \mathbf{B})_i + \frac{1}{4\pi} \left[(\nabla \times \Phi \mathbf{B})_i - \frac{\partial}{\partial x_0} (\Phi E_i) \right] \end{aligned} \right\} \quad (12.105)$$

In writing the second terms here we have made use of the free-field equations $\nabla \cdot \mathbf{E} = 0$ and $\nabla \times \mathbf{B} - \partial \mathbf{E} / \partial x_0 = 0$. If we suppose that the fields are localized in some finite region of space (and, because of the finite velocity of propagation, they always are), the integrals over all 3-space at fixed time in some inertial frame of the components T^{00} and T^{0i} can be interpreted, as in Chapter 6, as the total energy and c times the total momentum of the electromagnetic fields in that frame:

$$\begin{aligned} \int T^{00} d^3x &= \frac{1}{8\pi} \int (\mathbf{E}^2 + \mathbf{B}^2) d^3x = E_{\text{field}} \\ \int T^{0i} d^3x &= \frac{1}{4\pi} \int (\mathbf{E} \times \mathbf{B})_i d^3x = cP_{\text{field}}^i \end{aligned} \quad (12.106)$$

These are the usual expressions for the total energy and momentum of the fields, discussed in Section 6.8. We note that the components T^{00} and T^{0i} themselves differ from the standard definitions of energy density and momentum density by added divergences. Upon integration over all space, however, the added terms give no contribution, being transformed into surface integrals at infinity where all the fields and potentials are identically zero.

The connection of the time-time and time-space components of $T^{\alpha\beta}$ with the field energy and momentum densities suggests that there is a covariant generalization of the differential conservation law (6.108) of Poynting's theorem. This differential conservation statement is

$$\partial_\alpha T^{\alpha\beta} = 0 \quad (12.107)$$

In proving (12.107) we treat the general situation described by the tensor (12.102) and the Euler-Lagrange equations (12.83). Consider

$$\begin{aligned}\partial_\alpha T^{\alpha\beta} &= \sum_k \partial_\alpha \left[\frac{\partial \mathcal{L}}{\partial (\partial_\alpha \phi_k)} \partial^\beta \phi_k \right] - \partial^\beta \mathcal{L} \\ &= \sum_k \left[\partial_\alpha \frac{\partial \mathcal{L}}{\partial (\partial_\alpha \phi_k)} \cdot \partial^\beta \phi_k + \frac{\partial \mathcal{L}}{\partial (\partial_\alpha \phi_k)} \partial_\alpha \partial^\beta \phi_k \right] - \partial^\beta \mathcal{L}\end{aligned}$$

By means of the equations of motion (12.83) the first term can be transformed so that

$$\partial_\alpha T^{\alpha\beta} = \sum_k \left[\frac{\partial \mathcal{L}}{\partial \phi_k} \partial^\beta \phi_k + \frac{\partial \mathcal{L}}{\partial (\partial_\alpha \phi_k)} \partial^\beta (\partial_\alpha \phi_k) \right] - \partial^\beta \mathcal{L}$$

Since $\mathcal{L} = \mathcal{L}(\phi_k, \partial^\alpha \phi_k)$, the square bracket, summed, is the expression for an implicit differentiation (chain rule). Hence

$$\partial_\alpha T^{\alpha\beta} = \partial^\beta \mathcal{L}(\phi_k, \partial^\alpha \phi_k) - \partial^\beta \mathcal{L} = 0$$

The conservation law or continuity equation (12.107) yields the conservation of total energy and momentum upon integration over all of 3-space at fixed time. Explicitly, we have

$$0 = \int \partial_\alpha T^{\alpha\beta} d^3x = \partial_0 \int T^{0\beta} d^3x + \int \partial_i T^{i\beta} d^3x$$

If the fields are localized the second integral (a divergence) gives no contribution. Then with the identifications (12.106) we find

$$\frac{d}{dt} E_{\text{field}} = 0, \quad \frac{d}{dt} \mathbf{P}_{\text{field}} = 0 \quad (12.108)$$

In this derivation of the conservation of energy (Poynting's theorem) and momentum and in the definitions (12.106) we have not exhibited manifest covariance. The results are valid for an observer at rest in the frame in which the fields are specified. But the question of transforming from one frame to another has not been addressed. With a covariant differential conservation law, $\partial_\alpha T^{\alpha\beta} = 0$, one expects that a covariant integral statement is also possible. The integrals in (12.106) do not appear to have the transformation properties of the components of a 4-vector. For sourcefree fields they do in fact transform properly (see Problem 12.15 and *Rohrlich*, Appendix A1-5), but in general do not. To avoid having electromagnetic energy and momentum defined separately in each inertial frame, without the customary connection between frames, it is necessary to construct explicitly covariant integral expressions for the electromagnetic energy and momentum, of which the forms (12.106) are special cases, valid in only one reference frame. This is discussed further in Chapter 17 in the context

of the classical electromagnetic self-energy problem. See *Rohrlich*, Section 4-9, for an explicitly covariant treatment of the conservation laws in integral form.

(b) *Symmetric Stress Tensor*

The canonical stress tensor $T^{\alpha\beta}$, while adequate so far, has a certain number of deficiencies. We have already seen that T^{00} and T^{0i} differ from the usual expressions for energy and momentum densities. Another drawback is its lack of symmetry—see T^{0i} and T^{i0} in (12.105). The question of symmetry arises when we consider the angular momentum of the field,

$$\mathbf{L}_{\text{field}} = \frac{1}{4\pi c} \int \mathbf{x} \times (\mathbf{E} \times \mathbf{B}) d^3x$$

The angular momentum density has a covariant generalization in terms of the third-rank tensor,

$$M^{\alpha\beta\gamma} = T^{\alpha\beta}x^\gamma - T^{\alpha\gamma}x^\beta \quad (12.109)$$

Then, just as (12.107) implies (12.108), so the vanishing of the 4-divergence,

$$\partial_\alpha M^{\alpha\beta\gamma} = 0 \quad (12.110)$$

implies conservation of the total angular momentum of the field. Direct calculation of (12.110) gives

$$0 = (\partial_\alpha T^{\alpha\beta})x^\gamma + T^{\gamma\beta} - (\partial_\alpha T^{\alpha\gamma})x^\beta - T^{\beta\gamma}$$

With (12.107) eliminating the first and third terms, we see that conservation of angular momentum requires that $T^{\alpha\beta}$ be symmetric. Two final criticisms of $T^{\alpha\beta}$, (12.104), are that it involves the potentials explicitly and so is not gauge-invariant, and that its trace (T^α_α) is not zero, as required for zero-mass photons.

There is a general procedure for constructing a symmetric, traceless, gauge-invariant stress tensor $\Theta^{\alpha\beta}$ from the canonical stress tensor $T^{\alpha\beta}$ (see the references at the end of the chapter). For the electromagnetic $T^{\alpha\beta}$ of (12.104) we proceed directly. We substitute $\partial^\beta A^\lambda = -F^{\lambda\beta} + \partial^\lambda A^\beta$ and obtain

$$T^{\alpha\beta} = \frac{1}{4\pi} \left[g^{\alpha\mu} F_{\mu\lambda} F^{\lambda\beta} + \frac{1}{4} g^{\alpha\beta} F_{\mu\nu} F^{\mu\nu} \right] - \frac{1}{4\pi} g^{\alpha\mu} F_{\mu\lambda} \partial^\lambda A^\beta \quad (12.111)$$

The first terms in (12.111) are symmetric in α and β and gauge invariant. With the help of the sourcefree Maxwell equations, the last term can be written

$$\begin{aligned} T_D^{\alpha\beta} &\equiv -\frac{1}{4\pi} g^{\alpha\mu} F_{\mu\lambda} \partial^\lambda A^\beta = \frac{1}{4\pi} F^{\lambda\alpha} \partial_\lambda A^\beta \\ &= \frac{1}{4\pi} (F^{\lambda\alpha} \partial_\lambda A^\beta + A^\beta \partial_\lambda F^{\lambda\alpha}) \\ &= \frac{1}{4\pi} \partial_\lambda (F^{\lambda\alpha} A^\beta) \end{aligned} \quad (12.112)$$

The tensor $T_D^{\alpha\beta}$ has the following easily verified properties:

$$(i) \quad \partial_\alpha T_D^{\alpha\beta} = 0$$

$$(ii) \quad \int T_D^{0\beta} d^3x = 0$$

Thus the differential conservation law (12.107) will hold for the difference $(T^{\alpha\beta} - T_D^{\alpha\beta})$ if it holds for $T^{\alpha\beta}$. Furthermore, the integral relations (12.106) for the total energy and momentum of the fields will also be valid in terms of the difference tensor. We are therefore free to *define the symmetric stress tensor* $\Theta^{\alpha\beta}$:

$$\Theta^{\alpha\beta} = T^{\alpha\beta} - T_D^{\alpha\beta}$$

or

$$\Theta^{\alpha\beta} = \frac{1}{4\pi} \left(g^{\alpha\mu} F_{\mu\lambda} F^{\lambda\beta} + \frac{1}{4} g^{\alpha\beta} F_{\mu\lambda} F^{\mu\lambda} \right) \quad (12.113)$$

Explicit calculation gives the following components,

$$\begin{aligned} \Theta^{00} &= \frac{1}{8\pi} (E^2 + B^2) \\ \Theta^{0i} &= \frac{1}{4\pi} (\mathbf{E} \times \mathbf{B})_i \\ \Theta^{ij} &= \frac{-1}{4\pi} \left[E_i E_j + B_i B_j - \frac{1}{2} \delta_{ij} (E^2 + B^2) \right] \end{aligned} \quad (12.114)$$

The indices i and j refer to Cartesian components in 3-space. The tensor $\Theta^{\alpha\beta}$ can be written in schematic matrix form as

$$\Theta^{\alpha\beta} = \begin{pmatrix} u & c\mathbf{g} \\ c\mathbf{g} & -T_{ij}^{(M)} \end{pmatrix} \quad (12.115)$$

In (12.115) the time-time and time-space components are expressed as the energy and momentum densities (6.106) and (6.118), while the space-space components (12.114) are seen to be just the negative of the Maxwell stress tensor (6.120), denoted here by $T_{ij}^{(M)}$ to avoid confusion with the canonical tensor $T^{\alpha\beta}$. The various other, covariant and mixed, forms of the stress tensor are

$$\begin{aligned} \Theta_{\alpha\beta} &= \begin{pmatrix} u & -c\mathbf{g} \\ -c\mathbf{g} & -T_{ij}^{(M)} \end{pmatrix} & \Theta^\alpha_\beta &= \begin{pmatrix} u & -c\mathbf{g} \\ c\mathbf{g} & T_{ij}^{(M)} \end{pmatrix} \\ \Theta_\alpha^\beta &= \begin{pmatrix} u & c\mathbf{g} \\ -c\mathbf{g} & T_{ij}^{(M)} \end{pmatrix} \end{aligned}$$

The differential conservation law,

$$\partial_\alpha \Theta^{\alpha\beta} = 0 \quad (12.116)$$

embodies Poynting's theorem and conservation of momentum for free fields. For example, with $\beta=0$ we have

$$0 = \partial_\alpha \Theta^{\alpha 0} = \frac{1}{c} \left(\frac{\partial u}{\partial t} + \nabla \cdot \mathbf{S} \right)$$

where $\mathbf{S} = c^2 \mathbf{g}$ is the Poynting vector. This is the sourcefree form of (6.108). Similarly, for $\beta=i$,

$$0 = \partial_\alpha \Theta^{\alpha i} = \frac{\partial g_i}{\partial t} - \sum_{j=1}^3 \frac{\partial}{\partial x_j} T_{ij}^{(M)}$$

a result equivalent to (6.121) in the absence of sources. The conservation of field angular momentum, defined through the tensor,

$$M^{\alpha\beta\gamma} = \Theta^{\alpha\beta} x^\gamma - \Theta^{\alpha\gamma} x^\beta \quad (12.117)$$

is assured by (12.116) and the symmetry of $\Theta^{\alpha\beta}$, as already discussed. There are evidently other conserved quantities in addition to energy, momentum, and angular momentum. The tensor $M^{\alpha\beta\gamma}$ has three time-space components in addition to the space-space components that give the angular momentum density. These three components are a necessary adjunct of the covariant generalization of angular momentum. Their conservation is a statement on the center of mass motion (see Problem 12.16).

(c) Conservation Laws for Electromagnetic Fields Interacting with Charged Particles

In the presence of external sources the Lagrangian for the Maxwell equations is (12.85). The symmetric stress tensor for the electromagnetic field retains its form (12.113), but the coupling to the source current makes its divergence nonvanishing. The calculation of the divergence is straightforward:

$$\begin{aligned} \partial_\alpha \Theta^{\alpha\beta} &= \frac{1}{4\pi} \left[\partial^\mu (F_{\mu\lambda} F^{\lambda\beta}) + \frac{1}{4} \partial^\beta (F_{\mu\lambda} F^{\mu\lambda}) \right] \\ &= \frac{1}{4\pi} \left[(\partial^\mu F_{\mu\lambda}) F^{\lambda\beta} + F_{\mu\lambda} \partial^\mu F^{\lambda\beta} + \frac{1}{2} F_{\mu\lambda} \partial^\beta F^{\mu\lambda} \right] \end{aligned}$$

The first term can be transformed by means of the inhomogeneous Maxwell equations (12.89). Transferring this term to the left-hand side, we have

$$\partial_\alpha \Theta^{\alpha\beta} + \frac{1}{c} F^{\beta\lambda} J_\lambda = \frac{1}{8\pi} F_{\mu\lambda} (\partial^\mu F^{\lambda\beta} + \underline{\partial^\mu F^{\lambda\beta} + \partial^\beta F^{\mu\lambda}})$$

The reason for the peculiar grouping of terms is that the underlined sum can be replaced, by virtue of the homogeneous Maxwell equation ($\partial^\mu F^{\lambda\beta} + \partial^\beta F^{\mu\lambda} +$

$\partial^\lambda F^{\beta\mu}=0$), by $-\partial^\lambda F^{\beta\mu}=+\partial^\lambda F^{\mu\beta}$. Thus we obtain

$$\partial_\alpha \Theta^{\alpha\beta} + \frac{1}{c} F^{\beta\lambda} J_\lambda = \frac{1}{8\pi} F_{\mu\lambda} (\partial^\mu F^{\lambda\beta} + \partial^\lambda F^{\mu\beta})$$

But the right-hand side is now the contraction (in μ and λ) of one symmetric and one antisymmetric factor. The result is therefore zero. The divergence of the stress tensor is thus

$$\partial_\alpha \Theta^{\alpha\beta} = -\frac{1}{c} F^{\beta\lambda} J_\lambda \quad (12.118)$$

The time and space components of this equation are

$$\frac{1}{c} \left(\frac{\partial u}{\partial t} + \nabla \cdot \mathbf{S} \right) = -\frac{1}{c} \mathbf{J} \cdot \mathbf{E} \quad (12.119)$$

and

$$\frac{\partial g_i}{\partial t} - \sum_{j=1}^3 \frac{\partial}{\partial x_j} T_{ij}^{(M)} = - \left[\rho E_i + \frac{1}{c} (\mathbf{J} \times \mathbf{B})_i \right] \quad (12.120)$$

These are just the conservation of energy and momentum equations of Chapter 6 for electromagnetic fields interacting with sources described by $J^\alpha = (c\rho, \mathbf{J})$. The 4-vector on the right-hand side of (12.118) is called the *Lorentz force density*,

$$f^\beta \equiv \frac{1}{c} F^{\beta\lambda} J_\lambda = \left(\frac{1}{c} \mathbf{J} \cdot \mathbf{E}, \rho \mathbf{E} + \frac{1}{c} \mathbf{J} \times \mathbf{B} \right) \quad (12.121)$$

If the sources are a number of charged particles, the volume integral of f^β leads through the Lorentz force equation (12.1) to the time rate of change of the sum of the energies or the momenta of all the particles:

$$\int f^\beta d^3x = \frac{dP_{\text{particles}}^\beta}{dt}$$

With the qualification expressed at the end of subsection (a) concerning covariance, the integral over 3-space at fixed time of the left-hand side of (12.118) is the time rate of change of the total energy or momentum of the field. We therefore have the conservation of 4-momentum for the combined system of particles and fields:

$$\int d^3x (\partial_\alpha \Theta^{\alpha\beta} + f^\beta) = \frac{d}{dt} (P_{\text{field}}^\beta + P_{\text{particles}}^\beta) = 0 \quad (12.122)$$

The above discussion has focused on the electromagnetic field, with charged particles only mentioned as the sources of the 4-current density. A more equitable treatment of a combined system of particles and fields involves a Lagrangian having three terms, a free-field Lagrangian, a free-particle Lagrangian, and an interaction Lagrangian that involves both field and particle degrees of freedom. Variation of the action integral with respect to the particle

coordinates leads to the Lorentz force equation, just as in Section 12.1, while variation of the field “coordinates” gives the Maxwell equations, as in Section 12.8. However, when self-energy and radiation reaction effects are included, the treatment is not quite so straightforward. References to these aspects are given at the end of the chapter.

Mention should also be made of the action-at-a-distance approach associated with the names of Schwarzschild, Tetrode, and Fokker. The emphasis is on the charged particles and an invariant action principle is postulated with the interaction term involving integrals over the world lines of all the particles. The idea of electromagnetic fields and the Maxwell equations is secondary. This approach is the basis of the Wheeler-Feynman absorber theory of radiation.*

12.11 Solution of the Wave Equation in Covariant Form, Invariant Green Functions

The electromagnetic fields $F^{\alpha\beta}$ arising from an external source $J^\alpha(x)$ satisfy the inhomogeneous Maxwell equations

$$\partial_\alpha F^{\alpha\beta} = \frac{4\pi}{c} J^\beta$$

With the definition of the fields in terms of the potentials this becomes

$$\square A^\beta - \partial^\beta(\partial_\alpha A^\alpha) = \frac{4\pi}{c} J^\beta$$

If the potentials satisfy the Lorentz condition, $\partial_\alpha A^\alpha = 0$, they are then solutions of the four-dimensional wave equation,

$$\square A^\beta = \frac{4\pi}{c} J^\beta(x) \quad (12.123)$$

The solution of (12.123) can be accomplished by finding a Green function $D(x, x')$ for the equation,

$$\square_x D(x, x') = \delta^{(4)}(x - x') \quad (12.124)$$

where $\delta^{(4)}(x - x') = \delta(x_0 - x'_0) \delta(\mathbf{x} - \mathbf{x}')$ is a four-dimensional delta function. In the absence of boundary surfaces, the Green function can depend only on the 4-vector difference $z^\alpha = x^\alpha - x'^\alpha$. Thus $D(x, x') = D(x - x') = D(z)$ and (12.124) becomes

$$\square_z D(z) = \delta^{(4)}(z)$$

We use Fourier integrals to transform from coordinate to wave number space.

* J. A. Wheeler and R. P. Feynman, *Rev. Mod. Phys.* **21**, 425 (1949).

The Fourier transform $\tilde{D}(k)$ of the Green function is defined by

$$D(z) = \frac{1}{(2\pi)^4} \int d^4k \tilde{D}(k) e^{-ik \cdot z} \quad (12.125)$$

where $k \cdot z = k_0 z_0 - \mathbf{k} \cdot \mathbf{z}$. With the representation of the delta function being

$$\delta^{(4)}(z) = \frac{1}{(2\pi)^4} \int d^4k e^{-ik \cdot z} \quad (12.126)$$

one finds that the k space Green function is

$$\tilde{D}(k) = -\frac{1}{k \cdot k} \quad (12.127)$$

The Green function $D(z)$ is therefore

$$D(z) = \frac{-1}{(2\pi)^4} \int d^4k \frac{e^{-ik \cdot z}}{k \cdot k} \quad (12.128)$$

Because the integrand in (12.128) is singular, the expression as it stands is ambiguous and is given definite meaning only by the handling of the singularities. We proceed by performing the integration over dk_0 first. Thus

$$D(z) = -\frac{1}{(2\pi)^4} \int d^3k e^{ik \cdot z} \int_{-\infty}^{\infty} dk_0 \frac{e^{-ik_0 z_0}}{k_0^2 - \kappa^2} \quad (12.129)$$

where we have introduced the notation, $\kappa = |\mathbf{k}|$. The k_0 integral is given meaning by considering k_0 as a complex variable and treating the integral as a contour integral in the k_0 plane. The integrand has two simple poles, at $k_0 = \pm \kappa$ as shown in Fig. 12.8. Green functions with differing behavior are obtained by choosing different contours of integration relative to the poles. Two possible contours are labeled r and a in Fig. 12.8. These open contours may be closed at infinity with a semicircle in the upper or lower half plane, depending upon the sign of z_0 in the exponential. For $z_0 > 0$, the exponential, $e^{-ik_0 z_0}$, increases without limit in the upper half plane. In order to use the residue theorem, we must therefore close the contour in the lower half plane. The opposite holds for $z_0 < 0$.

Fig. 12.8

Consider now the contour r . For $z_0 < 0$, the resulting integral vanishes because the contour is closed in the upper half plane and encircles no singularities. For $z_0 > 0$, the integral over k_0 is

$$\oint_r dk_0 \frac{e^{-ik_0 z_0}}{k_0^2 - \kappa^2} = -2\pi i \operatorname{Res} \left(\frac{e^{-ik_0 z_0}}{k_0^2 - \kappa^2} \right) \\ = -\frac{2\pi}{\kappa} \sin(\kappa z_0)$$

The Green function (12.129) is then

$$D_r(z) = \frac{\theta(z_0)}{(2\pi)^3} \int d^3k e^{i\mathbf{k} \cdot \mathbf{z}} \frac{\sin(\kappa z_0)}{\kappa}$$

The integration over the angles of \mathbf{k} leads to

$$D_r(z) = \frac{\theta(z_0)}{2\pi^2 R} \int_0^\infty d\kappa \sin(\kappa R) \sin(\kappa z_0) \quad (12.130)$$

where $R = |\mathbf{z}| = |\mathbf{x} - \mathbf{x}'|$ is the spatial distance between x^α and x'^α . Using some simple trigonometry and a change of variable (12.130) can be written

$$D_r(z) = \frac{\theta(z_0)}{8\pi^2 R} \int_{-\infty}^\infty d\kappa [e^{i(z_0 - R)\kappa} - e^{i(z_0 + R)\kappa}]$$

The remaining integrals are just Dirac delta functions. Because $z_0 > 0$ and $R > 0$ the second integral is always zero. The Green function for contour r is therefore

$$D_r(x - x') = \frac{\theta(x_0 - x'_0)}{4\pi R} \delta(x_0 - x'_0 - R) \quad (12.131)$$

Here we have reintroduced the original variables x and x' . This Green function is called the *retarded or causal Green function* because the source-point time x'_0 is always earlier than the observation-point time x_0 . Equation (12.131), or its Fourier transform with respect to x_0 , $(4\pi R)^{-1} e^{i\omega R/c}$, is the familiar Green function of outgoing waves of Chapter 6.

With the choice of the contour a in Fig. 12.8, an exactly parallel calculation yields the *advanced Green function*,

$$D_a(x - x') = \frac{\theta[-(x_0 - x'_0)]}{4\pi R} \delta(x_0 - x'_0 + R) \quad (12.132)$$

These Green functions can be put in covariant form by use of the following identity,

$$\delta[(x - x')^2] = \delta[(x_0 - x'_0)^2 - |\mathbf{x} - \mathbf{x}'|^2] \\ = \delta[(x_0 - x'_0 - R)(x_0 - x'_0 + R)] \\ = \frac{1}{2R} [\delta(x_0 - x'_0 - R) + \delta(x_0 - x'_0 + R)]$$

Then, since the theta functions select one or the other of the two terms, we have

$$\begin{aligned} D_r(x-x') &= \frac{1}{2\pi} \theta(x_0-x'_0) \delta[(x-x')^2] \\ D_a(x-x') &= \frac{1}{2\pi} \theta(x'_0-x_0) \delta[(x-x')^2] \end{aligned} \quad (12.133)$$

The theta functions, apparently noninvariant, when constrained by the delta functions, are actually invariant under proper Lorentz transformations. Thus (12.133) gives the Green functions an explicitly invariant expression. The theta and delta functions in (12.133) show that the retarded (advanced) Green function is different from zero only on the forward (backward) light cone of the source point.

The solution of the wave equation (12.123) can now be written down in terms of the Green functions:

$$A^\alpha(x) = A_{\text{in}}^\alpha(x) + \frac{4\pi}{c} \int d^4x' D_r(x-x') J^\alpha(x') \quad (12.134)$$

or

$$A^\alpha(x) = A_{\text{out}}^\alpha(x) + \frac{4\pi}{c} \int d^4x' D_a(x-x') J^\alpha(x') \quad (12.135)$$

where A_{in}^α and A_{out}^α are solutions of the homogeneous wave equation. In (12.134) the retarded Green function is used. In the limit $x_0 \rightarrow -\infty$, the integral over the sources vanishes, assuming the sources are localized in space and time, because of the retarded nature of the Green function. We see that the free-field potential $A_{\text{in}}^\alpha(x)$ has the interpretation of the “incident” or “incoming” potential, specified at $x_0 \rightarrow -\infty$. Similarly, in (12.135) with the advanced Green function, the homogeneous solution $A_{\text{out}}^\alpha(x)$ is the asymptotic “outgoing” potential, specified at $x_0 \rightarrow +\infty$. The *radiation fields* are defined as the difference between the “outgoing” and the “incoming” fields. Their 4-vector potential is

$$A_{\text{rad}}^\alpha(x) = A_{\text{out}}^\alpha - A_{\text{in}}^\alpha = \frac{4\pi}{c} \int d^4x' D(x-x') J^\alpha(x') \quad (12.136)$$

where

$$D(z) = D_r(z) - D_a(z) \quad (12.137)$$

is the difference between the retarded and advanced Green functions.

The fields of a charged particle moving in a prescribed path will be of interest in Chapter 14. If the particle is a point charge e whose position in the inertial frame K is $\mathbf{r}(t)$, its charge density and current density in that frame are

$$\left. \begin{aligned} \rho(\mathbf{x}, t) &= e \delta[\mathbf{x} - \mathbf{r}(t)] \\ \mathbf{J}(\mathbf{x}, t) &= e \mathbf{v}(t) \delta[\mathbf{x} - \mathbf{r}(t)] \end{aligned} \right\} \quad (12.138)$$

where $\mathbf{v}(t) = d\mathbf{r}(t)/dt$ is the charge's velocity in K . The charge and current

densities can be written as a 4-vector current in manifestly covariant form by introducing the charge's 4-vector coordinate $r^\alpha(\tau)$ as a function of the charge's proper time τ and integrating over the proper time with an appropriate additional delta function. Thus

$$J^\alpha(x) = ec \int d\tau U^\alpha(\tau) \delta^{(4)}[x - r(\tau)] \quad (12.139)$$

where U^α is the charge's 4-velocity. In the inertial frame K , $r^\alpha = [ct, \mathbf{r}(t)]$ and $U^\alpha = (\gamma c, \gamma \mathbf{v})$. The use of (12.139) in (12.134) to yield the potentials and fields of a moving charge is presented in Section 14.1.

REFERENCES AND SUGGESTED READING

The Lagrangian and Hamiltonian formalism for relativistic charged particles is treated in every advanced mechanics textbook, as well as in books on electrodynamics. Some useful references are

Barut, Chapter II,
Corben and Stehle, Chapter 16,
Goldstein, Chapter 6,
Landau and Lifshitz, *Classical Theory of Fields*, Chapters 2 and 3.

The motion of charged particles in external electromagnetic fields, especially inhomogeneous magnetic fields, is an increasingly important topic in geophysics, solar physics, and thermonuclear research. The classic reference for these problems is

Alfvén and Fälthammar,

but the basic results are also presented by
Chandrasekhar, Chapters 2 and 3,
Clemmow and Dougherty, Chapter 4,
Linhart, Chapter 1,
Spitzer, Chapter 1.

The book by

Rossi and Olbert

covers the motion of charged particles in the fields of the earth and sun. The topic of adiabatic invariants is treated thoroughly by

Northrop.

Another important application of relativistic charged-particle dynamics is to high-energy accelerators. An introduction to the physics problems of this field will be found in

Corben and Stehle, Chapter 17.

Some of the practical aspects as well as the basic physics of accelerators can be found in

Livingston and Blewett,
Persico, Ferrari, and Segre.

The Darwin Lagrangian (12.82) has been advocated as a useful tool in the description of low frequency oscillations in plasmas by

A. N. Kaufman and P. S. Rostler, *Physics of Fluids* **14**, 446 (1971).

It has also been used in an interesting paper by

S. Coleman and J. H. Van Vleck, *Phys. Rev.* **171**, 1370 (1968),

to resolve a paradox in the conservation of momentum and Newton's third law.

The subject of a Lagrangian description of fields is treated in

Barut, Chapter III,

Corben and Stehle, Chapter 15,

Goldstein, Chapter 11,

Schwartz, Chapter 6,

Wentzel, Chapter 1.

The general construction of the symmetric, gauge-invariant stress tensor $\Theta^{\alpha\beta}$ from $T^{\alpha\beta}$ is described in

Wentzel, Appendix,

Landau and Lifshitz, *Classical Theory of Fields*, Sections 32 and 94.

The particular questions of the interaction of charged particles and electromagnetic fields and the associated conservation laws are covered in

Barut, Chapters IV and V,

Landau and Lifshitz, *Classical Theory of Fields*, Chapter 4,

Schwartz, Chapter 7,

and in an especially thorough fashion by

Rohrlich,

who treats the self-energy and radiation reaction aspects in detail. For a careful discussion of the energy, momentum and mass of electromagnetic fields, consult Rohrlich's book, just cited, and also

F. Rohrlich, *Am. J. Phys.* **38**, 1310 (1970).

The invariant Green functions for the wave equation are derived in almost any book on quantum field theory. One such book, with a concise covariant treatment of classical electrodynamics at its beginning, is

Thirring, Sect. I.2 and Appendix II,

Two reviews on the subject of the photon mass, already cited in the Introduction, are

A. S. Goldhaber and M. M. Nieto, *Rev. Mod. Phys.* **43**, 277 (1971).

I. Yu. Kobzarev and L. B. Okun', *Uspekhi Fiz. Nauk.* **95**, 131 (1968) [English transl., *Sov. Phys. Uspekhi* **11**, 338 (1968)].

PROBLEMS

12.1 (a) Show that the Lorentz invariant Lagrangian,

$$L = -\frac{1}{2}mU_\alpha U^\alpha - \frac{q}{c}U_\alpha A^\alpha$$

gives the correct relativistic equations of motion for a particle of mass m and charge q interacting with an external field described by the 4-vector potential $A^\alpha(x)$.

(b) Define the canonical momenta and write out the effective Hamiltonian in both covariant and space-time form. The effective Hamiltonian is a Lorentz invariant. What is its value?

12.2 (a) Show from Hamilton's principle that Lagrangians which differ only by a total time derivative of some function of the coordinates and time are equivalent in the sense that they yield the same Euler-Lagrange equations of motion.

(b) Show explicitly that the gauge transformation $A^\alpha \rightarrow A^\alpha + \partial^\alpha \Lambda$ of the potentials in the charged-particle Lagrangian (12.9) merely generates another equivalent Lagrangian.

12.3 A particle interacts with an external Lorentz scalar potential.

(a) Use the Lorentz invariance of the action and the standard assumptions of translational and rotational invariance to show that the relativistic Lagrangian L must

be of the form (12.34), namely the free-particle Lagrangian times a Lorentz scalar function of x .

(b) Show that if the particle moves nonrelativistically in the frame K' the force in that frame is approximately $\mathbf{F}' = g\mathbf{E}'_{\text{eff}}$ where $\mathbf{E}'_{\text{eff}} = -\nabla'\phi$, and show that in the frame K there is thus a pseudomagnetic force, $g(\mathbf{u} \times \mathbf{B}_{\text{eff}})/c$, where $\mathbf{B}_{\text{eff}} = (\gamma_0/c)\mathbf{v} \times \mathbf{E}'_{\text{eff}}$.

(c) Show, however, by explicit substitution and transformation of $\partial^\alpha \phi(x)$ that the force equation (12.36) evaluated in K' leads via the transformation equations (12.32) for force to the same equation (12.36) in the frame K .

12.4 A particle with mass m and charge e moves in a uniform, static, electric field \mathbf{E}_0 .

(a) Solve for the velocity and position of the particle as explicit functions of time, assuming that the initial velocity \mathbf{v}_0 was perpendicular to the electric field.

(b) Eliminate the time to obtain the trajectory of the particle in space. Discuss the shape of the path for short and long times (define "short" and "long" times).

12.5 It is desired to make an $\mathbf{E} \times \mathbf{B}$ velocity selector with uniform, static, crossed, electric and magnetic fields over a length L . If the entrance and exit slit widths are Δx , discuss the interval Δu of velocities, around the mean value $u = cE/B$, that is transmitted by the device as a function of the mass, the momentum or energy of the incident particles, the field strengths, the length of the selector, and any other relevant variables. Neglect fringing effects at the ends. Base your discussion on the practical facts that $L \sim$ few meters, $E_{\text{max}} \sim 3 \times 10^4$ volts/cm, $\Delta x \sim 10^{-1}$ to 10^{-2} cm, $u \sim 0.5$ to $0.995c$. (It is instructive to consider the equation of motion in a frame moving at the mean speed u along the beam direction, as well as in the laboratory.) References: C. A. Coombes et al., *Phys. Rev.* **112**, 1303 (1958); P. Eberhard, M. L. Good, and H. K. Ticho, *Rev. Sci. Inst.* **31**, 1054 (1960).

12.6 A particle of mass m and charge e moves in the laboratory in crossed, static, uniform, electric and magnetic fields. \mathbf{E} is parallel to the x axis; \mathbf{B} is parallel to the y axis.

(a) For $|\mathbf{E}| < |\mathbf{B}|$ make the necessary Lorentz transformation described in Section 12.4 to obtain explicitly parametric equations for the particle's trajectory.

(b) Repeat the calculation of (a) for $|\mathbf{E}| > |\mathbf{B}|$.

12.7 Static, uniform electric and magnetic fields, \mathbf{E} and \mathbf{B} , make an angle of θ with respect to each other.

(a) By a suitable choice of axes, solve the force equation for the motion of a particle of charge e and mass m in rectangular coordinates.

(b) For \mathbf{E} and \mathbf{B} parallel, show that with appropriate constants of integration, etc., the parametric solution can be written

$$x = AR \sin \phi, \quad y = AR \cos \phi, \quad z = \frac{R}{\rho} \sqrt{1 + A^2} \cosh(\rho\phi)$$

$$ct = \frac{R}{\rho} \sqrt{1 + A^2} \sinh(\rho\phi)$$

where $R = (mc^2/eB)$, $\rho = (E/B)$, A is an arbitrary constant, and ϕ is the parameter [actually c/R times the proper time].

12.8 The magnetic field of the earth can be represented approximately by a magnetic dipole of magnetic moment $M = 8.1 \times 10^{25}$ gauss-cm³. Consider the motion of energetic electrons in the neighborhood of the earth under the action of this dipole field (Van Allen electron belts). [Note that \mathbf{M} points south.]

(a) Show that the equation for a line of magnetic force is $r = r_0 \sin^2 \theta$, where θ is the usual polar angle (colatitude) measured from the axis of the dipole, and find an expression for the magnitude of B along any line of force as a function of θ .

(b) A positively charged particle circles around a line of force in the equatorial plane with a gyration radius a and a mean radius R ($a \ll R$). Show that the particle's azimuthal position (east longitude) changes approximately linearly in time according to

$$\phi(t) = \phi_0 - \frac{3}{2} \left(\frac{a}{R} \right)^2 \omega_B (t - t_0)$$

where ω_B is the frequency of gyration at radius R .

(c) If, in addition to its circular motion of (b), the particle has a small component of velocity parallel to the lines of force, show that it undergoes small oscillations in θ around $\theta = \pi/2$ with a frequency $\Omega = (3/\sqrt{2})(a/R)\omega_B$. Find the change in longitude per cycle of oscillation in latitude.

(d) For an electron of 10 MeV kinetic energy at a mean radius $R = 3 \times 10^9$ cm, find ω_B and a , and so determine how long it takes to drift once around the earth and how long it takes to execute one cycle of oscillation in latitude. Calculate these same quantities for an electron of 10 keV at the same radius.

12.9 A charged particle finds itself instantaneously in the equatorial plane of the earth's magnetic field (assumed to be a dipole field) at a distance R from the center of the earth. Its velocity vector at that instant makes an angle α with the equatorial plane ($v_{\parallel}/v_{\perp} = \tan \alpha$). Assuming that the particle spirals along the lines of force with a gyration radius $a \ll R$, and that the flux linked by the orbit is a constant of the motion, find an equation for the maximum magnetic latitude λ reached by the particle as a function of the angle α . Plot a graph (*not a sketch*) of λ versus α . Mark parametrically along the curve the values of α for which a particle at radius R in the equatorial plane will hit the earth (radius R_0) for $R/R_0 = 1.2, 1.5, 2.0, 2.5, 3, 4, 5$.

12.10 Consider the precession of the spin of a muon, initially longitudinally polarized, as the muon moves in a circular orbit in a plane perpendicular to a uniform magnetic field \mathbf{B} .

(a) Show that the difference Ω of the spin precession frequency and the orbital gyration frequency is

$$\Omega = \frac{eBa}{m_{\mu}c}$$

independent of the muon's energy, where $a = (g-2)/2$ is the magnetic moment anomaly. (Find equations of motion for the components of spin along the mutually perpendicular directions defined by the particle's velocity, the radius vector from the center of the circle to the particle, and the magnetic field.)

(b) For the CERN Muon Storage Ring [referred to in Section 11.1(c)], the orbit radius is $R = 2.5$ meters and $B = 17 \times 10^3$ gauss. What is the momentum of the muon? What is the time dilatation factor γ ? How many periods of precession $T = 2\pi/\Omega$ occur per observed laboratory mean lifetime of the muons? [$m_{\mu} = 105.66$ MeV, $\tau_0 = 2.2 \times 10^{-6}$ sec, $a \approx \alpha/2\pi$].

(c) Express the difference frequency Ω in units of the orbital rotation frequency and compute how many precessional periods (at the difference frequency) occur per rotation for a 300 MeV muon, a 300 MeV electron, a 5 GeV electron (this last typical of e^+e^- storage rings at Stanford and Hamburg).

12.11 In Section 11.11 the BMT equation of motion for the spin of a particle of charge e and a magnetic moment with an arbitrary g factor was obtained.

(a) Verify that (11.171) is the correct equation for the time derivative of the longitudinal component of the rest-frame spin vector \mathbf{s} .

(b) Let $\hat{\mathbf{n}}$ be a unit 3-vector perpendicular to $\hat{\boldsymbol{\beta}}$ and coplanar with $\hat{\boldsymbol{\beta}}$ and \mathbf{s} ($\hat{\mathbf{n}}$ is generally time-dependent). Let θ be the angle between $\hat{\boldsymbol{\beta}}$ and \mathbf{s} . Show that the time rate of change of θ can be written as

$$\frac{d\theta}{dt} = \frac{e}{mc} \left[\left(\frac{g}{2} - 1 \right) \hat{\mathbf{n}} \cdot (\hat{\boldsymbol{\beta}} \times \mathbf{B}) + \left(\frac{g\beta}{2} - \frac{1}{\beta} \right) \hat{\mathbf{n}} \cdot \mathbf{E} \right]$$

where \mathbf{E} and \mathbf{B} are the fields in the laboratory and $c\boldsymbol{\beta} = c\beta\hat{\boldsymbol{\beta}}$ is the particle's instantaneous velocity in the laboratory.

(c) For a particle moving undeflected through an $E \times B$ velocity selector and with $(\hat{\mathbf{n}} \times \hat{\boldsymbol{\beta}}) \cdot \mathbf{B} = B$, find $d\theta/dt$ in terms of the gyration frequency $eB/\gamma mc$.

(d) By defining the two 4-vectors, $L^\alpha = (\gamma\beta, \gamma\hat{\boldsymbol{\beta}})$ and $N^\alpha = (0, \hat{\mathbf{n}})$, show that $d\theta/d\tau$ can be written in the quasi-covariant form,

$$\frac{d\theta}{d\tau} = \frac{e}{mc} \left[\frac{g}{2} L_\alpha - \frac{1}{v} U_\alpha \right] F^{\alpha\beta} N_\beta$$

where U^α is the particle's 4-velocity.

12.12 (a) Specialize the Darwin Lagrangian (12.82) to the interaction of two charged particles (m_1, q_1) and (m_2, q_2) . Introduce reduced particle coordinates, $\mathbf{r} = \mathbf{x}_1 - \mathbf{x}_2$, $\mathbf{v} = \mathbf{v}_1 - \mathbf{v}_2$ and also center of mass coordinates. Write out the Lagrangian in the reference frame in which the velocity of the center of mass vanishes and evaluate the canonical momentum components, $p_x = \partial L / \partial v_x$, etc.

(b) Calculate the Hamiltonian to first order in $1/c^2$ and show that it is

$$H = \frac{p^2}{2} \left(\frac{1}{m_1} + \frac{1}{m_2} \right) + \frac{q_1 q_2}{r} - \frac{p^4}{8c^2} \left(\frac{1}{m_1^3} + \frac{1}{m_2^3} \right) + \frac{q_1 q_2}{2m_1 m_2 c^2} \left(\frac{p^2 + (\mathbf{p} \cdot \hat{\mathbf{r}})^2}{r} \right)$$

Compare with the various terms in (42.1) on p. 193 of Bethe and Salpeter (*op. cit.*). Discuss the agreements and disagreements.

12.13 An alternative Lagrangian density for the electromagnetic field is

$$\mathcal{L} = -\frac{1}{8\pi} \partial_\alpha A_\beta \partial^\alpha A^\beta - \frac{1}{c} J_\alpha A^\alpha$$

(a) Derive the Euler-Lagrange equations of motion. Are they the Maxwell equations? Under what assumptions?

(b) Show explicitly, and with what assumptions, that this Lagrangian density differs from (12.85) by a 4-divergence. Does this added 4-divergence affect the action or the equations of motion?

12.14 Consider the Proca equations for a localized steady state distribution of current that has only a static magnetic moment. This model can be used to study the observable effects of a finite photon mass on the earth's magnetic field. Note that if the magnetization is $\mathcal{M}(\mathbf{x})$ the current density can be written as $\mathbf{J} = c(\nabla \times \mathcal{M})$.

(a) Show that if $\mathcal{M} = \mathbf{m}f(\mathbf{x})$, where \mathbf{m} is a fixed vector and $f(\mathbf{x})$ is a localized scalar function, the vector potential is

$$\mathbf{A}(\mathbf{x}) = -\mathbf{m} \times \nabla \int f(\mathbf{x}') \frac{e^{-\mu|\mathbf{x}-\mathbf{x}'|}}{|\mathbf{x}-\mathbf{x}'|} d^3x'$$

(b) If the magnetic dipole is a point dipole at the origin show that the magnetic field is

$$\mathbf{B}(\mathbf{x}) = [3\hat{\mathbf{r}}(\hat{\mathbf{r}} \cdot \mathbf{m}) - \mathbf{m}] \left(1 + \mu r + \frac{\mu^2 r^2}{3} \right) \frac{e^{-\mu r}}{r^3} - \frac{2}{3} \mu^2 \mathbf{m} \frac{e^{-\mu r}}{r}$$

(c) The result of (b) shows that at fixed $r = R$ (on the surface of the earth), the earth's magnetic field will appear as a dipole angular distribution, plus an added constant magnetic field (an apparently external field) antiparallel to \mathbf{m} . Satellite and surface observations lead to the conclusion that this "external" field is less than 4×10^{-3} times the dipole field at the magnetic equator. Estimate a lower limit on μ^{-1} in earth radii and an upper limit on the photon mass in grams from this datum.

This method of estimating μ is due to E. Schrödinger, *Proc. Roy. Irish Acad.* **A49**, 135 (1943). See A. S. Goldhaber and M. M. Nieto, *Phys. Rev. Letters* **21**, 567 (1968).

12.15 Prove, by means of the divergence theorem in four dimensions or otherwise, that for sourcefree electromagnetic fields confined to a finite region of space the 3-space integrals of Θ^{00} and Θ^{0i} transform as the components of a 4-vector, as implied by (12.106).

12.16 Sourcefree electromagnetic fields exist in a localized region of space. Consider the various conservation laws that are contained in the integral of $\partial_\alpha M^{\alpha\beta\gamma} = 0$ over all space, where $M^{\alpha\beta\gamma}$ is defined by (12.117).

(a) Show that when β and γ are both space indices conservation of the total field angular momentum follows.

(b) Show that when $\beta = 0$ the conservation law is

$$\frac{d\mathbf{X}}{dt} = \frac{c^2 \mathbf{P}_{em}}{E_{em}}$$

where \mathbf{X} is the coordinate of the center of mass of the electromagnetic fields, defined by

$$\mathbf{X} \int u d^3x = \int \mathbf{x} u d^3x$$

where u is the electromagnetic energy density and E_{em} and \mathbf{P}_{em} are the total energy and momentum of the fields.

13

Collisions between Charged Particles, Energy Loss, and Scattering

In this chapter collisions between swiftly moving, charged particles are considered, with special emphasis on the exchange of energy between collision partners and on the accompanying deflections from the incident direction. A fast charged particle incident on matter makes collisions with the atomic electrons and nuclei. If the particle is heavier than an electron (μ or π meson, K meson, proton, etc.), the collisions with electrons and with nuclei have different consequences. The light electrons can take up appreciable amounts of energy from the incident particle without causing significant deflections, whereas the massive nuclei absorb very little energy but because of their greater charge cause scattering of the incident particle. Thus loss of energy by the incident particle occurs almost entirely in collisions with electrons. The deflection of the particle from its incident direction results, on the other hand, from essentially elastic collisions with the atomic nuclei. The scattering is confined to rather small angles, so that a heavy particle keeps a more or less straight-line path while losing energy until it nears the end of its range. For incident electrons both energy loss and scattering occur in collisions with the atomic electrons. Consequently the path is much less straight. After a short distance, electrons tend to diffuse into the material, rather than go in a rectilinear path.

The subject of energy loss and scattering is an important one and is discussed in several books* where numerical tables and graphs are presented. Consequently our discussion will emphasize the physical ideas involved, rather than the exact numerical formulas. Indeed, a full quantum-mechanical treatment is needed to obtain exact results, even though all the essential features are classical or semiclassical in origin. The order of magnitude of the quantum effects are all easily derivable from the uncertainty principle, as will be seen in what follows.

We will begin by considering the simple problem of energy transfer to a free electron by a fast heavy particle. Then the effects of a binding force on the

* See references at the end of the chapter.

electron are explored, and the classical Bohr formula for energy loss is obtained. Quantum modifications and the effect of the polarization of the medium are described, followed by a discussion of the closely related phenomenon of Cherenkov radiation in transparent materials. The energy loss in an electronic plasma is considered briefly. Finally the elastic scattering of incident particles by nuclei and multiple scattering are presented.

13.1 Energy Transfer in a Coulomb Collision

A swift particle of charge ze and mass M collides with an electron in an atom. If the particle moves rapidly compared to the characteristic velocity of the electron in its orbit, during the collision the electron can be treated as free and initially at rest. As further approximations we will assume that the momentum transfer Δp is sufficiently small that the incident particle is essentially undeflected from its straight-line path, and that the recoiling electron does not move appreciably during the collision. Then to find the energy transfer during the collision we need only calculate the momentum impulse caused by the electric field of the incident particle at the position of the electron. The particle's magnetic field is of negligible importance if the electron is essentially at rest.

Figure 13.1 shows the geometry of the collision. The incident particle has a velocity v and an energy $E = \gamma Mc^2$. It passes the electron of charge $-e$ and mass $m \ll M$ at an impact parameter b . At the position of the electron the fields of the incident particle are given by (11.152) with $q = ze$. Only the transverse electric field E_2 has a nonvanishing time integral. Consequently the momentum impulse Δp is in the transverse direction and has the magnitude

$$\Delta p = \int_{-\infty}^{\infty} eE_2(t) dt = \frac{2ze^2}{bv} \quad (13.1)$$

It should be noted that Δp is independent of γ , as discussed at the end of Section 11.10. The energy transferred to the electron is

$$\Delta E(b) = \frac{(\Delta p)^2}{2m} = \frac{2z^2e^4}{mv^2} \left(\frac{1}{b^2} \right) \quad (13.2)$$

The angular deflection of the incident particle is given by $\theta \approx \Delta p/p$, provided

Fig. 13.1

$\Delta p \ll p$. Thus, for small deflections,

$$\theta \approx \frac{2ze^2}{p v b} \quad (13.3)$$

This result can be compared with the well-known exact expression for the Rutherford scattering of a nonrelativistic particle of charge ze by a Coulomb force field of charge $z'e$:

$$2 \tan \frac{\theta}{2} = \frac{2zz'e^2}{p v b} \quad (13.4)$$

We see that for small angles the two expressions agree.*

The energy transfer $\Delta E(b)$ given by (13.2) has several interesting features. It depends only on the charge and velocity of the incident particle, not on its mass. It varies inversely as the square of the impact parameter so that close collisions involve very large energy transfers. There is, of course, an upper limit on the energy transfer, corresponding to a head-on collision. Our method of calculation is really valid only for large values of b . We can obtain a lower limit b_{\min} on the impact parameter for which our approximate calculation is valid by equating (13.2) to the maximum allowable energy transfer [see Problem 11.23(b)]:

$$\Delta E(b_{\min}) = \Delta E_{\max} \approx 2m\gamma^2 v^2 \quad (13.5)$$

This yields the lower bound,

$$b_{\min} = \frac{ze^2}{\gamma m v^2} \quad (13.6)$$

below which our approximate result (13.2) must be replaced by a more exact expression which tends to (13.5) as $b \rightarrow 0$. It can be shown (Problem 13.1) that a proper treatment gives the more accurate result,

$$\Delta E(b) \approx \frac{2z^2 e^4}{m v^2} \left(\frac{1}{b_{\min}^2 + b^2} \right) \quad (13.7)$$

Equation (13.7) exhibits the proper limiting behavior as $b \rightarrow 0$ and reduces to (13.2) for $b \gg b_{\min}$.

The lower limit on b can be obtained by another argument. Equation (13.2) was derived under the assumption that the electron did not move appreciably during the collision. As long as the distance d it actually moves is small compared to b , we may expect that (13.2) will be correct. An estimate of d can be obtained by saying that $\Delta p/2m$ is an average velocity of the electron during

* Actually there is a question of reference frames in comparing (13.3) and (13.4). Since (13.4) holds for a fixed center of force (or the cm system), we should compare it with the result for the deflection of the light electron in the frame where the heavy incident particle is at rest. Then (13.3) holds with $p \approx \gamma m v$ as the electron momentum in that frame. The reader may verify that (13.3) and (13.4) are also consistent in the frame in which the electron is at rest by transforming angles from the cm system to the laboratory.

the collision, and that the time of collision is given by (11.153), $\Delta t \approx b/\gamma v$. Hence the distance traveled during the collision is of the order of

$$d \sim \frac{\Delta p}{2m} \times \Delta t = \frac{ze^2}{\gamma m v^2} = b_{\min} \quad (13.8)$$

As long as $b \gg d$, (13.2) should hold. This is exactly the condition implied by (13.7).

At the other extreme of very distant collisions the approximate result (13.2) for $\Delta E(b)$ is in error because of the binding of the atomic electrons. We assumed that the electrons were free, whereas they are actually bound in atoms. As long as the collision time (11.153) is short compared to the orbital period of motion, it may be expected that the collision will be sudden enough that the electron may be treated as free. If, on the other hand, the collision time is very long compared to the orbital period, the electron will make many cycles of motion as the incident particle passes slowly by and will be influenced adiabatically by the fields with no net transfer of energy. The dividing point comes at impact parameter b_{\max} , where the collision time (11.153) and the orbital period are comparable. If ω is a characteristic atomic frequency of motion, this condition is

$$\left. \begin{array}{l} \Delta t(b_{\max}) \sim \frac{1}{\omega} \\ b_{\max} = \frac{\gamma v}{\omega} \end{array} \right\} \quad \text{or} \quad (13.9)$$

For impact parameters greater than b_{\max} it can be expected that the energy transfer falls below (13.2), going rapidly to zero for $b \gg b_{\max}$.

The general behavior of $\Delta E(b)$ as a function of b is shown in Fig. 13.2. The dotted curve represents the approximate form (13.2), while the solid curve is a representation of the correct result. In the interval $b_{\min} < b < b_{\max}$ the energy transfer is given approximately by (13.2). But for impact parameters outside that interval, the energy transfer is considerably less.

A fast particle passing through matter "sees" electrons at various distances from its path. If there are N atoms per unit volume with Z electrons per atom, the number of electrons located at impact parameters between b and $(b+db)$ in a thickness dx of matter is

$$dn = NZ \, 2\pi b \, db \, dx \quad (13.10)$$

To find the energy lost per unit distance by the incident particle we multiply (13.10) by the energy transfer $\Delta E(b)$ and integrate over all impact parameters. Thus the energy loss is

$$\frac{dE}{dx} = 2\pi NZ \int \Delta E(b) b \, db \quad (13.11)$$

In view of the behavior of $\Delta E(b)$ shown in Fig. 13.2 we may use approximation

Fig. 13.2 Energy transfer as a function of impact parameter.

(13.2) and integrate between b_{\min} and b_{\max} . Then we find the result

$$\frac{dE}{dx} \approx 4\pi NZ \frac{z^2 e^4}{mv^2} \int_{b_{\min}}^{b_{\max}} \frac{1}{b^2} b db \quad (13.12)$$

or

$$\frac{dE}{dx} \approx 4\pi NZ \frac{z^2 e^4}{mv^2} \ln B \quad (13.13)$$

where

$$B = \frac{b_{\max}}{b_{\min}} \approx \frac{\gamma^2 mv^3}{ze^2 \omega} \quad (13.14)$$

This approximate expression for the energy loss exhibits all the essential features of the classical result due to Bohr (1915). The method of handling the lower limit of integration (13.12) is completely equivalent to using (13.7) for $\Delta E(b)$. The cutoff at $b = b_{\max}$ is only approximate. Consequently B is uncertain by a factor of the order of unity. Because B appears in the logarithm, this factor is of negligible

importance numerically. In any event, a proper treatment of binding effects is given in the next section. Discussion of (13.13) as a function of energy and its comparison with experiment will be deferred until Section 13.3.

13.2 Energy Transfer to a Harmonically Bound Charge

In order to justify the plausible value b_{\max} (13.9) of the impact parameter which divides the Coulomb collisions for $b < b_{\max}$ with the free-energy transfer (13.2) and essentially adiabatic collisions for $b > b_{\max}$ with negligible energy transfer, we consider the problem of the energy lost by a massive charged particle with charge ze and velocity v passing a harmonically bound charge of mass m and charge $-e$. This will serve as a simplified model for energy loss of particles passing through matter. As before, we will assume that the massive particle is deflected only slightly in the encounter so that its path can be approximated by a straight line. It passes by the bound particle at an impact parameter b , measured from the origin O of the binding force, as shown in Fig. 13.3. Since we are primarily interested in large impact parameters where binding effects are important, we may assume that the energy transfer is not large, that the motion of the bound particle is nonrelativistic throughout the collision, and that its initial and final amplitudes of oscillation about the origin O are small compared to b . Then only the electric field of the incident particle need be included in the force equation. Furthermore, its variation over the position of the bound particle may be neglected, and its effective value can be taken as that at the origin O . This is sometimes called the *dipole approximation*, by analogy with the corresponding problem of absorption of radiation.

With these approximations the force equation for the harmonically bound charge can be written as

$$\ddot{\mathbf{x}} + \Gamma \dot{\mathbf{x}} + \omega_0^2 \mathbf{x} = -\frac{e}{m} \mathbf{E}(t) \quad (13.15)$$

where $\mathbf{E}(t)$ is the electric field at O due to the charge ze , its components being given by (11.152), ω_0 is the characteristic frequency of the binding, and Γ is a small damping constant. The damping factor is not essential, but it is present to at least some degree in actual physical systems and serves to remove certain ambiguities which would arise in its absence. To solve (13.15) we Fourier-analyze both $\mathbf{E}(t)$ and $\mathbf{x}(t)$:

$$\mathbf{x}(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \mathbf{x}(\omega) e^{-i\omega t} d\omega \quad (13.16)$$

$$\mathbf{E}(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \mathbf{E}(\omega) e^{-i\omega t} d\omega \quad (13.17)$$

Since both $\mathbf{x}(t)$ and $\mathbf{E}(t)$ are real, the positive and negative frequency parts of their transforms are related by

$$\begin{aligned} \mathbf{x}(-\omega) &= \mathbf{x}^*(\omega) \\ \mathbf{E}(-\omega) &= \mathbf{E}^*(\omega) \end{aligned} \quad (13.18)$$

Fig. 13.3

When the Fourier integral forms are substituted into the force equation, we find

$$\mathbf{x}(\omega) = -\frac{e}{m} \frac{\mathbf{E}(\omega)}{\omega_0^2 - i\omega\Gamma - \omega^2} \quad (13.19)$$

With the known form of $\mathbf{E}(t)$ the Fourier amplitude $\mathbf{E}(\omega)$ can be determined. Then $\mathbf{x}(t)$ can be found from (13.16), using (13.19). The problem is solved, provided one can do the integrals.

The quantity of immediate interest is not the detailed motion of the bound particle, but the energy transfer in the collision. This can be found by considering the work done by the incident particle on the bound one. The rate of doing work is given by

$$\frac{dE}{dt} = \int \mathbf{E} \cdot \mathbf{J} d^3x' \quad (13.20)$$

Thus the total work done by the particle passing by is

$$\Delta E = \int_{-\infty}^{\infty} dt \int d^3x' \mathbf{E} \cdot \mathbf{J} \quad (13.21)$$

The current density is $\mathbf{J} = -e\mathbf{v} \delta[\mathbf{x}' - \mathbf{x}(t)]$ for the bound charge. Consequently

$$\Delta E = -e \int_{-\infty}^{\infty} \mathbf{v} \cdot \mathbf{E} dt \quad (13.22)$$

where $\mathbf{v} = \dot{\mathbf{x}}$, and in the dipole approximation \mathbf{E} is the field of the incident particle at the origin O . Using the Fourier representations (13.16) and (13.17), as well as that for a delta function (2.46), and the reality conditions (13.18), the energy transfer can be written

$$\Delta E = 2e \operatorname{Re} \int_0^{\infty} i\omega \mathbf{x}(\omega) \cdot \mathbf{E}^*(\omega) d\omega \quad (13.23)$$

If now the result (13.19) for $\mathbf{x}(\omega)$ is inserted, this becomes

$$\Delta E = \frac{e^2}{m} \int_0^{\infty} |\mathbf{E}(\omega)|^2 \frac{2\omega^2\Gamma}{(\omega_0^2 - \omega^2)^2 + \omega^2\Gamma^2} d\omega \quad (13.24)$$

For small Γ the integrand peaks sharply around $\omega = \omega_0$ in an approximately Lorentzian line shape. Consequently the factor involving the electric field can be approximated by its value at $\omega = \omega_0$. Then (13.24) becomes

$$\Delta E = \frac{2e^2}{m} |\mathbf{E}(\omega_0)|^2 \int_0^\infty \frac{x^2 dx}{\left(\frac{\omega_0^2}{\Gamma^2} - x^2\right)^2 + x^2} \quad (13.25)$$

The integral has the value $\pi/2$, independent of ω_0/Γ . Thus the energy transfer is

$$\Delta E = \frac{\pi e^2}{m} |\mathbf{E}(\omega_0)|^2 \quad (13.26)$$

Equation (13.26) is a very general result for energy transfer to a nonrelativistic oscillator by an external electromagnetic field. In the present application the field is produced by a passing charged particle. But a pulse of radiation or any combination of external fields will serve as well.

For a particle with charge ze passing by the origin O at an impact parameter b with a velocity v , the electromagnetic fields at the origin are given by (11.152) with $q = ze$. To illustrate the determination of the Fourier transform (13.17) we consider $E_2(t)$. Its transform $E_2(\omega)$ is defined to be

$$E_2(\omega) = \frac{zebv}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{e^{i\omega t} dt}{(b^2 + \gamma^2 v^2 t^2)^{3/2}} \quad (13.27)$$

By changing integration variable to $x = \gamma vt/b$, (13.27) can be written as

$$E_2(\omega) = \frac{ze}{\sqrt{2\pi} bv} \int_{-\infty}^{\infty} \frac{e^{i\omega bx/\gamma v}}{(1+x^2)^{3/2}} dx \quad (13.28)$$

From a table of Fourier transforms* we find that the integral is proportional to a modified Bessel function of order unity [see (3.101)]. Thus

$$E_2(\omega) = \frac{ze}{bv} \left(\frac{2}{\pi}\right)^{1/2} \left[\frac{\omega b}{\gamma v} K_1\left(\frac{\omega b}{\gamma v}\right) \right] \quad (13.29)$$

Similarly $E_1(t)$ given by (11.152) has the Fourier transform:

$$E_1(\omega) = -i \frac{ze}{\gamma vb} \left(\frac{2}{\pi}\right)^{1/2} \left[\frac{\omega b}{\gamma v} K_0\left(\frac{\omega b}{\gamma v}\right) \right] \quad (13.30)$$

The energy transfer (13.26) to the harmonically bound charge can now be evaluated explicitly. Using (13.29) and (13.30), we find

$$\Delta E(b) = \frac{2z^2 e^4}{mv^2} \left(\frac{1}{b^2}\right) \left[\xi^2 K_1^2(\xi) + \frac{1}{\gamma^2} \xi^2 K_0^2(\xi) \right] \quad (13.31)$$

* See, for example, Magnus and Oberhettinger, Chapter VIII, or Bateman Manuscript Project, *Tables of Integral Transforms*, Vol. I, Chapters I-III.

where

$$\xi = \frac{\omega_0 b}{\gamma v} \quad (13.32)$$

The factor multiplying the square bracket is just the approximate result (13.2). For small and large ξ , the limiting forms (3.103) and (3.104) show that the square bracket in (13.31) has the limiting values:

$$[] = \begin{cases} 1, & \text{for } \xi \ll 1 \\ \left(1 + \frac{1}{\gamma^2}\right) \frac{\pi}{2} \xi e^{-2\xi} & \text{for } \xi \gg 1 \end{cases} \quad (13.33)$$

Since $\xi = b/b_{\max}$, we see that for $b \ll b_{\max}$ the energy transfer is essentially the approximate result (13.2), while for $b \geq b_{\max}$ it falls off exponentially to zero. This justifies the qualitative arguments of the previous section on the upper limit b_{\max} .

13.3 Classical and Quantum-Mechanical Energy-Loss Formulas

The energy transfer (13.31) to a harmonically bound charge can be used to calculate a classical energy loss per unit length for a fast, heavy particle passing through matter. We suppose that there are N atoms per unit volume with Z electrons per atom. The Z electrons can be divided into groups specified by the index j , with f_j electrons having the same harmonic binding frequency ω_j . The number f_j is called the *oscillator strength* of the j th oscillator. The oscillator strengths satisfy the obvious sum rule, $\sum_j f_j = Z$. By a trivial extension of the arguments leading to (13.11) and (13.12) we find the energy loss to be

$$\frac{dE}{dx} = 2\pi N \sum_j f_j \int_{b_{\min}}^{\infty} \Delta E_j(b) b db \quad (13.34)$$

where $\Delta E_j(b)$ is given by (13.31) with $\xi = \omega_j b / \gamma v$, and a lower limit of b_{\min} is specified, consistent with (13.7). No upper limit is necessary, since (13.31) falls rapidly to zero for large b . The integral over the modified Bessel functions can be done in closed form, leading to the result,

$$\frac{dE}{dx} = \frac{4\pi N Z^2 e^4}{m v^2} \sum_j f_j \left[\xi_{\min} K_1(\xi_{\min}) K_0(\xi_{\min}) - \frac{v^2}{2c^2} \xi_{\min}^2 (K_1^2(\xi_{\min}) - K_0^2(\xi_{\min})) \right] \quad (13.35)$$

where $\xi_{\min} = \omega_j b_{\min} / \gamma v$. In general, $\xi_{\min} \ll 1$. This means that the limiting forms (3.103) may be used to simplify (13.35). This final expression for classical energy loss is

$$\frac{dE_c}{dx} = 4\pi N Z \frac{z^2 e^4}{m v^2} \left[\ln B_c - \frac{v^2}{2c^2} \right] \quad (13.36)$$

where the argument of the logarithm is

$$B_c = \frac{1.123\gamma v}{\langle\omega\rangle b_{\min}} = \frac{1.123\gamma^2 m v^3}{ze^2\langle\omega\rangle} \quad (13.37)$$

The average frequency $\langle\omega\rangle$ appearing in B_c is a geometric mean defined by

$$Z \ln \langle\omega\rangle = \sum_i f_i \ln \omega_i \quad (13.38)$$

The result (13.36)–(13.38) is that obtained by Bohr in his classic paper on energy loss (1915). Our approximate expression (13.13) is in agreement with (13.36) in all its essentials, since the added $-v^2/2c^2$ is a small correction even at high velocities.

Bohr's formula (13.36) gives a reasonable description of the energy loss of relatively slow alpha particles and heavier nuclei. But for electrons, mesons, protons, and even fast alphas, it overestimates the energy loss considerably. The reason is that for the lighter particles quantum-mechanical modifications cause a breakdown of the classical result. The important quantum effects are (1) discreteness of the possible energy transfers, and (2) limitations due to the wave nature of the particles and the uncertainty principle.

The problem of the discrete nature of the energy transfer can be illustrated by calculating the classical energy transfer (13.2) at $b \approx b_{\max}$. This is roughly the smallest energy transfer that is of importance in the energy-loss process. Assuming only one binding frequency ω_0 for simplicity, we find

$$\Delta E(b_{\max}) \approx \frac{1}{\gamma^2} z^2 \left(\frac{v_0}{v}\right)^4 \hbar \omega_0 \left(\frac{\hbar \omega_0}{I_H}\right) \quad (13.39)$$

where $v_0 = c/137$ is the orbital velocity of an electron in the ground state of hydrogen and $I_H = me^4/2\hbar^2 = 13.6$ eV is the ionization potential in hydrogen. Since $\hbar\omega_0$ is of the order of the ionization potential of the atom, that is, of the order of I_H , we see that for a fast particle ($v \gg v_0$) the classical energy transfer (13.39) is very small compared to the ionization potential, or even to the smallest excitation energy in the atom. But we know that energy must be transferred in definite quantum jumps. A tiny amount of energy like (13.39) simply cannot be absorbed by the atom. We might argue that only if our classical formula (13.2) gives an energy transfer *large* compared to typical atomic excitation energies would we expect it to be correct. This would set quite a different upper limit on the impact parameters. Fortunately the classical result can be applied in a statistical sense if we reinterpret its meaning. Quantum considerations show that the classical result of the transfer of a small amount of energy in every collision is incorrect. But if we consider a large number of collisions, we find that on the average a small amount of energy is transferred. It is not transferred in every collision, however. In most collisions no energy is transferred. But in a few collisions an appreciable excitation occurs, yielding a

small average value over many collisions. In this statistical sense the quantum mechanism for discrete energy transfers and the classical process with a continuum of possible energy transfers can be reconciled. The detailed numerical agreement for the averages (but not for the individual amounts) stems from the quantum-mechanical definitions of the oscillator strengths f_i and resonant frequencies ω_i .

The other important quantum modification arises from the wave nature of the particles. The uncertainty principle sets certain limits on the range of validity of classical orbit considerations. If we try to construct wave packets to give approximate meaning to a classical trajectory, we know that the path can be defined only to within an uncertainty $\Delta x \geq \hbar/p$. For impact parameters b less than this uncertainty, classical concepts fail. Since the wave nature of the particles implies a smearing out in some sense over distances of the order of Δx , we anticipate that the correct quantum-mechanical energy loss will correspond to much smaller energy transfers than given by (13.2) for $b < \Delta x$. Thus $\Delta x \sim \hbar/p$ is a quantum analog of the minimum impact parameter (13.6). In the collision of two particles each one has a wave nature. For a given relative velocity the limiting uncertainty will come from the lighter of the two. For a heavy incident particle colliding with an electron, the momentum of the electron in the coordinate frame where the incident particle is at rest (almost the cm frame) is $p' = \gamma mv$, where m is the mass of the electron. Therefore the quantum-mechanical minimum impact parameter is

$$b_{\min}^{(q)} = \frac{\hbar}{\gamma mv} \quad (13.40)$$

For electrons incident on electrons we must take more care and consider the cm momentum for equal masses. Then for electrons we obtain the minimum impact parameter,

$$[b_{\min}^{(q)}]_{\text{electrons}} = \frac{\hbar}{mc} \sqrt{\frac{2}{\gamma - 1}} \quad (13.41)$$

In a given situation the larger of the two minimum impact parameters (13.6) and (13.40) must be used to define argument B (13.14) of the logarithm in dE/dx . The ratio of the classical to quantum value of b_{\min} is

$$\eta = \frac{ze^2}{\hbar v} \quad (13.42)$$

If $\eta > 1$, the classical Bohr formula must be used. We see that this occurs for slow, highly charged, incident particles, in accord with observation. If $\eta < 1$, the quantum minimum impact parameter is larger than the classical one. Then quantum modifications appear in the energy-loss formula. The argument of the logarithm in (13.13) becomes

$$B_q = \frac{b_{\max}}{b_{\min}^{(q)}} = \eta B = \frac{\gamma^2 mv^2}{\hbar \langle \omega \rangle} \quad (13.43)$$

Equation (13.13) with the quantum-mechanical B_q (13.43) in the logarithm is a good approximation to a quantum-theoretical result of Bethe (1930). Bethe's formula, including the effects of close collisions, is

$$\frac{dE_q}{dx} = 4\pi NZ \frac{z^2 e^4}{mv^2} \left[\ln \left(\frac{2\gamma^2 mv^2}{\hbar\langle\omega\rangle} \right) - \frac{v^2}{c^2} \right] \quad (13.44)$$

Apart from the small correction term $-v^2/c^2$ and a factor of 2 in the argument of the logarithm, this is just our approximate expression.

For electrons the quantum effects embodied in (13.41) lead to a modified quantum-mechanical argument for the logarithm:

$$B_{ei} = (\gamma - 1) \sqrt{\frac{\gamma + 1}{2}} \frac{mc^2}{\hbar\langle\omega\rangle} \rightarrow \frac{\gamma^{3/2}}{\sqrt{2}} \frac{mc^2}{\hbar\langle\omega\rangle} \quad (13.45)$$

where the last expression is valid at high energies. Even though there are other quantum effects for electrons, such as spin and exchange effects, the dominant modifications are included in (13.45).

The general behavior of both the classical and quantum-mechanical energy-loss formulas is shown in Fig. 13.4. At low energies, the main energy variation is as v^{-2} , since the logarithm changes slowly. But at high energies where $v \rightarrow c$ the variation is upwards again, going as $\ln \gamma$ for $\gamma \gg 1$. Bethe's formula is in good agreement with experiment for all fast particles with $\eta < 1$, provided the energy is not too high (see the next section).

It is worth while to note the physical origins of the two powers of γ which appear in B_c (13.37) and B_q (13.43). One power of γ comes from the increase of the maximum energy (13.5) which can be transferred in a head-on collision, making $b_{\min} \propto \gamma^{-1}$ in (13.6) or (13.40). The other power comes from the

Fig. 13.4 Energy loss as a function of kinetic energy.

relativistic change in shape of the electromagnetic fields (11.152) of a fast particle with the consequent shortening of the collision time (11.153) and increase of b_{\max} (13.9). The fields are effective in transferring energy at larger distances for a relativistic particle than for a nonrelativistic one.

Sometimes it is of interest to know the energy loss per unit distance due to collisions in which less than some definite amount ϵ of energy is transferred per collision. In photographic emulsions, for example, ejected electrons of more than about 10 keV energy have a range greater than the average linear dimensions of the silver bromide grains. Consequently the energy dissipated in blackening of the grains corresponds to collisions where the energy transfer is less than about 10 keV. Classically, the desired energy-loss formula can be obtained from the Bohr formula (13.35) with a minimum impact parameter $b_{\min}(\epsilon)$ chosen so that (13.2) is equal to ϵ . Thus

$$b_{\min}(\epsilon) = \frac{2ze^2}{v(2m\epsilon)^{1/2}}$$

This leads to a formula of the form of (13.36), but with an argument in the logarithm,

$$B_c(\epsilon) = \frac{1.123\gamma v^2(2m\epsilon)^{1/2}}{2ze^2\langle\omega\rangle}$$

Since quantum-mechanical energy-loss formulas are obtained from classical ones by the replacement [see (13.43)],

$$B_q = \eta B_c = \frac{ze^2}{\hbar v} B_c$$

we expect that the quantum-mechanical formula for energy-loss per unit distance due to collisions with energy transfer less than ϵ will be

$$\frac{dE_q}{dx}(\epsilon) = 4\pi NZ \frac{z^2 e^4}{mv^2} \left[\ln B_q(\epsilon) - \frac{v^2}{2c^2} \right] \quad (13.46)$$

where

$$B_q(\epsilon) = \lambda \frac{\gamma v(2m\epsilon)^{1/2}}{\hbar\langle\omega\rangle} \quad (13.47)$$

The constant λ is a numerical factor of the order of unity that cannot be determined without detailed quantum-mechanical calculations. Bethe's calculations (1930) give the value $\lambda = 1$. The quantum-mechanical $B_q(\epsilon)$ can be written as

$$B_q(\epsilon) = \frac{b_{\max}}{b_{\min}^{(q)}(\epsilon)} \quad (13.48)$$

where b_{\max} is given by (13.9), and the minimum impact parameter is

$$b_{\min}^{(q)}(\epsilon) \approx \frac{\hbar}{\Delta p} \approx \frac{\hbar}{(2m\epsilon)^{1/2}} \quad (13.49)$$

The implication of this formula is that the classical trajectory must be ill defined by an amount at least as great as (13.49) in order that the uncertainty in transverse momentum Δp be less than the momentum transfer in the collision. Otherwise we would be unable to be certain that an energy transfer of less than ϵ had actually occurred. Hence (13.49) forms a natural quantum-mechanical lower limit on the classical orbit picture in this case.

The expressions for dE/dx obtained so far represent the *average* energy loss per unit distance by a particle traversing matter. Since the number of collisions per unit distance is finite, even if large, and the spectrum of possible energy losses in individual collisions is wide, there will be fluctuations around the average. These fluctuations produce straggling in energy or range for a particle traversing a certain thickness of matter. If the number of collisions is large enough and the energy loss not too great, the final energy of the particle will be distributed in a Gaussian fashion about the mean. The width of the Gaussian can be estimated as follows. In analogy with (13.11) we define the mean square energy loss per unit distance as

$$\frac{dE^2}{dx} = 2\pi NZ \int_{b_{\min}}^{b_{\max}} [\Delta E(b)]^2 b \, db$$

with $\Delta E(b)$ given by (13.2). Provided $b_{\min} \ll b_{\max}$, this becomes

$$\frac{dE^2}{dx} = 4\pi NZ \frac{z^2 e^4}{mv^2} \left[\gamma^2 mv^2 \left(1 - \frac{\beta^2}{2} \right) \right] \quad (13.50)$$

The term $-\beta^2/2$ has been added by hand to make the expression correct relativistically. The collisions contributing most importantly to dE^2/dx are close collisions. For such collisions, involving large deflections of the electron in the rest frame of the incident particle, there is a spin-dependent relativistic correction that modifies the result into the form stated.

For a particle of initial energy E_0 that traverses a thickness x of absorber and emerges with a mean energy \bar{E} , it can be shown (see, for example, *Bohr*, Section 2.3) that the mean square deviation in energy is

$$\Omega^2 = x \frac{dE^2}{dx} \quad (13.51)$$

where it is assumed that $(E_0 - \bar{E})/E_0$ is small so that it is sufficient to evaluate (13.50) at $E = E_0$. The distribution in energy will then be approximately

$$P(E_0, E, x) \approx \frac{1}{\sqrt{2\pi} \Omega} e^{-(E - \bar{E})^2 / 2\Omega^2} \quad (13.52)$$

This result holds provided $\Omega \ll \bar{E}$ and $\Omega \ll (E_0 - \bar{E})$, and also $\Omega \gg \Delta E_{\max} \approx 2\gamma^2 mv^2$. For very relativistic particles the last condition will ultimately fail. Then the distribution of energies is not Gaussian, but is described by the Landau curve. The interested reader can consult the references given at the end of the chapter for further details.

13.4 Density Effect in Collision Energy Loss

For particles which are not too relativistic the observed energy loss is given accurately by (13.44) [or by (13.36) if $\eta > 1$] for all kinds of particles in all types of media. For ultrarelativistic particles, however, the observed energy loss is less than predicted by (13.44), especially for dense substances. In terms of Fig. 13.4 of (dE/dx) , the observed energy loss increases beyond the minimum with a slope of roughly one-half that of the theoretical curve, corresponding to only one power of γ in the argument of the logarithm in (13.44) instead of two. In photographic emulsions the energy loss, as measured from grain densities, barely increases above the minimum to a plateau extending to the highest known energies. This again corresponds to a reduction of one power of γ , this time in $B_q(\epsilon)$ (13.47).

This reduction in energy loss, known as the density effect, was first treated theoretically by Fermi (1940). In our discussion so far we have tacitly made one assumption that is not valid in dense substances. We have assumed that it is legitimate to calculate the effect of the incident particle's fields on one electron in one atom at a time, and then sum up incoherently the energy transfers to all the electrons in all the atoms with $b_{\min} < b < b_{\max}$. Now b_{\max} is very large compared to atomic dimensions, especially for large γ . Consequently in dense media there are many atoms lying between the incident particle's trajectory and the typical atom in question if b is comparable to b_{\max} . These atoms, influenced themselves by the fast particle's fields, will produce perturbing fields at the chosen atom's position, modifying its response to the fields of the fast particle. Said in another way, in dense media the dielectric polarization of the material alters the particle's fields from their free-space values to those characteristic of macroscopic fields in a dielectric. This modification of the fields due to polarization of the medium must be taken into account in calculating the energy transferred in distant collisions. For close collisions the incident particle interacts with only one atom at a time. Then the free-particle calculation without polarization effects will apply. The dividing impact parameter between close and distant collisions is of the order of atomic dimensions. Since the joining of two logarithms is involved in calculating the sum, the dividing value of b need not be specified with great precision.

We will determine the energy loss in distant collisions ($b \geq a$), assuming that the fields in the medium can be calculated in the continuum approximation of a macroscopic dielectric constant $\epsilon(\omega)$. If a is of the order of atomic dimensions, this approximation will not be good for the closest of the distant collisions, but will be valid for the great bulk of the collisions.

The problem of finding the electric field in the medium due to the incident fast particle moving with constant velocity can be solved most readily by Fourier transforms. If the potentials $A_\mu(x)$ and source density $J_\mu(x)$ are transformed in

space and time according to the general rule,

$$F(\mathbf{x}, t) = \frac{1}{(2\pi)^2} \int d^3k \int d\omega F(\mathbf{k}, \omega) e^{i\mathbf{k}\cdot\mathbf{x} - i\omega t} \quad (13.53)$$

then the transformed wave equations become

$$\left. \begin{aligned} \left[k^2 - \frac{\omega^2}{c^2} \epsilon(\omega) \right] \Phi(\mathbf{k}, \omega) &= \frac{4\pi}{\epsilon(\omega)} \rho(\mathbf{k}, \omega) \\ \left[k^2 - \frac{\omega^2}{c^2} \epsilon(\omega) \right] \mathbf{A}(\mathbf{k}, \omega) &= \frac{4\pi}{c} \mathbf{J}(\mathbf{k}, \omega) \end{aligned} \right\} \quad (13.54)$$

The dielectric constant $\epsilon(\omega)$ appears characteristically in positions dictated by the presence of \mathbf{D} in the Maxwell equations. The Fourier transforms of

$$\left. \begin{aligned} \rho(\mathbf{x}, t) &= ze \delta(\mathbf{x} - \mathbf{v}t) \\ \mathbf{J}(\mathbf{x}, t) &= \mathbf{v} \rho(\mathbf{x}, t) \end{aligned} \right\} \quad (13.55)$$

are readily found to be

$$\left. \begin{aligned} \rho(\mathbf{k}, \omega) &= \frac{ze}{2\pi} \delta(\omega - \mathbf{k} \cdot \mathbf{v}) \\ \mathbf{J}(\mathbf{k}, \omega) &= \mathbf{v} \rho(\mathbf{k}, \omega) \end{aligned} \right\} \quad (13.56)$$

From (13.54) we see that the Fourier transforms of the potentials are

$$\left. \begin{aligned} \Phi(\mathbf{k}, \omega) &= \frac{2ze}{\epsilon(\omega)} \cdot \frac{\delta(\omega - \mathbf{k} \cdot \mathbf{v})}{k^2 - \frac{\omega^2}{c^2} \epsilon(\omega)} \\ \mathbf{A}(\mathbf{k}, \omega) &= \epsilon(\omega) \frac{\mathbf{v}}{c} \Phi(\mathbf{k}, \omega) \end{aligned} \right\} \quad (13.57)$$

From the definitions of the electromagnetic fields in terms of the potentials we obtain their Fourier transforms:

$$\left. \begin{aligned} \mathbf{E}(\mathbf{k}, \omega) &= i \left[\frac{\omega \epsilon(\omega)}{c} \frac{\mathbf{v}}{c} - \mathbf{k} \right] \Phi(\mathbf{k}, \omega) \\ \mathbf{B}(\mathbf{k}, \omega) &= i \epsilon(\omega) \mathbf{k} \times \frac{\mathbf{v}}{c} \Phi(\mathbf{k}, \omega) \end{aligned} \right\} \quad (13.58)$$

In calculating the energy loss it is apparent from (13.23) that we want the Fourier transform in time of the electromagnetic fields at a perpendicular distance b from the path of the particle moving along the x axis. Thus the required electric field is

$$\mathbf{E}(\omega) = \frac{1}{(2\pi)^{3/2}} \int d^3k \mathbf{E}(\mathbf{k}, \omega) e^{ibk_z} \quad (13.59)$$

where the observation point has coordinates $(0, b, 0)$. To illustrate the determination of $\mathbf{E}(\omega)$ we consider the calculation of $E_1(\omega)$, the component of \mathbf{E} parallel to \mathbf{v} . Inserting the explicit forms from (13.57) and (13.58), we obtain

$$E_1(\omega) = \frac{2ize}{\epsilon(\omega)} \frac{1}{(2\pi)^{3/2}} \int d^3k e^{ik_2} \left[\frac{\omega \epsilon(\omega) v}{c^2} - k_1 \right] \frac{\delta(\omega - vk_1)}{k^2 - \frac{\omega^2}{c^2} \epsilon(\omega)} \quad (13.60)$$

The integral over dk_1 can be done immediately. Then

$$E_1(\omega) = -\frac{2ize\omega}{(2\pi)^{3/2}v^2} \left[\frac{1}{\epsilon(\omega)} - \beta^2 \right] \int_{-\infty}^{\infty} dk_2 e^{ik_2} \int_{-\infty}^{\infty} \frac{dk_3}{k_2^2 + k_3^2 + \lambda^2}$$

where

$$\lambda^2 = \frac{\omega^2}{v^2} - \frac{\omega^2}{c^2} \epsilon(\omega) = \frac{\omega^2}{v^2} [1 - \beta^2 \epsilon(\omega)] \quad (13.61)$$

The integral over dk_3 has the value $\pi/(\lambda^2 + k_2^2)^{1/2}$, so that $E_1(\omega)$ can be written

$$E_1(\omega) = -\frac{ize\omega}{\sqrt{2\pi}v^2} \left[\frac{1}{\epsilon(\omega)} - \beta^2 \right] \int_{-\infty}^{\infty} \frac{e^{ik_2}}{(\lambda^2 + k_2^2)^{1/2}} dk_2 \quad (13.62)$$

The remaining integral is of the same general structure as (13.28). The result is

$$E_1(\omega) = -\frac{ize\omega}{v^2} \left(\frac{2}{\pi} \right)^{1/2} \left[\frac{1}{\epsilon(\omega)} - \beta^2 \right] K_0(\lambda b) \quad (13.63)$$

where the square root of (13.62) is chosen so that λ lies in the fourth quadrant. A similar calculation yields the other fields:

$$\left. \begin{aligned} E_2(\omega) &= \frac{ze}{v} \left(\frac{2}{\pi} \right)^{1/2} \frac{\lambda}{\epsilon(\omega)} K_1(\lambda b) \\ B_3(\omega) &= \epsilon(\omega) \beta E_2(\omega) \end{aligned} \right\} \quad (13.64)$$

In the limit $\epsilon(\omega) \rightarrow 1$ it is easily seen that fields (13.63) and (13.64) reduce to the earlier results (13.30) and (13.29).

To find the energy transferred to the atom at impact parameter b we merely write down the generalization of (13.23):

$$\Delta E(b) = 2e \sum_j f_j \operatorname{Re} \int_0^{\infty} i\omega \mathbf{x}_j(\omega) \cdot \mathbf{E}^*(\omega) d\omega$$

where $\mathbf{x}_j(\omega)$ is the amplitude of the j th type of electron in the atom. Rather than use (13.19) for $\mathbf{x}_j(\omega)$ we express the sum of dipole moments in terms of the molecular polarizability and so the dielectric constant:

$$-e \sum_j f_j \mathbf{x}_j(\omega) = \frac{1}{4\pi N} [\epsilon(\omega) - 1] \mathbf{E}(\omega)$$

where N is the number of atoms per unit volume. Then the energy transfer can

be written

$$\Delta E(b) = \frac{1}{2\pi N} \operatorname{Re} \int_0^\infty -i\omega \epsilon(\omega) |\mathbf{E}(\omega)|^2 d\omega \quad (13.65)$$

The energy loss per unit distance in collisions with impact parameter $b \geq a$ is evidently

$$\left(\frac{dE}{dx} \right)_{b>a} = 2\pi N \int_a^\infty \Delta E(b) b db \quad (13.66)$$

If fields (13.63) and (13.64) are inserted into (13.65) and (13.66), we find, after some calculation, the expression due to Fermi,

$$\left(\frac{dE}{dx} \right)_{b>a} = \frac{2}{\pi} \frac{(ze)^2}{v^2} \operatorname{Re} \int_0^\infty i\omega \lambda^* a K_1(\lambda^* a) K_0(\lambda a) \left(\frac{1}{\epsilon(\omega)} - \beta^2 \right) d\omega \quad (13.67)$$

where λ is given by (13.61). This result can be obtained more elegantly by calculating the electromagnetic energy flow through a cylinder of radius a around the path of the incident particle. By conservation of energy this is the energy lost per unit time by the incident particle. Thus

$$\left(\frac{dE}{dx} \right)_{b>a} = \frac{1}{v} \frac{dE}{dt} = -\frac{c}{4\pi v} \int_{-\infty}^\infty 2\pi a B_3 E_1 dx$$

The integral over dx at one instant of time is equivalent to an integral at one point on the cylinder over all time. Using $dx = v dt$, we have

$$\left(\frac{dE}{dx} \right)_{b>a} = -\frac{ca}{2} \int_{-\infty}^\infty B_3(t) E_1(t) dt$$

In the standard way this can be converted into a frequency integral,

$$\left(\frac{dE}{dx} \right)_{b>a} = -ca \operatorname{Re} \int_0^\infty B_3^*(\omega) E_1(\omega) d\omega \quad (13.68)$$

With fields (13.63) and (13.64) this gives the Fermi result (13.67).

The Fermi expression (13.67) bears little resemblance to our previous results for energy loss, such as (13.35). But under conditions where polarization effects are unimportant it yields the same results as before. For example, for non-relativistic particles ($\beta \ll 1$) it is clear from (13.61) that $\lambda \approx \omega/v$, independent of $\epsilon(\omega)$. Then in (13.67) the modified Bessel functions are real. Only the imaginary part of $1/\epsilon(\omega)$ contributes to the integral. If we neglect the polarization correction of Section 4.5 to the internal field at an atom, the dielectric constant can be written

$$\epsilon(\omega) \approx 1 + \frac{4\pi N e^2}{m} \sum_j \frac{f_j}{\omega_j^2 - \omega^2 - i\omega\Gamma_j} \quad (13.69)$$

where we have used the dipole moment expression (13.19). Assuming that the second term is small, the imaginary part of $1/\epsilon(\omega)$ can be readily calculated and substituted into (13.67). Then the integral over $d\omega$ can be performed in the same approximation as used in (13.24)–(13.26) to yield the nonrelativistic form of (13.35). If the departure of λ from $\omega/\gamma v$ is neglected, but no other approximations are made, then (13.67) yields precisely the Bohr result (13.35).

The density effect evidently comes from the presence of complex arguments in the modified Bessel functions, corresponding to taking into account $\epsilon(\omega)$ in (13.61). Since $\epsilon(\omega)$ there is multiplied by β^2 , it is clear that the density effect can be really important only at high energies. The detailed calculations for all energies with some explicit expression such as (13.69) for $\epsilon(\omega)$ are quite complicated and not particularly informative. We will content ourselves with the extreme relativistic limit ($\beta \approx 1$). Furthermore, since the important frequencies in the integral over $d\omega$ are optical frequencies and the radius a is of the order of atomic dimensions, $|\lambda a| \sim (\omega a/c) \ll 1$. Consequently we can approximate the Bessel functions by their small argument limits (3.103). Then in the relativistic limit the Fermi expression (13.67) is

$$\left(\frac{dE}{dx}\right)_{b>a} \approx \frac{2}{\pi} \frac{(ze)^2}{c^2} \operatorname{Re} \int_0^\infty i\omega \left(\frac{1}{\epsilon(\omega)} - 1\right) \left\{ \ln \left(\frac{1.123c}{\omega a}\right) - \frac{1}{2} \ln [1 - \epsilon(\omega)] \right\} d\omega \quad (13.70)$$

It is worth while right here to point out that the argument of the second logarithm is actually $[1 - \beta^2 \epsilon(\omega)]$. In the limit $\epsilon = 1$, this log term gives a factor γ in the combined logarithm, corresponding to the old result (13.36). Provided $\epsilon(\omega) \neq 1$, we can write this factor as $[1 - \epsilon(\omega)]$, thereby removing one power of γ from the logarithm, in agreement with experiment.

The integral in (13.70) with $\epsilon(\omega)$ given by (13.69) can be performed most easily by using Cauchy's theorem to change the integral over positive real ω to one over positive imaginary ω , minus one over a quarter circle at infinity. The integral along the imaginary axis gives no contribution. Provided the Γ_j in (13.69) are assumed constant, the result of the integration over the quarter circle can be written in the simple form:

$$\left(\frac{dE}{dx}\right)_{b>a} = \frac{(ze)^2 \omega_p^2}{c^2} \ln \left(\frac{1.123c}{a\omega_p}\right) \quad (13.71)$$

where ω_p is the electronic plasma frequency

$$\omega_p^2 = \frac{4\pi NZe^2}{m} \quad (13.72)$$

The corresponding relativistic expression without the density effect is, from (13.36)

$$\left(\frac{dE}{dx}\right)_{b>a} = \frac{(ze)^2 \omega_p^2}{c^2} \left[\ln \left(\frac{1.123\gamma c}{a\langle\omega\rangle}\right) - \frac{1}{2} \right] \quad (13.73)$$

We see that the density effect produces a simplification in that the asymptotic energy loss no longer depends on the details of atomic structure through $\langle\omega\rangle$ (13.38), but only on the number of electrons per unit volume through ω_p . Two substances having very different atomic structures will produce the same energy loss for ultrarelativistic particles provided their densities are such that the density of electrons is the same in each.

Since there are numerous calculated curves of energy loss based on Bethe's formula (13.44), it is often convenient to tabulate the decrease in energy loss due to the density effect. This is just the difference between (13.73) and (13.71):

$$\lim_{\beta \rightarrow 1} \Delta \left(\frac{dE}{dx} \right) = \frac{(ze)^2 \omega_p^2}{c^2} \left[\ln \left(\frac{\gamma \omega_p}{\langle\omega\rangle} \right) - \frac{1}{2} \right] \quad (13.74)$$

For photographic emulsions, the relevant energy loss is given by (13.46) and (13.47) with $\epsilon \approx 10$ keV. With the density correction applied, this becomes constant at high energies with the value,

$$\frac{dE(\epsilon)}{dx} \rightarrow \frac{(ze)^2 \omega_p^2}{2c^2} \ln \left(\frac{2mc^2 \epsilon}{\hbar^2 \omega_p^2} \right) \quad (13.75)$$

For silver bromide, $\hbar\omega_p \approx 48$ eV. Then for singly charged particles (13.75), divided by the density, has the value of approximately 1.02 MeV-cm²/gm. This energy loss is in good agreement with experiment, and corresponds to an increase above the minimum value of less than 10 per cent. Figure 13.5 shows total energy loss and loss from transfers of less than 10 keV for a typical substance. The dotted curve is the Bethe curve for total energy loss without correction for density effect.

Fig. 13.5 Energy loss, including the density effect. The dotted curve is the total energy loss without density correction. The solid curves have the density effect incorporated, the upper one being the total energy loss and the lower one the energy loss due to individual transfers of less than 10 keV.

13.5 Cherenkov Radiation

The density effect in energy loss is intimately connected to the coherent response of a medium to the passage of a relativistic particle that causes the emission of Cherenkov radiation. They are, in fact, the same phenomenon in different limiting circumstances. The expression (13.67), or better, (13.68), represents the energy lost by the particle into regions a distance greater than $b = a$ away from its path. By varying a we can examine how the energy is deposited throughout the medium. In (13.70) we have considered a to be atomic dimensions and assumed $|\lambda a| \ll 1$. Now we take the opposite limit. If $|\lambda a| \gg 1$, the modified Bessel functions can be approximated by their asymptotic forms. Then the fields (13.63) and (13.64) become

$$\left. \begin{aligned} E_1(\omega, b) &\rightarrow i \frac{ze\omega}{c^2} \left[1 - \frac{1}{\beta^2 \epsilon(\omega)} \right] \frac{e^{-\lambda b}}{\sqrt{\lambda b}} \\ E_2(\omega, b) &\rightarrow \frac{ze}{v\epsilon(\omega)} \sqrt{\frac{\lambda}{b}} e^{-\lambda b} \\ B_3(\omega, b) &\rightarrow \beta \epsilon(\omega) E_2(\omega, b) \end{aligned} \right\} \quad (13.76)$$

The integrand in (13.68) in this limit is

$$(-caB_3^* E_1) \rightarrow \frac{z^2 e^2}{c^2} \left(-i \sqrt{\frac{\lambda^*}{\lambda}} \right) \omega \left[1 - \frac{1}{\beta^2 \epsilon(\omega)} \right] e^{-(\lambda + \lambda^*)a} \quad (13.77)$$

The real part of this expression, integrated over frequencies, gives the energy deposited far from the path of the particle. If λ has a positive real part, as is generally true, the exponential factor in (13.77) will cause the expression to vanish rapidly at large distances. All the energy is deposited near the path. The only occasion when this is not true is when λ is *purely imaginary*. Then the exponential is unity; the expression is independent of a ; *some of the energy escapes to infinity as radiation*. From (13.61) it can be seen that λ can be purely imaginary if $\epsilon(\omega)$ is real (no absorption) and $\beta^2 \epsilon(\omega) > 1$. Actually, mild absorption can be allowed for, but in the interests of simplicity we will assume that $\epsilon(\omega)$ is essentially real from now on. The condition $\beta^2 \epsilon(\omega) > 1$ can be written in the more transparent form,

$$v > \frac{c}{\sqrt{\epsilon(\omega)}} \quad (13.78)$$

This shows that it is necessary for the speed of the particle to be larger than the phase velocity of the electromagnetic fields at frequency ω in order to have emission of Cherenkov radiation of that frequency.

Consideration of the phase of λ as $\beta^2 \epsilon$ changes from less than unity to greater than unity, assuming that $\epsilon(\omega)$ has an infinitesimal positive imaginary part when

$\omega > 0$, shows that

$$\lambda = -i|\lambda|, \quad \text{for } \beta^2\epsilon > 1$$

This means that $(\lambda^*/\lambda)^{1/2} = i$ and (13.77) is real and independent of a . Equation (13.68) then represents the energy radiated as Cherenkov radiation per unit distance along the path of the particle:

$$\left(\frac{dE}{dx}\right)_{\text{rad}} = \frac{(ze)^2}{c^2} \int_{\epsilon(\omega) > (1/\beta^2)} \omega \left(1 - \frac{1}{\beta^2\epsilon(\omega)}\right) d\omega \quad (13.79)$$

The integrand obviously gives the differential spectrum in frequency. This is the Frank-Tamm result, first published in 1937 in an explanation of the radiation observed by Cherenkov in 1934. The radiation is evidently not emitted uniformly in frequency. It tends to be emitted in bands situated somewhat below regions of anomalous dispersion, where $\epsilon(\omega) > \beta^{-2}$, as indicated in Fig. 13.6. Of course, if $\beta \approx 1$ the regions where $\epsilon(\omega) > \beta^{-2}$ may be quite extensive.

Another characteristic feature of Cherenkov radiation is its angle of emission. At large distances from the path the fields become transverse radiation fields. The direction of propagation is given by $\mathbf{E} \times \mathbf{B}$. As shown in Fig. 13.7, the angle θ_C of emission of Cherenkov radiation relative to the velocity of the particle is given by

$$\tan \theta_C = -\frac{E_1}{E_2} \quad (13.80)$$

From the far fields (13.76) we find

$$\cos \theta_C = \frac{1}{\beta\sqrt{\epsilon(\omega)}} \quad (13.81)$$

The criterion $\beta^2\epsilon > 1$ can now be rephrased as the requirement that the emission angle θ_C be a physical angle with cosine less than unity. In passing we note from Fig. 13.7 that Cherenkov radiation is completely linearly polarized in the plane containing the direction of observation and the path of the particle.

Fig. 13.6 Cherenkov band. Radiation is emitted only in shaded frequency range where $\epsilon(\omega) > \beta^{-2}$.

Fig. 13.7

The emission angle θ_c can be interpreted qualitatively in terms of a “shock” wave front akin to the bow shock of a boat in water or the shock front accompanying supersonic flight. In Fig. 13.8 are sketched two sets of successive spherical wavelets moving out with speed $c/\sqrt{\epsilon}$ from successive instantaneous positions of a particle moving with constant velocity v . On the left v is assumed to be less than, and on the right greater than, $c/\sqrt{\epsilon}$. For $v > c/\sqrt{\epsilon}$ the wavelets interfere so as to produce a “shock” front or wake behind the particle, the angle of which is readily seen to be the complement of θ_c . An observer at rest sees a wave front moving in the direction of θ_c .

The qualitative behavior shown in Fig. 13.8 can be given quantitative treatment by examining the potentials $\Phi(\mathbf{x}, t)$ or $\mathbf{A}(\mathbf{x}, t)$ constructed from (13.57) with (13.53). For example, the vector potential takes the form,

$$\mathbf{A}(\mathbf{x}, t) = \frac{2ze}{(2\pi)^2} \boldsymbol{\beta} \int d^3k \frac{e^{ik_1(x-vt)} e^{i\mathbf{k}_\perp \cdot \boldsymbol{\rho}}}{k_1^2(1-\beta^2\epsilon) + k_\perp^2}$$

where $\epsilon = \epsilon(k_1 v)$, while $\boldsymbol{\rho}$ and \mathbf{k}_\perp are transverse coordinates. With the unrealistic, but tractable, approximation that ϵ is a constant the integral can be done in closed form. In the Cherenkov regime ($\beta^2\epsilon > 1$) the denominator has poles on the path of integration. Choosing the contour for the k_1 integration so that the potential vanishes for points ahead of the particle ($x - vt > 0$), the result is found to be

$$\mathbf{A}(\mathbf{x}, t) = \boldsymbol{\beta} \frac{2ze}{\sqrt{(x-vt)^2 - (\beta^2\epsilon - 1)\rho^2}} \quad (13.82)$$

inside the Cherenkov cone and zero outside. Note that \mathbf{A} is singular along the shock front, as suggested by the wavelets in Fig. 13.8. The expression (13.82) can only be taken as indicative. The dielectric constant does vary with $\omega = k_1 v$. This functional dependence will remove the mathematical singularity in (13.82).

The properties of Cherenkov radiation can be utilized to measure velocities of fast particles. If the particles of a given velocity pass through a medium of known dielectric constant ϵ , the light is emitted at the Cherenkov angle (13.81). Thus a

Fig. 13.8 Cherenkov radiation. Spherical wavelets of fields of a particle traveling less than and greater than, the velocity of light in the medium. For $v > c/\sqrt{\epsilon}$, an electromagnetic “shock” wave appears, moving in the direction given by the Cherenkov angle θ_C .

measurement of the angle allows determination of the velocity. Since the dielectric constant of a medium in general varies with frequency, light of different colors is emitted at somewhat different angles. Narrow band filters may be employed to select a small interval of frequency and so improve the precision of velocity measurement. For very fast particles ($\beta \approx 1$) a gas may be used to provide a dielectric constant differing only slightly from unity and having $(\epsilon - 1)$ variable over wide limits by varying the gas pressure. Counting devices using Cherenkov radiation are employed extensively in high-energy physics, as instruments for velocity measurements, as mass analyzers when combined with momentum analysis, and as discriminators against unwanted slow particles.

13.6 Energy Loss in an Electronic Plasma

The loss of energy by a nonrelativistic particle passing through a plasma can be treated in a manner similar to the density effect for a relativistic particle. As was discussed in Section 10.9, the length scale in a plasma is divided into two regions. For dimensions large compared to the Debye screening distance k_D^{-1} (10.91), the plasma acts as a continuous medium in which the charged particles participate in collective behavior such as plasma oscillations. For dimensions small compared to k_D^{-1} , individual-particle behavior dominates and the particles interact by the two-body screened potential (10.98). This means that in

calculating energy loss the Debye screening distance plays the same role here as the atomic dimension a played in the density-effect calculation. For close collisions collective effects can be ignored, and the two-body screened potential can be used to evaluate this contribution to the energy loss. This is left as an exercise for the reader (Problem 13.3). For the distant collisions at impact parameters $bk_D > 1$ the collective effects can be calculated by utilizing Fermi's formula (13.67) with an appropriate dielectric constant for a plasma. The loss in distant collisions corresponds to the excitation of plasma oscillations in the medium.

For a nonrelativistic particle (13.67) yields the following expression for the energy loss to distances $b > k_D^{-1}$:

$$\left(\frac{dE}{dx}\right)_{k_D b > 1} \approx \frac{2}{\pi} \frac{(ze)^2}{v^2} \operatorname{Re} \int_0^\infty \frac{i\omega}{\epsilon(\omega)} \left[\frac{\omega}{k_D v} K_1\left(\frac{\omega}{k_D v}\right) K_0\left(\frac{\omega}{k_D v}\right) \right] d\omega \quad (13.83)$$

Since the important frequencies in the integral turn out to be $\omega \sim \omega_p$, the relevant argument of the Bessel function is

$$\frac{\omega_p}{k_D v} = \frac{\langle u^2 \rangle^{1/2}}{v} \quad (13.84)$$

For particles incident with velocities v less than thermal velocities this argument is large compared to unity. Because of the exponential fall-off of the Bessel functions for large argument, the energy loss in exciting plasma oscillations by such particles is negligible. Whatever energy is lost is in close binary collisions. If the velocity is comparable with or greater than thermal speeds, then the particle can lose appreciable amounts of energy in exciting collective oscillations. It is evident that this energy of oscillation is deposited in the neighborhood of the path of the particle, out to distances of the order of $(v/\langle u^2 \rangle^{1/2})k_D^{-1}$.

For a particle moving rapidly compared to thermal speeds we may use the familiar small argument forms for the modified Bessel functions. Then (13.83) becomes

$$\left(\frac{dE}{dx}\right)_{k_D b > 1} \approx \frac{2}{\pi} \frac{(ze)^2}{v^2} \int_0^\infty \operatorname{Re} \left(\frac{i\omega}{\epsilon(\omega)} \right) \ln \left(\frac{1.123 k_D v}{\omega} \right) d\omega \quad (13.85)$$

We shall take the simple dielectric constant (7.59), augmented by some damping:

$$\epsilon(\omega) = 1 - \frac{\omega_p^2}{\omega^2 + i\omega\Gamma} \quad (13.86)$$

The damping constant Γ will be assumed small compared to ω_p . The necessary combination,

$$\operatorname{Re} \left(\frac{i\omega}{\epsilon(\omega)} \right) = \omega_p^2 \frac{\omega^2 \Gamma}{(\omega^2 - \omega_p^2)^2 + \omega^2 \Gamma^2}$$

has the standard resonant character seen in (13.24), for example. In the limit $\Gamma \ll \omega_p$ the integral in (13.85) leads to the simple result,

$$\left(\frac{dE}{dx}\right)_{k_D b > 1} \simeq \frac{(ze)^2}{v^2} \omega_p^2 \ln \left(\frac{1.123 k_D v}{\omega_p} \right) \quad (13.87)$$

This can be combined with the results of Problem 13.3 to give an expression for the total energy loss of a particle passing through a plasma:

$$\begin{aligned} \frac{dE}{dx} &= \left(\frac{dE}{dx}\right)_{k_D b < 1} + \left(\frac{dE}{dx}\right)_{k_D b > 1} \\ &\simeq \frac{(ze)^2}{v^2} \omega_p^2 \ln \left(\frac{\Lambda v}{\omega_p b_{\min}} \right) \end{aligned} \quad (13.88)$$

where Λ is a number of order unity and b_{\min} is given by the larger of (13.6) and (13.40). The presence of ω_p in the logarithm suggests that the energy losses occur in quantum jumps of $\hbar\omega_p$, in the same way as the mean frequency $\langle\omega\rangle$ in (13.44) is indicative of the typical quantum jumps in atoms. Electrons passing through thin metal foils show this discreteness in their energy loss. The phenomenon can be used to determine the effective plasma frequency in metals.*

13.7 Elastic Scattering of Fast Particles by Atoms

In the preceding sections we have been concerned with the energy loss of particles passing through matter. In these considerations it was assumed that the trajectory of the particle was a straight line. Actually this approximation is not rigorously true. As was discussed in Section 13.1, any momentum transfer between collision partners leads to a deflection in angle. In the introductory remarks at the beginning of the chapter it was pointed out that collisions with electrons determine the energy loss, whereas collisions with atoms determine the scattering. If the screening of the nuclear Coulomb field by the atomic electrons is neglected, a fast particle of momentum $p = \gamma Mv$ and charge ze , passing a heavy nucleus of charge Ze at impact parameter b , will suffer an angular deflection,

$$\theta \simeq \frac{2zZe^2}{pvb} \quad (13.89)$$

according to (13.3).

The differential scattering cross section $d\sigma/d\Omega$ (with dimensions of area per unit solid angle per atom) is defined by the relation,

$$nb \, db \, d\phi = n \frac{d\sigma}{d\Omega} \sin \theta \, d\theta \, d\phi \quad (13.90)$$

* See H. Raether, *Springer Tracts in Modern Physics*, Vol. 38, ed. G. Hohler, Springer-Verlag, Berlin, (1965), pp. 84–157.

where n is the number of particles incident on the atom per unit area per unit time. The left-hand side of (13.90) is the number of particles per unit time incident at azimuthal angles between ϕ and $(\phi + d\phi)$ and impact parameters between b and $(b + db)$. The right-hand side is the number of scattered particles per unit time emerging at polar angles (θ, ϕ) in the element of solid angle $d\Omega = \sin \theta d\theta d\phi$. Equation (13.90) is merely a statement of conservation of particles, since b and θ are functionally related. The classical differential scattering cross section can therefore be written.

$$\frac{d\sigma}{d\Omega} = \frac{b}{\sin \theta} \left| \frac{db}{d\theta} \right| \quad (13.91)$$

The absolute value sign is put on, since db and $d\theta$ can in general have opposite signs, but the cross section is by definition positive definite. If b is a multiple-valued function of θ , then the different contributions must be added in (13.91).

With relation (13.89) between b and θ we find the small-angle nuclear Rutherford scattering cross section per atom,

$$\frac{d\sigma}{d\Omega} \approx \left(\frac{2Ze^2}{pv} \right)^2 \frac{1}{\theta^4} \quad (13.92)$$

We note that the Z electrons in each atom give a contribution Z^{-1} times the nuclear one. Hence the electrons can be ignored, except for their screening action. The small-angle Rutherford law (13.92) for nuclear scattering is found to be true quantum mechanically, independent of the spin nature of the incident particles. At wide angles spin effects enter, but for nonrelativistic particles the classical Rutherford formula,

$$\frac{d\sigma}{d\Omega} = \left(\frac{Ze^2}{2Mv^2} \right)^2 \text{cosec}^4 \frac{\theta}{2} \quad (13.93)$$

which follows from (13.4), holds quantum mechanically as well.

Since most of the scattering occurs for $\theta \ll 1$, and even at $\theta = \pi/2$ the small-angle result (13.92) is within 30 per cent of the Rutherford expression, it is sufficiently accurate to employ (13.92) at all angles for which the unscreened point Coulomb-field description is valid.

Departures from the point Coulomb-field approximation come at large and small angles, corresponding to small and large impact parameters. At large b the screening effects of the atomic electrons cause the potential to fall off more rapidly than $(1/r)$. In the Fermi-Thomas model the potential can be approximated roughly by the form:

$$V(r) \approx \frac{Ze^2}{r} \exp(-r/a) \quad (13.94)$$

where the atomic radius a is

$$a \approx 1.4a_0Z^{-1/3} \quad (13.95)$$

The length $a_0 = \hbar^2/me^2$ is the hydrogenic Bohr radius. For impact parameters of the order of, or greater than, a the rapid decrease of the potential (13.94) will cause the scattering angle to vanish much more rapidly with increasing b than is given by (13.89). This implies that the scattering cross section will flatten off at small angles to a finite value at $\theta=0$, rather than increasing as θ^{-4} . A simple calculation with a cutoff Coulomb potential shows that the cross section has the general form:

$$\frac{d\sigma}{d\Omega} \simeq \left(\frac{2zZe^2}{pv} \right)^2 \frac{1}{(\theta^2 + \theta_{\min}^2)^2} \quad (13.96)$$

where θ_{\min} is a cutoff angle. The minimum angle θ_{\min} below which the cross section departs appreciably from the simple result (13.92) can be determined either classically or quantum mechanically. As with b_{\min} in the energy-loss calculations, the larger of the two angles is the correct one to employ. Classically θ_{\min} can be estimated by putting $b=a$ in (13.89). This gives

$$\theta_{\min}^{(c)} \simeq \frac{2zZe^2}{pva} \quad (13.97)$$

Quantum mechanically, the finite size of the scatterer implies that the approximately classical trajectory must be localized to within $\Delta x < a$; the incident particle must have a minimum uncertainty in transverse momentum $\Delta p \geq \hbar/a$. For collisions in which the momentum transfer (13.1) is large compared to \hbar/a the classical Rutherford formula will apply. But for smaller momentum transfers we expect the quantum-mechanical smearing out to flatten off the cross section. This leads to a quantum mechanical θ_{\min} :

$$\theta_{\min}^{(q)} \simeq \frac{\hbar}{pa} \quad (13.98)$$

We note that the ratio of the classical to quantum-mechanical angles θ_{\min} is $Zze^2/\hbar v$ in agreement with the ratio (13.42) of the classical and quantum values of b_{\min} . For fast particles in all but the highest Z substances ($Zze^2/\hbar v$) is less than unity. Then the quantum value (13.98) will be used for θ_{\min} . With value (13.95) for the screening radius a , (13.98) becomes

$$\theta_{\min}^{(q)} \simeq \frac{Z^{1/3}}{192} \left(\frac{mc}{p} \right) \quad (13.99)$$

where p is the incident momentum ($p = \gamma Mv$), and m is the electronic mass.

At comparatively large angles the cross section departs from (13.92) because of the finite size of the nucleus. For electrons and mu mesons the influence of nuclear size is a purely electromagnetic effect, but for pi mesons, protons, etc., there are specific effects of a nuclear-force nature as well. Since the gross overall effect is to lower the cross section below that predicted by (13.92) for whatever reason, we will consider only the electromagnetic aspect. The charge distribution

of the atomic nucleus can be crudely approximated by a uniform volume distribution inside a sphere of radius R , falling rapidly to zero outside R . This means that the electrostatic potential inside the nucleus is not $1/r$, but rather parabolic in shape with a finite value at $r=0$:

$$V(r) = \begin{cases} \frac{3}{2} \frac{zZe^2}{R} \left(1 - \frac{r^2}{3R^2}\right), & \text{for } r < R \\ \frac{zZe^2}{r}, & \text{for } r > R \end{cases} \quad (13.100)$$

It is a peculiarity of the point-charge Coulomb field that the quantum-mechanical cross section is the classical Rutherford formula. Thus for a point nucleus there is no need to consider a division of the angular region into angles corresponding to impact parameters less than, or greater than, the quantum-mechanical impact parameter $b_{\min}^{(q)}$ (13.40). For a nucleus of finite size, however, the de Broglie wavelength of the incident particle does enter. When we consider wave packets incident on the relatively constant (inside $r=R$) potential (13.100), there will be appreciable departures from the simple formula (13.92). The situation is quite analogous to the diffraction of waves by a spherical object, considered in Chapter 9. The scattering is all confined to angles less than $\sim(\lambda/R)$, where λ is the wavelength (divided by 2π) of the waves involved. For wider angles the wavelets from different parts of the scatterer interfere, causing a rapid decrease in the scattering or perhaps subsidiary maxima and minima. Since the particle wavelength is $\lambda = \hbar/p$, the maximum scattering angle, beyond which the scattering cross section falls significantly below the θ^{-4} law, is

$$\theta_{\max} \simeq \frac{\hbar}{pR} \quad (13.101)$$

Using the simple estimate $R \simeq \frac{1}{2}(e^2/mc^2)A^{1/3} = 1.4A^{1/3} \times 10^{-13}$ cm, this has the numerical value,

$$\theta_{\max} \simeq \frac{274}{A^{1/3}} \left(\frac{mc}{p} \right) \quad (13.102)$$

We note that, for all values of Z and A , $\theta_{\max} \gg \theta_{\min}$. If the incident momentum is so small that $\theta_{\max} \geq 1$, the nuclear size has no appreciable effect on the scattering. For an aluminum target $\theta_{\max} = 1$ when $p \sim 50$ MeV/c, corresponding to ~ 50 MeV, 12 MeV, and 1.3 MeV kinetic energies for electrons, mu mesons, and protons, respectively. Only at higher energies than these are nuclear-size effects important in the scattering. At this momentum value $\theta_{\min}^{(q)} \sim 10^{-4}$ radian.

The general behavior of the cross section is shown in Fig. 13.9. The dotted curve is the small-angle Rutherford approximation (13.92), while the solid curve shows the qualitative behavior of the cross section, including screening and finite nuclear size. The total scattering cross section can be obtained by integrating

Fig. 13.9 Atomic scattering, including effects of electronic screening at small angles and finite nuclear size at large angles.

(13.96) over all solid angle:

$$\sigma = \int \frac{d\sigma}{d\Omega} \sin \theta \, d\theta \, d\phi \approx 2\pi \left(\frac{2zZe^2}{pv} \right)^2 \int_0^\infty \frac{\theta \, d\theta}{(\theta_{\min}^2 + \theta^2)^2} \quad (13.103)$$

This yields

$$\sigma \approx \pi \left(\frac{2zZe^2}{pv} \right)^2 \frac{1}{\theta_{\min}^2} = \pi a^2 \left(\frac{2zZe^2}{\hbar v} \right)^2 \quad (13.104)$$

where the final form is obtained by using $\theta_{\min}^{(a)}$ (13.98). It shows that at high velocities the total cross section can be far smaller than the classical value of geometrical area πa^2 .

13.8 Mean Square Angle of Scattering and the Angular Distribution of Multiple Scattering

Rutherford scattering is confined to very small angles even for a point Coulomb field, and for fast particles θ_{\max} is small compared to unity. Thus there is a very large probability for small-angle scattering. A particle traversing a finite thickness of matter will undergo very many small-angle deflections and will generally emerge at a small angle which is the cumulative statistical superposition of a large number of deflections. Only rarely will the particle be deflected through a large angle; since these events are infrequent, such a particle will have made only one such collision. This circumstance allows us to divide the angular range into two regions—one region at comparatively large angles which contains only the single scatterings, and one region at very small angles which

contains the multiple or compound scatterings. The complete distribution in angle can be approximated by considering the two regions separately. The intermediate region of so-called plural scattering must allow a smooth transition from small to large angles.

The important quantity in the multiple-scattering region, where there is a large succession of small-angle deflections symmetrically distributed about the incident direction, is the mean square angle for a single scattering. This is defined by

$$\langle \theta^2 \rangle = \frac{\int \theta^2 \frac{d\sigma}{d\Omega} d\Omega}{\int \frac{d\sigma}{d\Omega} d\Omega} \quad (13.105)$$

With the approximations of Section 13.7 we obtain

$$\langle \theta^2 \rangle = 2\theta_{\min}^2 \ln \left(\frac{\theta_{\max}}{\theta_{\min}} \right) \quad (13.106)$$

If the quantum value (13.99) of θ_{\min} is used along with θ_{\max} (13.102), then with $A \approx 2Z$, (13.106) has the numerical form:

$$\langle \theta^2 \rangle \approx 4\theta_{\min}^2 \ln (204Z^{-1/3}) \quad (13.107)$$

If nuclear size is unimportant (generally only of interest for electrons, and perhaps other particles at very low energies), θ_{\max} should be put equal to unity in (13.106). Then the argument of the logarithm in (13.107) becomes $\left(\frac{192}{Z^{1/3}} \frac{p}{mc} \right)^{1/2}$, instead of $(204Z^{-1/3})$.

It is often desirable to use the projected angle of scattering θ' , the projection being made on some convenient plane such as the plane of a photographic emulsion or a bubble chamber, as shown in Fig. 13.10. For small angles it is easy to show that

$$\langle \theta'^2 \rangle = \frac{1}{2} \langle \theta^2 \rangle \quad (13.108)$$

In each collision the angular deflections obey the Rutherford formula (13.92) suitably cut off at θ_{\min} and θ_{\max} , with average value zero (when viewed relative to the forward direction, or as a projected angle) and mean square angle $\langle \theta^2 \rangle$ given by (13.106). Since the successive collisions are independent events, the central-limit theorem of statistics can be used to show that for a large number n of such collisions the distribution in angle will be approximately Gaussian around the forward direction with a mean square angle $\langle \Theta^2 \rangle = n \langle \theta^2 \rangle$. The number of collisions occurring as the particle traverses a thickness t of material containing N atoms per unit volume is

$$n = N\sigma t \approx \pi N \left(\frac{2zZe^2}{pv} \right)^2 \frac{t}{\theta_{\min}^2} \quad (13.109)$$

Fig. 13.10

This means that the mean square angle of the Gaussian is

$$\langle \Theta^2 \rangle \approx 2\pi N \left(\frac{2zZe^2}{pv} \right)^2 \ln \left(\frac{\theta_{\max}}{\theta_{\min}} \right) t \quad (13.110)$$

Or, using (13.107) for $\langle \theta^2 \rangle$,

$$\langle \Theta^2 \rangle \approx 4\pi N \left(\frac{2zZe^2}{pv} \right)^2 \ln(204Z^{-1/3}) t \quad (13.111)$$

The mean square angle increases linearly with the thickness t . But for reasonable thicknesses such that the particle does not lose appreciable energy, the Gaussian will still be peaked at very small forward angles.

The multiple-scattering distribution for the projected angle of scattering is

$$P_M(\theta') d\theta' = \frac{1}{\sqrt{\pi \langle \Theta^2 \rangle}} \exp \left(-\frac{\theta'^2}{\langle \Theta^2 \rangle} \right) d\theta' \quad (13.112)$$

where both positive and negative values of θ' are considered. The small-angle Rutherford formula (13.92) can be expressed in terms of the projected angle as

$$\frac{d\sigma}{d\theta'} = \frac{\pi}{2} \left(\frac{2zZe^2}{pv} \right)^2 \frac{1}{\theta'^3} \quad (13.113)$$

This gives a single-scattering distribution for the projected angle:

$$P_S(\theta') d\theta' = N t \frac{d\sigma}{d\theta'} d\theta' = \frac{\pi}{2} N t \left(\frac{2zZe^2}{pv} \right)^2 \frac{d\theta'}{\theta'^3} \quad (13.114)$$

The single-scattering distribution is valid only for angles large compared to $\langle \Theta^2 \rangle^{1/2}$, and contributes a tail to the Gaussian distribution.

If we express angles in terms of the relative projected angle,

$$\alpha = \frac{\theta'}{\langle \Theta^2 \rangle^{1/2}} \quad (13.115)$$

the multiple- and single-scattering distribution can be written

$$P_M(\alpha) d\alpha = \frac{1}{\sqrt{\pi}} e^{-\alpha^2} d\alpha \quad (13.116)$$

$$P_S(\alpha) d\alpha = \frac{1}{8 \ln(204Z^{-1/3})} \frac{d\alpha}{\alpha^3}$$

where (13.111) has been used for $\langle \Theta^2 \rangle$. We note that the relative amounts of multiple and single scatterings are independent of thickness in these units, and depend only on Z . Even this Z dependence is not marked. The factor $8 \ln(204Z^{-1/3})$ has the value 36 for $Z=13$ (aluminum) and the value 31 for $Z=82$ (lead). Figure 13.11 shows the general behavior of the scattering

Fig. 13.11 Multiple and single scattering distributions of projected angle. In the region of plural scattering ($\alpha \sim 2-3$) the dotted curve indicates the smooth transition from the small-angle multiple scattering (approximately Gaussian in shape) to the wide-angle single scattering (proportional to α^{-3}).

distributions as a function of α . The transition from multiple to single scattering occurs in the neighborhood of $\alpha \approx 2.5$. At this point the Gaussian has a value of $1/600$ times its peak value. Thus the single-scattering distribution gives only a very small tail on the multiple-scattering curve.

There are two things which cause departures from the simple behavior shown in Fig. 13.11. The Gaussian shape is the limiting form of the angular distribution for very large n . If the thickness t is such that n (13.109) is not very large (i.e., $n \leq 100$), the distribution follows the single-scattering curve to smaller angles than $\alpha \approx 2.5$, and is somewhat more sharply peaked at zero angle than a Gaussian. On the other hand, if the thickness is great enough, the mean square angle $\langle \theta^2 \rangle$ becomes comparable with the angle θ_{\max} (13.102) which limits the angular width of the single-scattering distribution. For greater thicknesses the multiple-scattering curve extends in angle beyond the single-scattering region, so that there is no single-scattering tail on the distribution (see Problem 13.5).

REFERENCES AND SUGGESTED READING

The problems of the penetration of particles through matter interested Niels Bohr all his life. A lovely presentation of the whole subject, with characteristic emphasis on the interplay of classical and quantum-mechanical effects, appears in his comprehensive review article of 1948:

Bohr.

Numerical tables and graphs of energy-loss data, as well as key formulas, are given by

Rossi, Chapter 2,

Segre, article by H. A. Bethe and J. Ashkin.

See also

U. Fano, *Ann. Rev. Nucl. Sci.* **13**, 1 (1963).

Rossi gives a semiclassical treatment of energy loss and scattering similar to ours. He also considers the question of fluctuations in energy loss, including the Landau-Symon theory.

The density effect on the energy loss by extremely relativistic particles is discussed, with numerous results for different substances in graphical form, by

R. M. Sternheimer, in *Methods of Experimental Physics*, Vol. 5A, *Nuclear Physics*, Part A, eds. L. C. L. Yuan and C. S. Wu, Academic, New York, (1961), pp. 4-55.

Cherenkov radiation is discussed in many places. Its application to particle detectors is described in the book by Yuan and Wu, just mentioned, and also in

D. M. Ritson, ed., *Techniques in High Energy Physics*, Interscience, New York (1961).

For current applications, however, the reader must turn to journals such as *Nuclear Instruments and Methods*.

PROBLEMS

13.1 A heavy particle of charge ze , mass M , and nonrelativistic velocity v collides with a free electron of charge $-e$ and mass m initially at rest. With no approximations, other

than that of nonrelativistic motion and $M \gg m$, show that the energy transferred to the electron in this Coulomb collision, as a function of the impact parameter b , is

$$\Delta E(b) = \frac{2(ze^2)^2}{mv^2} \frac{1}{b^2 + (ze^2/mv^2)^2}$$

13.2 (a) Taking $\hbar\omega = 12\text{Z eV}$ in the quantum-mechanical energy-loss formula, calculate the rate of energy loss (in MeV/cm) in air at N.T.P., aluminum, copper, lead for a proton and a mu meson, each with kinetic energies of 10, 100, 1000 MeV.

(b) Convert your results to energy loss in units of MeV-cm²/gm and compare the values obtained in different materials. Explain why all the energy losses in MeV-cm²/gm are within a factor of 2 of each other, whereas the values in MeV/cm differ greatly.

13.3 Consider the energy loss by close collisions of a fast, but nonrelativistic, heavy particle of charge ze passing through an electronic plasma. Assume that the screened Coulomb interaction (10.98) acts between the electrons and the incident particle.

(a) Show that the energy transfer in a collision at impact parameter b is given approximately by

$$\Delta E(b) = \frac{2(ze^2)^2}{mv^2} k_D^2 K_1^2(k_D b)$$

where m is the electron mass, v is the velocity of the incident particle, and k_D is the Debye wave number (10.99).

(b) Determine the energy loss per unit distance traveled for collisions with impact parameter greater than b_{\min} . Assuming $k_D b_{\min} \ll 1$, show that

$$\left(\frac{dE}{dx}\right)_{k_D b < 1} \approx \frac{(ze)^2}{v^2} \omega_p^2 \ln\left(\frac{1}{1.47 k_D b_{\min}}\right)$$

where b_{\min} is given by the larger of (13.6) and (13.40).

13.4 With the same approximations as were used to discuss multiple scattering, show that the *projected* transverse displacement y (see Fig. 13.10) of an incident particle is described approximately by a Gaussian distribution,

$$P(y) dy = A \exp\left[\frac{-y^2}{2\langle y^2 \rangle}\right] dy$$

where the mean square displacement is $\langle y^2 \rangle = (x^2/6)\langle \Theta^2 \rangle$, x being the thickness of the material traversed and $\langle \Theta^2 \rangle$ the mean square angle of scattering.

13.5 If the finite size of the nucleus is taken into account in the “single-scattering” tail of the multiple-scattering distribution, there is a critical thickness x_c beyond which the single-scattering tail is absent.

(a) Define x_c in a reasonable way and calculate its value (in cm) for aluminum and lead, assuming that the incident particle is relativistic.

(b) For these thicknesses calculate the number of collisions which occur and determine whether the Gaussian approximation is valid.

13.6 Assuming that Plexiglas or Lucite has an index of refraction of 1.50 in the visible region, compute the angle of emission of visible Cherenkov radiation for electrons and protons as a function of their kinetic energies in MeV. Determine how many quanta with wavelengths between 4000 and 6000 angstroms are emitted per centimeter of path in Lucite by a 1-MeV electron, a 500-MeV proton, a 5-GeV proton.

13.7 A particle of charge ze moves along the z axis with constant speed v , passing $z=0$ at $t=0$. The medium through which the particle moves is described by a dielectric constant $\epsilon(\omega)$.

(a) Beginning with the potential $\Phi(\mathbf{k}, \omega)$ of (13.57), show that the potential of frequency ω is given as a function of spatial coordinate \mathbf{x} by

$$\Phi(\omega, \mathbf{x}) = \frac{ze}{v\epsilon(\omega)} \sqrt{\frac{2}{\pi}} K_0\left(\frac{|\omega|\rho}{v} \sqrt{1-\beta^2\epsilon}\right) e^{i\omega z/v}$$

where z and $\rho = \sqrt{x^2 + y^2}$ are the cylindrical coordinates of the observation point.

(b) Assuming that ϵ is independent of frequency and that $\beta^2\epsilon < 1$, take the Fourier transform with respect to ω of the expression in (a) and obtain $\Phi(\mathbf{x}, t)$. Calculate the electric and magnetic fields and compare them to the vacuum fields (11.152). Show that, among other things, the vacuum factor γ is replaced by $\Gamma = (1 - \beta^2\epsilon)^{-1/2}$.

(c) Repeat the calculations of (a) and (b) with $\beta^2\epsilon > 1$. Show that now

$$\Phi(\omega, \mathbf{x}) = \frac{ze}{v\epsilon(\omega)} \sqrt{\frac{\pi}{2}} e^{i\omega z/v} \left[-N_0\left(\frac{|\omega|\rho}{v} \sqrt{\beta^2\epsilon - 1}\right) \pm iJ_0\left(\frac{|\omega|\rho}{v} \sqrt{\beta^2\epsilon - 1}\right) \right]$$

for $\omega \geq 0$. Calculate the remaining Fourier transform to obtain $\Phi(\mathbf{x}, t)$. Relate your answer to the result given in Section 13.5 for $\mathbf{A}(\mathbf{x}, t)$.

13.8 A magnetic monopole with magnetic charge g passes through matter and loses energy by collisions with electrons, just as does a particle with electric charge ze .

(a) In the same approximation as presented in Sections 13.1–13.3, show that the energy loss per unit distance is given approximately by (13.44), but with $ze \rightarrow \beta g$, yielding

$$\left(\frac{dE}{dx}\right)_{\text{magnetic monopole}} \approx 4\pi NZ \frac{g^2 e^2}{mc^2} \ln\left(\frac{2\gamma^2 mv^2}{\hbar\langle\omega\rangle}\right)$$

(b) With the Dirac quantization condition (6.153) determining the magnetic charge, what z value is necessary for an ordinary charged particle in order that it lose energy at relativistic speeds at the same rate as a monopole? Sketch for the magnetic monopole a curve of dE/dx equivalent to Fig. 13.4 and comment on the differences.

14

Radiation By Moving Charges

It is well known that accelerated charges emit electromagnetic radiation. In Chapter 9 we discussed examples of radiation by macroscopic time-varying charge and current densities, which are fundamentally charges in motion. We will return to such problems in Chapter 16 where multipole radiation is treated in a systematic way. But there is a class of radiation phenomena where the source is a moving point charge or a small number of such charges. In these problems it is useful to develop the formalism in such a way that the radiation intensity and polarization are related directly to properties of the charge's trajectory and motion. Of particular interest are the total radiation emitted, the angular distribution of radiation, and its frequency spectrum. For nonrelativistic motion the radiation is described by the well-known Larmor result (see Section 14.2). But for relativistic particles a number of unusual and interesting effects appear. It is these relativistic aspects which we wish to emphasize. In the present chapter a number of general results are derived and applied to examples of charges undergoing prescribed motions, especially in external force fields. The one exception is a discussion of transition radiation, the cooperative phenomenon that occurs when a particle crosses an interface between two media of different dielectric properties. Chapter 15 deals with radiation emitted in atomic or nuclear collisions.

14.1 Liénard-Wiechert Potentials and Fields for a Point Charge

In Section 12.11 it was shown that if there are no incoming fields the 4-vector potential caused by a charged particle in motion is

$$A^{\alpha}(x) = \frac{4\pi}{c} \int d^4x' D_r(x-x') J^{\alpha}(x') \quad (14.1)$$

where $D_r(x-x')$ is the retarded Green function (12.133) and

$$J^\alpha(x') = ec \int d\tau V^\alpha(\tau) \delta^{(4)}[x' - r(\tau)] \quad (14.2)$$

is the charge's 4-vector current, $V^\alpha(\tau)$ its 4-velocity and $r^\alpha(\tau)$ its position. Insertion of the Green function and the current into (14.1) gives, upon integration over d^4x' ,

$$A^\alpha(x) = 2e \int d\tau V^\alpha(\tau) \theta[x_0 - r_0(\tau)] \delta\{[x - r(\tau)]^2\} \quad (14.3)$$

The remaining integral over the charge's proper time gives a contribution only at $\tau = \tau_0$, where τ_0 is defined by the light-cone condition,

$$[x - r(\tau_0)]^2 = 0 \quad (14.4)$$

and the retardation requirement $x_0 > r_0(\tau_0)$. The significance of these conditions is shown diagrammatically in Fig. 14.1. The Green function is different from zero only on the backward light cone of the observation point. The world line of the particle $r(\tau)$ intersects the light cone at only two points, one earlier and one later than x_0 . The earlier point, $r^\alpha(\tau_0)$, is the only part of the path that contributes to the fields at x^α . To evaluate (14.3) we use the rule,

$$\delta[f(x)] = \sum_i \frac{\delta(x - x_i)}{\left| \left(\frac{df}{dx} \right)_{x=x_i} \right|}$$

where the points $x = x_i$ are the zeros of $f(x)$, assumed to be linear. We need

$$\frac{d}{d\tau} [x - r(\tau)]^2 = -2[x - r(\tau)]_\beta V^\beta(\tau) \quad (14.5)$$

Fig. 14.1

evaluated at the one point, $\tau = \tau_0$. The 4-vector potential is therefore

$$A^\alpha(x) = \frac{e V^\alpha(\tau)}{V \cdot [x - r(\tau)]} \Big|_{\tau=\tau_0} \quad (14.6)$$

where τ_0 is defined by (14.4) and the retardation requirement.

The potentials (14.6) are known as the *Liénard-Wiechert potentials*. They are often written in noncovariant, but perhaps more familiar, form as follows. The light-cone constraint (14.4) implies $x_0 - r_0(\tau_0) = |\mathbf{x} - \mathbf{r}(\tau_0)| \equiv R$. Then

$$\begin{aligned} V \cdot (x - r) &= V_0[x_0 - r_0(\tau_0)] - \mathbf{V} \cdot [\mathbf{x} - \mathbf{r}(\tau_0)] \\ &= \gamma c R - \gamma \mathbf{v} \cdot \mathbf{n} R \\ &= \gamma c R (1 - \boldsymbol{\beta} \cdot \mathbf{n}) \end{aligned} \quad (14.7)$$

where \mathbf{n} is a unit vector in the direction of $\mathbf{x} - \mathbf{r}(\tau)$ and $\boldsymbol{\beta} = \mathbf{v}(\tau)/c$. The potentials (14.6) can thus be written

$$\Phi(\mathbf{x}, t) = \left[\frac{e}{(1 - \boldsymbol{\beta} \cdot \mathbf{n}) R} \right]_{\text{ret}}, \quad \mathbf{A}(\mathbf{x}, t) = \left[\frac{e \boldsymbol{\beta}}{(1 - \boldsymbol{\beta} \cdot \mathbf{n}) R} \right]_{\text{ret}} \quad (14.8)$$

The square brackets with subscript “ret” mean that the quantity in the brackets is to be evaluated at the retarded time. $r_0(\tau_0) = x_0 - R$. It is evident that for nonrelativistic motion the potentials reduce to the well-known results.

The electromagnetic fields $F^{\alpha\beta}(x)$ can be calculated directly from (14.6) or (14.8), but it is simpler to return to the integral over $d\tau$, (14.3). In computing $F^{\alpha\beta}$ the differentiation with respect to the observation point x will act on the theta and delta functions. Differentiation of the theta function will give $\delta[x_0 - r_0(\tau)]$ and so constrain the delta function to be $\delta(-R^2)$. There will be no contribution from this differentiation except at $R = 0$. Excluding $R = 0$ from consideration, the derivative $\partial^\alpha A^\beta$ is

$$\partial^\alpha A^\beta = 2e \int d\tau V^\beta(\tau) \theta[x_0 - r_0(\tau)] \partial^\alpha \delta\{[x - r(\tau)]^2\} \quad (14.9)$$

The partial derivative can be written

$$\partial^\alpha \delta[f] = \partial^\alpha f \cdot \frac{d}{df} \delta[f] = \partial^\alpha f \cdot \frac{d\tau}{df} \cdot \frac{d}{d\tau} \delta[f]$$

where $f = [x - r(\tau)]^2$. The indicated differentiation gives

$$\partial^\alpha \delta[f] = -\frac{(x-r)^\alpha}{V \cdot (x-r)} \frac{d}{d\tau} \delta[f]$$

When this is inserted into (14.9) and an integration by parts performed, the result is

$$\partial^\alpha A^\beta = 2e \int d\tau \frac{d}{d\tau} \left[\frac{(x-r)^\alpha V^\beta}{V \cdot (x-r)} \right] \theta[x_0 - r_0(\tau)] \delta\{[x - r(\tau)]^2\} \quad (14.10)$$

In the integration by parts the differentiation of the theta function gives no contribution, as already indicated. The form of (14.10) is the same as (14.3), with $V^\alpha(\tau)$ replaced by the derivative term. The result can thus be read off by substitution from (14.6). The field strength tensor is

$$F^{\alpha\beta} = \frac{e}{V \cdot (x-r)} \frac{d}{d\tau} \left[\frac{(x-r)^\alpha V^\beta - (x-r)^\beta V^\alpha}{V \cdot (x-r)} \right] \quad (14.11)$$

Here r^α and V^α are functions of τ . After differentiation the whole expression is to be evaluated at the retarded proper time τ_0 .

The field strength tensor $F^{\alpha\beta}$ (14.11) is manifestly covariant, but not overly explicit. It is sometimes useful to have the fields \mathbf{E} and \mathbf{B} exhibited as explicit functions of the charge's velocity and acceleration. Some of the ingredients needed to carry out the differentiation in (14.11) are

$$\left. \begin{aligned} (x-r)^\alpha &= (R, R\mathbf{n}), & V^\alpha &= (\gamma c, \gamma c\boldsymbol{\beta}) \\ \frac{dV^\alpha}{d\tau} &= [c\gamma^4 \boldsymbol{\beta} \cdot \dot{\boldsymbol{\beta}}, c\gamma^2 \dot{\boldsymbol{\beta}} + c\gamma^4 \boldsymbol{\beta}(\boldsymbol{\beta} \cdot \dot{\boldsymbol{\beta}})] \\ \frac{d}{d\tau} [V \cdot (x-r)] &= -c^2 + (x-r)_\alpha \frac{dV^\alpha}{d\tau} \end{aligned} \right\} \quad (14.12)$$

where $\dot{\boldsymbol{\beta}} = d\boldsymbol{\beta}/dt$ is the ordinary acceleration, divided by c . When these and (14.7) are employed the fields (14.11) can be written in the inelegant, but perhaps more intuitive, forms,

$$\mathbf{B} = [\mathbf{n} \times \mathbf{E}]_{\text{ret}} \quad (14.13)$$

$$\mathbf{E}(\mathbf{x}, t) = e \left[\frac{\mathbf{n} - \boldsymbol{\beta}}{\gamma^2 (1 - \boldsymbol{\beta} \cdot \mathbf{n})^3 R^2} \right]_{\text{ret}} + \frac{e}{c} \left[\frac{\mathbf{n} \times \{(\mathbf{n} - \boldsymbol{\beta}) \times \dot{\boldsymbol{\beta}}\}}{(1 - \boldsymbol{\beta} \cdot \mathbf{n})^3 R} \right]_{\text{ret}} \quad (14.14)$$

Fields (14.13) and (14.14) divide themselves naturally into "velocity fields," which are independent of acceleration, and "acceleration fields," which depend linearly on $\dot{\boldsymbol{\beta}}$. The velocity fields are essentially static fields falling off as R^{-2} , whereas the acceleration fields are typical radiation fields, both \mathbf{E} and \mathbf{B} being transverse to the radius vector and varying as R^{-1} .

For the special circumstance of a particle in uniform motion the second term in (14.14) is absent. The first term, the velocity field, must be the same as that obtained in Section 11.10 by means of a Lorentz transformation of the static Coulomb field. One way to establish this is to note from (14.11) for $F^{\alpha\beta}$ that if V^α is constant, the field is

$$F^{\alpha\beta} = \frac{ec^2}{[V \cdot (x-r)]^3} \cdot [(x-r)^\alpha V^\beta - (x-r)^\beta V^\alpha] \quad (14.15)$$

in agreement with the third covariant form in Problem 11.15. It may be worthwhile, nevertheless, to make a transformation of the charge's coordinates from its present position (used in Section 11.10) to the retarded position used here in order to demonstrate explicitly how the different appearing expressions,

Fig. 14.2 Present and retarded positions of a charge in uniform motion.

(11.152) and (14.14), are actually the same. The two positions of the charge are shown in Fig. 14.2 as the points P and P' , while O is the observation point. The distance $P'Q$ is $\beta R \cos \theta = \boldsymbol{\beta} \cdot \mathbf{n} R$. Therefore the distance OQ is $(1 - \boldsymbol{\beta} \cdot \mathbf{n})R$. But from the triangles OPQ and $PP'Q$ we have $[(1 - \boldsymbol{\beta} \cdot \mathbf{n})R]^2 = r^2 - (PQ)^2 = r^2 - \beta^2 R^2 \sin^2 \theta$. Then from the triangle OMP' we have $R \sin \theta = b$, so that

$$[(1 - \boldsymbol{\beta} \cdot \mathbf{n})R]^2 = b^2 + v^2 t^2 - \beta^2 b^2 = \frac{1}{\gamma^2} (b^2 + \gamma^2 v^2 t^2) \quad (14.16)$$

The transverse component E_2 from (11.152),

$$E_2 = \frac{e\gamma b}{(b^2 + \gamma^2 v^2 t^2)^{3/2}} \quad (14.17a)$$

can thus be written in terms of the retarded position as

$$E_2 = e \left[\frac{b}{\gamma^2 (1 - \boldsymbol{\beta} \cdot \mathbf{n})^3 R^3} \right]_{\text{ret}} \quad (14.17b)$$

This is just the transverse component of the velocity field in (14.14). The other components of \mathbf{E} and \mathbf{B} come out similarly.

14.2 Total Power Radiated by an Accelerated Charge—Larmor's Formula and Its Relativistic Generalization

If a charge is accelerated but is observed in a reference frame where its velocity is small compared to that of light, then in that coordinate frame the acceleration field in (14.14) reduces to

$$\mathbf{E}_a = \frac{e}{c} \left[\frac{\mathbf{n} \times (\mathbf{n} \times \dot{\boldsymbol{\beta}})}{R} \right]_{\text{ret}} \quad (14.18)$$

Fig. 14.3

The instantaneous energy flux is given by the Poynting vector,

$$\mathbf{S} = \frac{c}{4\pi} \mathbf{E} \times \mathbf{B} = \frac{c}{4\pi} |\mathbf{E}_a|^2 \mathbf{n} \quad (14.19)$$

This means that the power radiated per unit solid angle is*

$$\frac{dP}{d\Omega} = \frac{c}{4\pi} |R\mathbf{E}_a|^2 = \frac{e^2}{4\pi c} |\mathbf{n} \times (\mathbf{n} \times \dot{\mathbf{p}})|^2 \quad (14.20)$$

If Θ is the angle between the acceleration $\dot{\mathbf{v}}$ and \mathbf{n} , as shown in Fig. 14.3, then the power radiated can be written

$$\frac{dP}{d\Omega} = \frac{e^2}{4\pi c^3} |\dot{\mathbf{v}}|^2 \sin^2 \Theta \quad (14.21)$$

This exhibits the characteristic $\sin^2 \Theta$ angular dependence which is a well-known result. We note from (14.18) that the radiation is polarized in the plane containing $\dot{\mathbf{v}}$ and \mathbf{n} . The total instantaneous power radiated is obtained by integrating (14.21) over all solid angle. Thus

$$P = \frac{2}{3} \frac{e^2}{c^3} |\dot{\mathbf{v}}|^2 \quad (14.22)$$

This is the familiar Larmor result for a nonrelativistic, accelerated charge.

Larmor's formula (14.22) can be generalized by arguments about covariance under Lorentz transformations to yield a result which is valid for arbitrary velocities of the charge. Radiated electromagnetic energy behaves under Lorentz transformation like the fourth component of a 4-vector (see Problem

* In writing angular distributions of radiation we will always exhibit the polarization explicitly by writing the absolute square of a vector which is proportional to the electric field. If the angular distribution for some particular polarization is desired, it can then be obtained by taking the scalar product of the vector with the appropriate polarization vector before squaring.

12.15) This can be used (see *Rohrlich*, p. 109ff) to show that the power P is a Lorentz invariant. If we can find a Lorentz invariant which reduces to the Larmor formula (14.22) for $\beta \ll 1$, then we have the desired generalization. There are, of course, many Lorentz invariants which reduce to the desired form when $\beta \rightarrow 0$. But from (14.14) it is evident that the general result must involve only β and $\dot{\beta}$. With this restriction on the order of derivatives which can appear the result is unique. To find the appropriate generalization we write Larmor's formula in the suggestive form:

$$P = \frac{2}{3} \frac{e^2}{m^2 c^3} \left(\frac{d\mathbf{p}}{dt} \cdot \frac{d\mathbf{p}}{dt} \right) \quad (14.23)$$

where m is the mass of the charged particle, and \mathbf{p} its momentum. The Lorentz invariant generalization is

$$P = -\frac{2}{3} \frac{e^2}{m^2 c^3} \left(\frac{dp_\mu}{d\tau} \frac{dp^\mu}{d\tau} \right) \quad (14.24)$$

where $d\tau = dt/\gamma$ is the proper time element, and p^μ is the charged particle's momentum-energy 4-vector.* To check that (14.24) reduces properly to (14.23) as $\beta \rightarrow 0$ we evaluate the 4-vector scalar product,

$$-\frac{dp_\mu}{d\tau} \frac{dp^\mu}{d\tau} = \left(\frac{d\mathbf{p}}{d\tau} \right)^2 - \frac{1}{c^2} \left(\frac{dE}{d\tau} \right)^2 = \left(\frac{d\mathbf{p}}{d\tau} \right)^2 - \beta^2 \left(\frac{d\mathbf{p}}{d\tau} \right)^2 \quad (14.25)$$

If (14.24) is expressed in terms of the velocity and acceleration by means of $E = \gamma mc^2$ and $\mathbf{p} = \gamma m\mathbf{v}$, we obtain the Liénard result (1898):

$$P = \frac{2}{3} \frac{e^2}{c} \gamma^6 [(\dot{\beta})^2 - (\boldsymbol{\beta} \times \dot{\boldsymbol{\beta}})^2] \quad (14.26)$$

One area of application of the relativistic expression for radiated power is that of charged-particle accelerators. Radiation losses are sometimes the limiting factor in the maximum practical energy attainable. For a given applied force (i.e., a given rate of change of momentum) the radiated power (14.24) depends inversely on the square of the mass of the particle involved. Consequently these radiative effects are largest for electrons.

In a linear accelerator the motion is one dimensional. From (14.25) it is evident that in that case the radiated power is

$$P = \frac{2}{3} \frac{e^2}{m^2 c^3} \left(\frac{dp}{dt} \right)^2 \quad (14.27)$$

* That (14.24) is unique can be seen by noting that a Lorentz invariant is formed by taking scalar products of 4-vectors or higher-rank tensors. The available 4-vectors are p^μ and $dp^\mu/d\tau$. Only form (14.24) reduces to the Larmor formula for $\beta \rightarrow 0$. Contraction of higher-rank tensors such as $p^\mu (dp^\nu/d\tau)$ can be shown to vanish, or to give results proportional to (14.24) or m^2 .

The rate of change of momentum is equal to the change in energy of the particle per unit distance. Consequently

$$P = \frac{2}{3} \frac{e^2}{m^2 c^3} \left(\frac{dE}{dx} \right)^2 \quad (14.28)$$

showing that for linear motion the power radiated depends only on the external forces which determine the rate of change of particle energy with distance, not on the actual energy or momentum of the particle. The ratio of power radiated to power supplied by the external sources is

$$\frac{P}{(dE/dt)} = \frac{2}{3} \frac{e^2}{m^2 c^3} \frac{1}{v} \frac{dE}{dx} \rightarrow \frac{2}{3} \frac{(e^2/mc^2)}{mc^2} \frac{dE}{dx} \quad (14.29)$$

where the last form holds for relativistic particles ($\beta \rightarrow 1$). Equation (14.29) shows that the radiation loss in an electron linear accelerator will be unimportant unless the gain in energy is of the order of $mc^2 = 0.511$ MeV in a distance of $e^2/mc^2 = 2.82 \times 10^{-13}$ cm, or of the order of 2×10^{14} MeV/meter! Typical energy gains are less than 10 MeV/meter. Radiation losses are completely negligible in linear accelerators, whether for electrons or heavier particles.

Circumstances change drastically in circular accelerators like the synchrotron or betatron. In such machines the momentum \mathbf{p} changes rapidly in direction as the particle rotates, but the change in energy per revolution is small. This means that

$$\left| \frac{d\mathbf{p}}{d\tau} \right| = \gamma \omega |\mathbf{p}| \gg \frac{1}{c} \frac{dE}{d\tau} \quad (14.30)$$

Then the radiated power (14.24) can be written approximately

$$P = \frac{2}{3} \frac{e^2}{m^2 c^3} \gamma^2 \omega^2 |\mathbf{p}|^2 = \frac{2}{3} \frac{e^2 c}{\rho^2} \beta^4 \gamma^4 \quad (14.31)$$

where we have used $\omega = (c\beta/\rho)$, ρ being the orbit radius. This result was first obtained by Liénard in 1898. The radiative-energy loss per revolution is

$$\delta E = \frac{2\pi\rho}{c\beta} P = \frac{4\pi}{3} \frac{e^2}{\rho} \beta^3 \gamma^4 \quad (14.32)$$

For high-energy electrons ($\beta \approx 1$) this has the numerical value,

$$\delta E(\text{MeV}) = 8.85 \times 10^{-2} \frac{[E(\text{GeV})]^4}{\rho(\text{meters})} \quad (14.33)$$

In the first electron synchrotrons, $\rho \approx 1$ meter, $E_{\max} \approx 0.3$ GeV. Hence $\delta E_{\max} \approx 1$ keV per revolution. This was less than, but not negligible compared to, the energy gain of a few kilovolts per turn. At higher energies the limitation on available radiofrequency power to overcome the radiation loss becomes a dominant consideration. In the 10 GeV Cornell electron synchrotron, for

example, the orbit radius is $\rho \sim 100$ meters, the maximum magnetic field is ~ 3.3 kG, and the r - f voltage per turn is 10.5 MV at 10 GeV. According to (14.33) the loss per turn is 8.85 MeV. These same general considerations apply to electron-positron storage rings, where r - f power must be supplied just to maintain the beams at a constant energy as they circulate.

The power radiated in circular electron accelerators can be expressed numerically as

$$P \text{ (watts)} = 10^6 \delta E \text{ (MeV)} J \text{ (amp)} \quad (14.34)$$

where J is the circulating beam current. This equation is valid if the emission of radiation from the different electrons in the circulating beam is incoherent. In the largest electron synchrotrons the radiated power amounts to ≥ 1 watt per microampere of beam. Although this power dissipation is very small the radiated energy is readily detected and has some interesting properties which will be discussed in Section 14.6.

14.3 Angular Distribution of Radiation Emitted by an Accelerated Charge

For an accelerated charge in nonrelativistic motion the angular distribution shows a simple $\sin^2 \Theta$ behavior, as given by (14.21), where Θ is measured relative to the direction of acceleration. For relativistic motion the acceleration fields depend on the velocity as well as the acceleration. Consequently the angular distribution is more complicated. From (14.14) the radial component of Poynting's vector can be calculated to be

$$[\mathbf{S} \cdot \mathbf{n}]_{\text{ret}} = \frac{e^2}{4\pi c} \left\{ \frac{1}{R^2} \left| \frac{\mathbf{n} \times [(\mathbf{n} - \boldsymbol{\beta}) \times \dot{\boldsymbol{\beta}}]}{(1 - \boldsymbol{\beta} \cdot \mathbf{n})^3} \right|^2 \right\} \quad (14.35)$$

It is evident that there are two types of relativistic effect present. One is the effect of the specific spatial relationship between $\boldsymbol{\beta}$ and $\dot{\boldsymbol{\beta}}$, which will determine the detailed angular distribution. The other is a general, relativistic effect arising from the transformation from the rest frame of the particle to the observer's frame and manifesting itself by the presence of the factors $(1 - \boldsymbol{\beta} \cdot \mathbf{n})$ in the denominator of (14.35). For ultrarelativistic particles the latter effect dominates the whole angular distribution.

In (14.35) $\mathbf{S} \cdot \mathbf{n}$ is the energy per unit area per unit time detected at an observation point at time t of radiation emitted by the charge at time $t' = t - R(t')/c$. If we wanted to calculate the energy radiated during a finite period of acceleration, say from $t' = T_1$ to $t' = T_2$, we would write

$$E = \int_{t=T_1+[R(T_1)/c]}^{t=T_2+[R(T_2)/c]} [\mathbf{S} \cdot \mathbf{n}]_{\text{ret}} dt = \int_{t'=T_1}^{t'=T_2} (\mathbf{S} \cdot \mathbf{n}) \frac{dt}{dt'} dt' \quad (14.36)$$

Thus we see that the useful and meaningful quantity is $(\mathbf{S} \cdot \mathbf{n}) (dt/dt')$, the power radiated per unit area in terms of the charge's own time. We therefore define the power radiated per unit solid angle to be

$$\frac{dP(t')}{d\Omega} = R^2 (\mathbf{S} \cdot \mathbf{n}) \frac{dt}{dt'} = R^2 \mathbf{S} \cdot \mathbf{n} (1 - \boldsymbol{\beta} \cdot \mathbf{n}) \quad (14.37)$$

If we imagine the charge to be accelerated only for a short time during which $\boldsymbol{\beta}$ and $\dot{\boldsymbol{\beta}}$ are essentially constant in direction and magnitude, and we observe the radiation far enough away from the charge that \mathbf{n} and R change negligibly during the acceleration interval, then (14.37) is proportional to the angular distribution of the energy radiated. With (14.35) for the Poynting's vector, the angular distribution is

$$\frac{dP(t')}{d\Omega} = \frac{e^2}{4\pi c} \frac{|\mathbf{n} \times \{(\mathbf{n} - \boldsymbol{\beta}) \times \dot{\boldsymbol{\beta}}\}|^2}{(1 - \mathbf{n} \cdot \boldsymbol{\beta})^5} \quad (14.38)$$

The simplest example of (14.38) is linear motion in which $\boldsymbol{\beta}$ and $\dot{\boldsymbol{\beta}}$ are parallel. If θ is the angle of observation measured from the common direction of $\boldsymbol{\beta}$ and $\dot{\boldsymbol{\beta}}$, then (14.38) reduces to

$$\frac{dP(t')}{d\Omega} = \frac{e^2 \dot{v}^2}{4\pi c^3} \frac{\sin^2 \theta}{(1 - \beta \cos \theta)^5} \quad (14.39)$$

For $\beta \ll 1$, this is the Larmor result (14.21). But as $\beta \rightarrow 1$, the angular distribution is tipped forward more and more and increases in magnitude, as indicated schematically in Fig. 14.4. The angle θ_{\max} for which the intensity is a maximum is

$$\theta_{\max} = \cos^{-1} \left[\frac{1}{3\beta} (\sqrt{1 + 15\beta^2} - 1) \right] \rightarrow \frac{1}{2\gamma} \quad (14.40)$$

where the last form is the limiting value for $\beta \rightarrow 1$. In this same limit the peak intensity is proportional to γ^8 . Even for $\beta = 0.5$, corresponding to electrons of ~ 80 keV kinetic energy, $\theta_{\max} = 38.2^\circ$. For relativistic particles, θ_{\max} is very small, being of the order of the ratio of the rest energy of the particle to its total energy. Thus the angular distribution is confined to a very narrow cone in the direction

Fig. 14.4 Radiation pattern for charge accelerated in its direction of motion. The two patterns are not to scale, the relativistic one (appropriate for $\gamma \sim 2$) having been reduced by a factor $\sim 10^2$ for the same acceleration.

Fig. 14.5 Angular distribution of radiation for relativistic particle.

of motion. For such small angles the angular distribution (14.39) can be written approximately

$$\frac{dP(t')}{d\Omega} \approx \frac{8}{\pi} \frac{e^2 \dot{v}^2}{c^3} \gamma^8 \frac{(\gamma\theta)^2}{(1 + \gamma^2 \theta^2)^5} \quad (14.41)$$

The natural angular unit is evidently γ^{-1} . The angular distribution is shown in Fig. 14.5 with angles measured in these units. The peak occurs at $\gamma\theta = \frac{1}{2}$, and the half-power points at $\gamma\theta = 0.23$ and $\gamma\theta = 0.91$. The root mean square angle of emission of radiation in the relativistic limit is

$$\langle \theta^2 \rangle^{1/2} = \frac{1}{\gamma} = \frac{mc^2}{E} \quad (14.42)$$

This is typical of the relativistic radiation patterns, regardless of the vectorial relation between $\boldsymbol{\beta}$ and $\dot{\boldsymbol{\beta}}$. The total power radiated can be obtained by integrating (14.39) over all angles. Thus

$$P(t') = \frac{2}{3} \frac{e^2}{c^3} \dot{v}^2 \gamma^6 \quad (14.43)$$

in agreement with (14.26) and (14.27).

Another example of angular distribution of radiation is that for a charge in instantaneously circular motion with its acceleration $\dot{\boldsymbol{\beta}}$ perpendicular to its velocity $\boldsymbol{\beta}$. We choose a coordinate system such that instantaneously $\boldsymbol{\beta}$ is in the z direction and $\dot{\boldsymbol{\beta}}$ is in the x direction. With the customary polar angles θ, ϕ defining the direction of observation, as shown in Fig. 14.6, the general formula (14.38) reduces to

$$\frac{dP(t')}{d\Omega} = \frac{e^2}{4\pi c^3} \frac{|\dot{\mathbf{v}}|^2}{(1 - \beta \cos \theta)^3} \left[1 - \frac{\sin^2 \theta \cos^2 \phi}{\gamma^2 (1 - \beta \cos \theta)^2} \right] \quad (14.44)$$

We note that, although the detailed angular distribution is different from the linear acceleration case, the same characteristic relativistic peaking at forward angles is present. In the relativistic limit ($\gamma \gg 1$), the angular distribution can be

Fig. 14.6

written approximately

$$\frac{dP(t')}{d\Omega} \approx \frac{2}{\pi} \frac{e^2}{c^3} \gamma^6 \frac{|\dot{\mathbf{v}}|^2}{(1 + \gamma^2 \theta^2)^3} \left[1 - \frac{4\gamma^2 \theta^2 \cos^2 \phi}{(1 + \gamma^2 \theta^2)^2} \right] \quad (14.45)$$

The root mean square angle of emission in this approximation is given by (14.42), just as for one-dimensional motion. The total power radiated can be found by integrating (14.44) over all angles or from (14.26):

$$P(t') = \frac{2}{3} \frac{e^2}{c^3} \frac{|\dot{\mathbf{v}}|^2}{\gamma^4} \quad (14.46)$$

It is instructive to compare the power radiated for acceleration parallel to the velocity (14.43) or (14.27) with the power radiated for acceleration perpendicular to the velocity (14.46) for the same magnitude of applied force. For circular motion, the magnitude of the rate of change of momentum (which is equal to the applied force) is $\gamma m \dot{\mathbf{v}}$. Consequently, (14.46) can be written

$$P_{\text{circular}}(t') = \frac{2}{3} \frac{e^2}{m^2 c^3} \gamma^2 \left(\frac{d\mathbf{p}}{dt} \right)^2 \quad (14.47)$$

When this is compared to the corresponding result (14.27) for rectilinear motion, we find that for a given magnitude of applied force the radiation emitted with a transverse acceleration is a factor of γ^2 larger than with a parallel acceleration.

14.4 Radiation Emitted by a Charge in Arbitrary, Extremely Relativistic Motion

For a charged particle undergoing arbitrary, extremely relativistic motion the radiation emitted at any instant can be thought of as a coherent superposition of contributions coming from the components of acceleration parallel to and

perpendicular to the velocity. But we have just seen that for comparable parallel and perpendicular forces the radiation from the parallel component is negligible (of order $1/\gamma^2$) compared to that from the perpendicular component. Consequently we may neglect the parallel component of acceleration and approximate the radiation intensity by that from the perpendicular component alone. In other words, the radiation emitted by a charged particle in arbitrary, extreme relativistic motion is approximately the same as that emitted by a particle moving instantaneously along the arc of a circular path whose radius of curvature ρ is given by

$$\rho = \frac{v^2}{\dot{v}_\perp} \approx \frac{c^2}{\dot{v}_\perp} \quad (14.48)$$

where \dot{v}_\perp is the perpendicular component of acceleration. The form of the angular distribution of radiation is (14.44) or (14.45). It corresponds to a narrow cone or searchlight beam of radiation directed along the instantaneous velocity vector of the charge.

For an observer with a frequency-sensitive detector the confinement of the radiation to a narrow pencil parallel to the velocity has important consequences. The radiation will be visible only when the particle's velocity is directed towards the observer. For a particle in arbitrary motion the observer will detect a pulse or burst of radiation of very short time duration (or a succession of such bursts if the particle is in periodic motion), as sketched in Fig. 14.7. Since the angular width of the beam is of the order of γ^{-1} , the particle will travel only a distance of the order of

$$d = \frac{\rho}{\gamma}$$

corresponding to a time,

$$\Delta t = \frac{\rho}{\gamma v}$$

while illuminating the observer. To make the argument conceptually simple neglect the curvature of the path during this time and suppose that a sharp rectangular pulse of radiation is emitted. In the time Δt the front edge of the pulse travels a distance,

$$D = c \Delta t = \frac{\rho}{\gamma \beta}$$

Since the particle is moving in the same direction with speed v and moves a distance d in the time Δt , the rear edge of the pulse will be only a distance

$$L = D - d = \left(\frac{1}{\beta} - 1 \right) \frac{\rho}{\gamma} \approx \frac{\rho}{2\gamma^3} \quad (14.49)$$

behind the front edge as the pulse moves off. The pulse length is thus L in space,

Fig. 14.7 A relativistic particle in periodic motion emits a spiral radiation pattern that an observer at the point A detects as short bursts of radiation of time duration $T = L/c$, occurring at regular intervals $T_0 = L_0/c$. The pulse length is given by (14.49), while the interval $T_0 = 2\pi\rho/v \approx 2\pi\rho/c$. For beautiful diagrams of field lines of radiating particles, see R. Y. Tsien, *Am. J. Phys.* **40**, 46 (1972).

or L/c in time. From general arguments about the Fourier decomposition of finite wave trains this implies that the spectrum of the radiation will contain appreciable frequency components up to a critical frequency,

$$\omega_c \sim \frac{c}{L} \sim \left(\frac{c}{\rho}\right) \gamma^3 \quad (14.50)$$

For circular motion c/ρ is the angular frequency of rotation ω_0 and even for arbitrary motion it plays the role of a fundamental frequency. Equation (14.50) shows that a relativistic particle emits a broad spectrum of frequencies, up to γ^3

times the fundamental frequency. In a 200 MeV synchrotron, $\gamma_{\max} \approx 400$, while $\omega_0 \approx 3 \times 10^8 \text{ sec}^{-1}$. The frequency spectrum of emitted radiation extends up to $\sim 2 \times 10^{16} \text{ sec}^{-1}$, or down to a wavelength of 1000 angstroms, even though the fundamental frequency is in the 100 MHz range. For the 10 GeV machine at Cornell, $\gamma_{\max} \approx 2 \times 10^4$ and $\omega_0 \approx 3 \times 10^6 \text{ sec}^{-1}$. This means that $\omega_c \approx 2.4 \times 10^{19} \text{ sec}^{-1}$, corresponding to 16 keV X-rays. In Section 14.6 we discuss in detail the angular distribution of the different frequency components, as well as the total energy radiated as a function of frequency.

14.5 Distribution in Frequency and Angle of Energy Radiated by Accelerated Charges

The qualitative arguments of the previous section show that for relativistic motion the radiated energy is spread over a wide range of frequencies. The range of the frequency spectrum was estimated by appealing to properties of Fourier integrals. The argument can be made precise and quantitative by the use of Parseval's theorem of Fourier analysis.

The general form of the power radiated per unit solid angle is

$$\frac{dP(t)}{d\Omega} = |\mathbf{A}(t)|^2 \quad (14.51)$$

where

$$\mathbf{A}(t) = \left(\frac{c}{4\pi} \right)^{1/2} [\mathbf{RE}]_{\text{ret}} \quad (14.52)$$

\mathbf{E} being the electric field (14.14). In (14.51) the instantaneous power is expressed in the observer's time (contrary to the definition in Section 14.3), since we wish to consider a frequency spectrum in terms of the observer's frequencies. For definiteness we think of the acceleration occurring for some finite interval of time, or at least falling off for remote past and future times, so that the total energy radiated is finite. Furthermore, the observation point is considered far enough away from the charge that the spatial region spanned by the charge while accelerated subtends a small solid angle element at the observation point.

The total energy radiated per unit solid angle is the time integral of (14.51):

$$\frac{dW}{d\Omega} = \int_{-\infty}^{\infty} |\mathbf{A}(t)|^2 dt \quad (14.53)$$

This can be expressed alternatively as an integral over a frequency spectrum by use of Fourier transforms. We introduce the Fourier transform $\mathbf{A}(\omega)$ of $\mathbf{A}(t)$,

$$\mathbf{A}(\omega) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \mathbf{A}(t) e^{i\omega t} dt \quad (14.54)$$

and its inverse,

$$\mathbf{A}(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \mathbf{A}(\omega) e^{-i\omega t} d\omega \quad (14.55)$$

Then (14.53) can be written

$$\frac{dW}{d\Omega} = \frac{1}{2\pi} \int_{-\infty}^{\infty} dt \int_{-\infty}^{\infty} d\omega' \mathbf{A}^*(\omega') \cdot \mathbf{A}(\omega) e^{i(\omega' - \omega)t} \quad (14.56)$$

Interchanging the orders of time and frequency integration, we see that the time integral is just a Fourier representation of the delta function $\delta(\omega' - \omega)$. Consequently the energy radiated per unit solid angle becomes

$$\frac{dW}{d\Omega} = \int_{-\infty}^{\infty} |\mathbf{A}(\omega)|^2 d\omega \quad (14.57)$$

The equality of (14.57) and (14.53), with suitable mathematical restrictions on the function $\mathbf{A}(t)$, is a special case of Parseval's theorem. It is customary to integrate only over positive frequencies, since the sign of the frequency has no physical meaning. Then the relation,

$$\frac{dW}{d\Omega} = \int_0^{\infty} \frac{d^2 I(\omega, \mathbf{n})}{d\omega d\Omega} d\omega \quad (14.58)$$

defines a quantity which is the energy radiated per unit solid angle per unit frequency interval:

$$\frac{d^2 I}{d\omega d\Omega} = |\mathbf{A}(\omega)|^2 + |\mathbf{A}(-\omega)|^2 \quad (14.59)$$

If $\mathbf{A}(t)$ is real, from (14.55) it is evident that $\mathbf{A}(-\omega) = \mathbf{A}^*(\omega)$. Then

$$\frac{d^2 I}{d\omega d\Omega} = 2 |\mathbf{A}(\omega)|^2 \quad (14.60)$$

This result relates in a quantitative way the behavior of the power radiated as a function of time to the frequency spectrum of the energy radiated.

By using (14.14) for the electric field of an accelerated charge we can obtain a general expression for the energy radiated per unit solid angle per unit frequency interval in terms of an integral over the trajectory of the particle. We must calculate the Fourier transform (14.54) of $\mathbf{A}(t)$ given by (14.52). Using (14.14), we find

$$\mathbf{A}(\omega) = \left(\frac{e^2}{8\pi^2 c} \right)^{1/2} \int_{-\infty}^{\infty} e^{i\omega t} \left[\frac{\mathbf{n} \times [(\mathbf{n} - \boldsymbol{\beta}) \times \dot{\boldsymbol{\beta}}]}{(1 - \boldsymbol{\beta} \cdot \mathbf{n})^3} \right]_{\text{ret}} dt \quad (14.61)$$

where ret means evaluated at $t' + [R(t')/c] = t$. We change the variable of

integration from t to t' , thereby obtaining the result:

$$\mathbf{A}(\omega) = \left(\frac{e^2}{8\pi^2 c} \right)^{1/2} \int_{-\infty}^{\infty} e^{i\omega(t' + [R(t')/c])} \frac{\mathbf{n} \times [(\mathbf{n} - \boldsymbol{\beta}) \times \dot{\boldsymbol{\beta}}]}{(1 - \boldsymbol{\beta} \cdot \mathbf{n})^2} dt' \quad (14.62)$$

Since the observation point is assumed to be far away from the region of space where the acceleration occurs, the unit vector \mathbf{n} is sensibly constant in time. Furthermore the distance $R(t')$ can be approximated as

$$R(t') \approx x - \mathbf{n} \cdot \mathbf{r}(t') \quad (14.63)$$

where x is the distance from an origin O to the observation point P , and $\mathbf{r}(t')$ is the position of the particle relative to O , as shown in Fig. 14.8. Then, apart from an overall phase factor, (14.62) becomes

$$\mathbf{A}(\omega) = \left(\frac{e^2}{8\pi^2 c} \right)^{1/2} \int_{-\infty}^{\infty} e^{i\omega(t - \mathbf{n} \cdot \mathbf{r}(t)/c)} \frac{\mathbf{n} \times [(\mathbf{n} - \boldsymbol{\beta}) \times \dot{\boldsymbol{\beta}}]}{(1 - \boldsymbol{\beta} \cdot \mathbf{n})^2} dt \quad (14.64)$$

The primes on the time variable have been omitted for brevity. The energy radiated per unit solid angle per unit frequency interval (14.60) is accordingly

$$\frac{d^2 I}{d\omega d\Omega} = \frac{e^2}{4\pi^2 c} \left| \int_{-\infty}^{\infty} \frac{\mathbf{n} \times [(\mathbf{n} - \boldsymbol{\beta}) \times \dot{\boldsymbol{\beta}}]}{(1 - \boldsymbol{\beta} \cdot \mathbf{n})^2} e^{i\omega(t - \mathbf{n} \cdot \mathbf{r}(t)/c)} dt \right|^2 \quad (14.65)$$

For a specified motion $\mathbf{r}(t)$ is known, $\boldsymbol{\beta}(t)$ and $\dot{\boldsymbol{\beta}}(t)$ can be computed, and the integral can be evaluated as a function of ω and the direction of \mathbf{n} . If accelerated motion of more than one charge is involved, a coherent sum of amplitudes $\mathbf{A}_j(\omega)$, one for each charge, must replace the single amplitude in (14.65) (see Problems 14.12, 15.3–15.6).

Even though (14.65) has the virtue that the time interval of integration is explicitly shown to be confined to times for which the acceleration is different from zero, a simpler expression for some purposes can be obtained by an integration by parts in (14.64). It is easy to demonstrate that the integrand in (14.64), excluding the exponential, is a perfect differential:

$$\frac{\mathbf{n} \times [(\mathbf{n} - \boldsymbol{\beta}) \times \dot{\boldsymbol{\beta}}]}{(1 - \boldsymbol{\beta} \cdot \mathbf{n})^2} = \frac{d}{dt} \left[\frac{\mathbf{n} \times (\mathbf{n} \times \boldsymbol{\beta})}{1 - \boldsymbol{\beta} \cdot \mathbf{n}} \right] \quad (14.66)$$

Fig. 14.8

Then an integration by parts leads to the intensity distribution:

$$\frac{d^2 I}{d\omega d\Omega} = \frac{e^2 \omega^2}{4\pi^2 c} \left| \int_{-\infty}^{\infty} \mathbf{n} \times (\mathbf{n} \times \boldsymbol{\beta}) e^{i\omega(t - \mathbf{n} \cdot \mathbf{r}(t)/c)} dt \right|^2 \quad (14.67)$$

The reader may rightly ask whether (14.67) is correct in all circumstances as it stands. Suppose that the acceleration is different from zero only for $T_1 \leq t \leq T_2$. Why then is the integration in (14.67) over all time? The precise answer is that (14.67) can be shown, by adding and subtracting the integrals over the times when the velocity is constant, to follow from (14.65) provided ambiguities at $t = \pm\infty$ are resolved by inserting a convergence factor $e^{-\epsilon|t|}$ in the integrand and taking the limit $\epsilon \rightarrow 0$ after evaluating the integral. In processes like beta decay where the classical description involves the almost instantaneous halting or setting in motion of charges, extra care must be taken to specify each particle's velocity as a physically sensible function of time.

It should be observed that in (14.67) and (14.65) the polarization of the emitted radiation is specified by the direction of the vector integral in each. The intensity of radiation of a certain fixed polarization can be obtained by taking the scalar product of the appropriate unit polarization vector with the vector integral before forming the absolute square.

For a number of charges e_j in accelerated motion the integrand in (14.67) involves the replacement,

$$e\boldsymbol{\beta} e^{-i(\omega/c)\mathbf{n} \cdot \mathbf{r}(t)} \rightarrow \sum_{j=1}^N e_j \boldsymbol{\beta}_j e^{-i(\omega/c)\mathbf{n} \cdot \mathbf{r}_j(t)} \quad (14.68)$$

In the limit of a continuous distribution of charge in motion the sum over j becomes an integral over the current density $\mathbf{J}(\mathbf{x}, t)$:

$$e\boldsymbol{\beta} e^{-i(\omega/c)\mathbf{n} \cdot \mathbf{r}(t)} \rightarrow \frac{1}{c} \int d^3x \mathbf{J}(\mathbf{x}, t) e^{-i(\omega/c)\mathbf{n} \cdot \mathbf{x}} \quad (14.69)$$

Then the intensity distribution becomes

$$\frac{d^2 I}{d\omega d\Omega} = \frac{\omega^2}{4\pi^2 c^3} \left| \int dt \int d^3x \mathbf{n} \times [\mathbf{n} \times \mathbf{J}(\mathbf{x}, t)] e^{i\omega[t - (\mathbf{n} \cdot \mathbf{x})/c]} \right|^2 \quad (14.70)$$

a result which can be obtained from the direct solution of the inhomogeneous wave equation for the vector potential.

Of some interest is the radiation from a moving magnetic moment. We recall from Chapter 5 that a magnetization density $\mathcal{M}(\mathbf{x}, t)$ is equivalent to a current $\mathbf{J}_M = c \nabla \times \mathcal{M}$. This current can be substituted into (14.70), but there is another contribution. In Chapter 11 we found that a moving magnetization has an associated electric polarization. From the Ampère-Maxwell equation it is evident that the effective source current for a *moving* magnetic moment is therefore

$$\mathbf{J}_{\text{eff}} = c \nabla \times \mathcal{M} + \frac{\partial \mathcal{P}}{\partial t} \quad (14.71)$$

where \mathcal{P} is the associated electric polarization density. Substitution into (14.70) and integrations by parts yield

$$\frac{d^2 I'}{d\omega d\Omega} = \frac{\omega^4}{4\pi^2 c^3} \left| \int dt \int d^3x \mathbf{n} \times [\mathcal{M} + \mathbf{n} \times \mathcal{P}] e^{i\omega(t - \mathbf{n} \cdot \mathbf{x}/c)} \right|^2 \quad (14.72)$$

For a point magnetic moment $\boldsymbol{\mu}(t)$ at the point $\mathbf{r}(t)$, the magnetization is

$$\mathcal{M}(\mathbf{x}, t) = \boldsymbol{\mu}(t) \delta[\mathbf{x} - \mathbf{r}(t)] \quad (14.73a)$$

From (11.149) and the correspondences $\mathbf{B} \rightarrow -\mathcal{M}$, $\mathbf{E} \rightarrow \mathcal{P}$, we infer that a particle with only a magnetic moment in its rest frame K' will appear in frame K where its velocity is $c\boldsymbol{\beta}$ as possessing a magnetic moment and an electric dipole moment,

$$\mathbf{p} = \boldsymbol{\beta} \times \boldsymbol{\mu} \quad (14.73b)$$

where $\boldsymbol{\mu}$ is the magnetic moment as observed in K . The electric polarization density in (14.72) is thus given by

$$\mathcal{P}(\mathbf{x}, t) = \boldsymbol{\beta}(t) \times \boldsymbol{\mu}(t) \delta[\mathbf{x} - \mathbf{r}(t)] \quad (14.73c)$$

With (14.73a) and (14.73c) substituted, (14.72) gives the energy radiated per unit solid angle per unit frequency interval by a moving magnetic moment as

$$\frac{d^2 I'}{d\omega d\Omega} = \frac{\omega^4}{4\pi^2 c^3} \left| \int dt \mathbf{n} \times [\boldsymbol{\mu} + \mathbf{n} \times (\boldsymbol{\beta} \times \boldsymbol{\mu})] e^{i\omega(t - \mathbf{n} \cdot \mathbf{r}(t)/c)} \right|^2 \quad (14.74)$$

We note that there is a characteristic difference of a factor ω^2 between the radiated intensity from a magnetic dipole and an accelerated charge, apart from the frequency dependence of the integrals.

The general formulas developed in this section, especially (14.65) and (14.67), will be applied in this chapter and subsequent ones to various problems involving the emission of radiation. The magnetic-moment formula (14.74) will be applied to the problem of radiation emitted in orbital-electron capture by nuclei in Chapter 15.

14.6 Frequency Spectrum of Radiation Emitted by a Relativistic Charged Particle in Instantaneously Circular Motion

In Section 14.4 we saw that the radiation emitted by an extremely relativistic particle subject to arbitrary accelerations is equivalent to that emitted by a particle moving instantaneously at constant speed on an appropriate circular path. The radiation is beamed in a narrow cone in the direction of the velocity vector, and is seen by the observer as a short pulse of radiation as the searchlight beam sweeps across the observation point.

To find the distribution of energy in frequency and angle it is necessary to calculate the integral in (14.67). Because the duration of the pulse is very short, it is necessary to know the velocity β and position $\mathbf{r}(t)$ over only a small arc of the trajectory whose tangent points in the general direction of the observation point. Figure 14.9 shows an appropriate coordinate system. The segment of trajectory lies in the x - y plane with instantaneous radius of curvature ρ . Since an integral will be taken over the path, the unit vector \mathbf{n} can be chosen without loss of generality to lie in the x - z plane, making an angle θ (the latitude) with the x axis. Only for very small θ will there be appreciable radiation intensity. The origin of time is chosen so that at $t=0$ the particle is at the origin of coordinates.

The vector part of the integrand in (14.67) can be written

$$\mathbf{n} \times (\mathbf{n} \times \boldsymbol{\beta}) = \beta \left[-\boldsymbol{\epsilon}_{\parallel} \sin \left(\frac{vt}{\rho} \right) + \boldsymbol{\epsilon}_{\perp} \cos \left(\frac{vt}{\rho} \right) \sin \theta \right] \quad (14.75)$$

where $\boldsymbol{\epsilon}_{\parallel} = \boldsymbol{\epsilon}_2$ is a unit vector in the y direction, corresponding to polarization in the plane of the orbit; $\boldsymbol{\epsilon}_{\perp} = \mathbf{n} \times \boldsymbol{\epsilon}_2$ is the orthogonal polarization vector corresponding approximately to polarization perpendicular to the orbit plane (for θ small). The argument of the exponential is

$$\omega \left(t - \frac{\mathbf{n} \cdot \mathbf{r}(t)}{c} \right) = \omega \left[t - \frac{\rho}{c} \sin \left(\frac{vt}{\rho} \right) \cos \theta \right] \quad (14.76)$$

Since we are concerned with small angles θ and comparatively short times around $t=0$, we can expand both trigonometric functions in (14.76) to obtain

$$\omega \left(t - \frac{\mathbf{n} \cdot \mathbf{r}(t)}{c} \right) \approx \frac{\omega}{2} \left[\left(\frac{1}{\gamma^2} + \theta^2 \right) t + \frac{c^2}{3\rho^2} t^3 \right] \quad (14.77)$$

where β has been put equal to unity wherever possible. Using the time estimate $\rho/c\gamma$ for t and the estimate $\langle \theta^2 \rangle^{1/2}$ (14.42) for θ , it is easy to see that neglected terms in (14.77) are of the order of γ^{-2} times those kept.

Fig. 14.9

With the same type of approximations in (14.75) as led to (14.77), the radiated energy distribution (14.67) can be written

$$\frac{d^2 I}{d\omega d\Omega} = \frac{e^2 \omega^2}{4\pi^2 c} \left| -\epsilon_{\parallel} A_{\parallel}(\omega) + \epsilon_{\perp} A_{\perp}(\omega) \right|^2 \quad (14.78)$$

where the amplitudes are*

$$\left. \begin{aligned} A_{\parallel}(\omega) &\simeq \frac{c}{\rho} \int_{-\infty}^{\infty} t \exp \left\{ i \frac{\omega}{2} \left[\left(\frac{1}{\gamma^2} + \theta^2 \right) t + \frac{c^2 t^3}{3\rho^2} \right] \right\} dt \\ A_{\perp}(\omega) &\simeq \theta \int_{-\infty}^{\infty} \exp \left\{ i \frac{\omega}{2} \left[\left(\frac{1}{\gamma^2} + \theta^2 \right) t + \frac{c^2 t^3}{3\rho^2} \right] \right\} dt \end{aligned} \right\} \quad (14.79)$$

A change of variable to $x = \left[ct/\rho \left(\frac{1}{\gamma^2} + \theta^2 \right)^{1/2} \right]$ and introduction of the parameter ξ ,

$$\xi = \frac{\omega \rho}{3c} \left(\frac{1}{\gamma^2} + \theta^2 \right)^{3/2} \quad (14.80)$$

allows us to transform the integrals in $A_{\parallel}(\omega)$ and $A_{\perp}(\omega)$ into the form:

$$\left. \begin{aligned} A_{\parallel}(\omega) &= \frac{\rho}{c} \left(\frac{1}{\gamma^2} + \theta^2 \right) \int_{-\infty}^{\infty} x \exp \left[i \frac{2}{3} \xi \left(x + \frac{1}{3} x^3 \right) \right] dx \\ A_{\perp}(\omega) &= \frac{\rho}{c} \theta \left(\frac{1}{\gamma^2} + \theta^2 \right)^{1/2} \int_{-\infty}^{\infty} \exp \left[i \frac{2}{3} \xi \left(x + \frac{1}{3} x^3 \right) \right] dx \end{aligned} \right\} \quad (14.81)$$

The integrals in (14.81) are identifiable as Airy integrals, or alternatively as modified Bessel functions:

$$\left. \begin{aligned} \int_0^{\infty} x \sin \left[\frac{2}{3} \xi \left(x + \frac{1}{3} x^3 \right) \right] dx &= \frac{1}{\sqrt{3}} K_{2/3}(\xi) \\ \int_0^{\infty} \cos \left[\frac{2}{3} \xi \left(x + \frac{1}{3} x^3 \right) \right] dx &= \frac{1}{\sqrt{3}} K_{1/3}(\xi) \end{aligned} \right\} \quad (14.82)$$

Consequently the energy radiated per unit frequency interval per unit solid angle is

$$\frac{d^2 I}{d\omega d\Omega} = \frac{e^2}{3\pi^2 c} \left(\frac{\omega \rho}{c} \right)^2 \left(\frac{1}{\gamma^2} + \theta^2 \right)^2 \left[K_{2/3}^2(\xi) + \frac{\theta^2}{(1/\gamma^2) + \theta^2} K_{1/3}^2(\xi) \right] \quad (14.83)$$

*The fact that the limits of integration in (14.79) are $t = \pm\infty$ may seem to contradict the approximations made in going from (14.76) to (14.77). The point is that for most frequencies the phase of the integrands in (14.79) oscillates very rapidly and makes the integrands effectively zero for times much smaller than those necessary to maintain the validity of (14.77). Hence the upper and lower limits on the integrals can be taken as infinite without error. Only for frequencies of the order of $\omega \sim (c/\rho) \sim \omega_0$ does the approximation fail. But we have seen in Section 14.4 that for relativistic particles essentially all the frequency spectrum is at much higher frequencies.

The first term in the square bracket corresponds to radiation polarized in the plane of the orbit, and the second to radiation polarized perpendicular to that plane.

We now proceed to examine this somewhat complex result. First we integrate over all frequencies and find that the distribution of energy in angle is

$$\frac{dI}{d\Omega} = \int_0^\infty \frac{d^2I}{d\omega d\Omega} d\omega = \frac{7}{16} \frac{e^2}{\rho} \frac{1}{\left(\frac{1}{\gamma^2} + \theta^2\right)^{5/2}} \left[1 + \frac{5}{7} \frac{\theta^2}{(1/\gamma^2) + \theta^2} \right] \quad (14.84)$$

This shows the characteristic behavior seen in Section 14.3. Equation (14.84) can be obtained directly, of course, by integrating a slight generalization of the circular-motion power formula (14.44) over all times. As in (14.83), the first term in (14.84) corresponds to polarization parallel to the orbital plane, and the second to perpendicular polarization. Integrating over all angles, we find that seven times as much energy is radiated with parallel polarization as with perpendicular polarization. The radiation from a relativistically moving charge is very strongly, but not completely, polarized in the plane of motion.

The properties of the modified Bessel functions summarized in (3.103) and (3.104) show that the intensity of radiation is negligible for $\xi \gg 1$. From (14.80) we see that this will occur at large angles; the greater the frequency, the smaller the critical angle beyond which there will be negligible radiation. This shows that the radiation is largely confined to the plane containing the motion, as shown by (14.84), being more so confined the higher the frequency relative to c/ρ . If ω gets too large, however, we see that ξ will be large at *all* angles. Then there will be negligible total energy emitted at that frequency. The critical frequency ω_c beyond which there is negligible radiation at any angle can be defined by $\xi = 1$ for $\theta = 0$. Then we find

$$\omega_c = 3\gamma^3 \left(\frac{c}{\rho} \right) = 3 \left(\frac{E}{mc^2} \right)^3 \frac{c}{\rho} \quad (14.85)$$

This critical frequency is seen to agree with our qualitative estimate (14.50) of Section 14.4. If the motion of the charge is truly circular, then c/ρ is the fundamental frequency of rotation, ω_0 . Then we can define a critical harmonic frequency $\omega_c = n_c \omega_0$, with harmonic number,

$$n_c = 3 \left(\frac{E}{mc^2} \right)^3 \quad (14.86)$$

Since the radiation is predominantly in the orbital plane for $\gamma \gg 1$, it is instructive to evaluate the angular distribution (14.83) at $\theta = 0$. For frequencies well below the critical frequency ($\omega \ll \omega_c$), we find

$$\left. \frac{d^2I}{d\omega d\Omega} \right|_{\theta=0} \approx \frac{e^2}{c} \left[\frac{\Gamma(\frac{2}{3})}{\pi} \right]^2 \left(\frac{3}{4} \right)^{1/3} \left(\frac{\omega\rho}{c} \right)^{2/3} \quad (14.87)$$

For the opposite limit of $\omega \gg \omega_c$, the result is

$$\left. \frac{d^2 I}{d\omega d\Omega} \right|_{\theta=0} \approx \frac{3}{2\pi} \frac{e^2}{c} \gamma^2 \frac{\omega}{\omega_c} e^{-2\omega/\omega_c} \quad (14.88)$$

These limiting forms show that the spectrum at $\theta=0$ increases with frequency roughly as $\omega^{2/3}$ well below the critical frequency, reaches a maximum in the neighborhood of ω_c , and then drops exponentially to zero above that frequency.

The spread in angle at a fixed frequency can be estimated by determining the angle θ_c at which $\xi(\theta_c) \approx \xi(0) + 1$. In the low-frequency range ($\omega \ll \omega_c$), $\xi(0)$ is very small, so that $\xi(\theta_c) \approx 1$. This gives

$$\theta_c \approx \left(\frac{3c}{\omega \rho} \right)^{1/3} = \frac{1}{\gamma} \left(\frac{\omega_c}{\omega} \right)^{1/3} \quad (14.89)$$

We note that the low-frequency components are emitted at much wider angles than the average, $\langle \theta^2 \rangle^{1/2} \sim \gamma^{-1}$. In the high-frequency limit ($\omega > \omega_c$), $\xi(0)$ is large compared to unity. Then the intensity falls off in angle approximately as

$$\left. \frac{d^2 I}{d\omega d\Omega} \right|_{\theta=0} \approx \left. \frac{d^2 I}{d\omega d\Omega} \right|_{\theta=0} \cdot e^{-3\omega\gamma^2\theta^2/\omega_c} \quad (14.90)$$

Thus the critical angle, defined by the $1/e$ point, is

$$\theta_c \approx \frac{1}{\gamma} \left(\frac{\omega_c}{3\omega} \right)^{1/2} \quad (14.91)$$

This shows that the high-frequency components are confined to an angular range much smaller than average. Figure 14.10 shows qualitatively the angular distribution for frequencies small compared with, of the order of, and much larger than ω_c . The natural unit of angle $\gamma\theta$ is used.

The frequency distribution of the total energy emitted as the particle passes by can be found by integrating (14.83) over angles:

$$\frac{dI}{d\omega} = 2\pi \int_{-\pi/2}^{\pi/2} \left. \frac{d^2 I}{d\omega d\Omega} \right|_{\theta=0} \cos \theta d\theta \approx 2\pi \int_{-\infty}^{\infty} \left. \frac{d^2 I}{d\omega d\Omega} \right|_{\theta=0} d\theta \quad (14.92)$$

(remember that θ is the latitude). We can estimate the integral for the low-frequency range by using the value of the angular distribution (14.87) at $\theta=0$ and the critical angle θ_c (14.89). Then we obtain

$$\frac{dI}{d\omega} \sim 2\pi\theta_c \left. \frac{d^2 I}{d\omega d\Omega} \right|_{\theta=0} \sim \frac{e^2}{c} \left(\frac{\omega \rho}{c} \right)^{1/3} \quad (14.93)$$

showing that the spectrum increases as $\omega^{1/3}$ for $\omega \ll \omega_c$. This gives a very broad, flat spectrum at frequencies below ω_c . For the high-frequency limit where $\omega \gg \omega_c$

Fig. 14.10 Differential frequency spectrum as a function of angle. For frequencies comparable to the critical frequency ω_c , the radiation is confined to angles of the order of γ^{-1} . For much smaller (larger) frequencies, the angular spread is larger (smaller).

we can integrate (14.90) over angles to obtain the reasonably accurate result,

$$\frac{dI}{d\omega} \approx \sqrt{3\pi} \frac{e^2}{c} \gamma \left(\frac{\omega}{\omega_c} \right)^{1/2} e^{-2\omega/\omega_c} \quad (14.94)$$

A proper integration of (14.83) over angles yields the expression,*

$$\frac{dI}{d\omega} = 2\sqrt{3} \frac{e^2}{c} \gamma \frac{\omega}{\omega_c} \int_{2\omega/\omega_c}^{\infty} K_{5/3}(x) dx \quad (14.95)$$

In the limit $\omega \ll \omega_c$ this reduces to the form (14.93) with a numerical coefficient 3.25, while for $\omega \gg \omega_c$ it is equal to (14.94). The behavior of $dI/d\omega$ as a function of frequency is shown in Fig. 14.11. The peak intensity is of the order of $e^2\gamma/c$, and the total energy is of the order of $e^2\gamma\omega_c/c = 3e^2\gamma^4/\rho$. This is in agreement with the value of $4\pi e^2\gamma^4/3\rho$ for the radiative loss per revolution (14.32) in circular accelerators.

The radiation represented by (14.83) and (14.95) is called *synchrotron radiation* because it was first observed in electron synchrotrons (1948). The theoretical results are much older, however, having been obtained for circular motion by *Schott* (1912) although their expression in the present amenable form is due to *Schwinger* (*op. cit.*). For periodic circular motion the spectrum is actually discrete, being composed of frequencies which are integral multiples of

* This result and the differential distribution (14.83) are derived in a somewhat different way by J. Schwinger, *Phys. Rev.* **75**, 1912 (1949). Schwinger later showed that the first order quantum mechanical corrections to the classical results involve the replacement of $\omega \rightarrow \omega(1 + \hbar\omega/E)$ in $\omega^{-1} d^2I/d\omega d\Omega$ or $\omega^{-1} dI/d\omega$ [*Proc. Nat. Acad. Sci.* **40**, 132 (1954)] and are thus negligible provided $\hbar\omega_c \ll E$, or equivalently, $\gamma \ll (\rho mc/\hbar)^{1/2}$.

Fig. 14.11 Synchrotron radiation spectrum (energy radiated per unit frequency interval) as a function of frequency. The intensity is measured in units of $\gamma^2 c$, while the frequency is expressed in units of ω_c (14.85).

the fundamental frequency $\omega_0 = c/\rho$. Since the charged particle repeats its motion at a rate of $c/2\pi\rho$ revolutions per second, it is convenient to talk about the angular distribution of power radiated into the n th multiple of ω_0 instead of the energy radiated per unit frequency interval per passage of the particle. To obtain the harmonic power expressions we merely multiply $dI/d\omega$ (14.95) or $d^2I/d\omega d\Omega$ (14.83) by the repetition rate $c/2\pi\rho$ to convert energy to power, and by $\omega_0 = c/\rho$ to convert per unit frequency interval to per harmonic. Thus

$$\left. \begin{aligned} \frac{dP_n}{d\Omega} &= \frac{1}{2\pi} \left(\frac{c}{\rho} \right)^2 \frac{d^2I}{d\omega d\Omega} \Big|_{\omega=n\omega_0} \\ P_n &= \frac{1}{2\pi} \left(\frac{c}{\rho} \right)^2 \frac{dI}{d\omega} \Big|_{\omega=n\omega_0} \end{aligned} \right\} \quad (14.96)$$

These results have been compared with experiment at various energy synchrotrons.* The angular, polarization, and frequency distributions are all in good agreement with theory. Because of the broad frequency distribution shown in Fig. 14.11, covering the visible, ultraviolet, and X-ray regions, synchrotron radiation is a useful tool for the study of the optical properties of solids. Several synchrotron light facilities exist as parasitic installations attached to high-energy synchrotrons or storage rings whose main purpose is the study of fundamental particles. The article by Godwin† details synchrotron radiation from this point of view.

Synchrotron radiation has been observed in the astronomical realm associated with sunspots, the Crab nebula, and from the particle radiation belts of Jupiter. For the Crab nebula the radiation spectrum extends over a frequency range from radiofrequencies into the extreme ultraviolet, and shows very strong polarization. From detailed observations it can be concluded that electrons with energies ranging up to 10^{12} eV are emitting synchrotron radiation while moving in circular or helical orbits in a magnetic induction of the order of 10^{-3} gauss (see Problem 14.15). The radio emission at $\sim 10^3$ MHz from Jupiter comes from energetic electrons trapped in Van Allen belts at distances from a few to 30–100 radii (R_J) from Jupiter's surface. Data from a space vehicle (Pioneer 10, December 4, 1973 encounter with Jupiter) passing within $2.8R_J$ showed a roughly dipole magnetic field with a dipole moment of $4R_J^3$ gauss. Appreciable fluxes of trapped electrons with energies greater than 3 MeV and a few percent with energies greater than 50 MeV were observed. Taking 1 gauss as a typical field and 5 MeV as a typical energy, Eqs. (12.42) and (14.85) show that the spiraling radius is of the order of 100–200 meters, $\omega_0 \sim 2 \times 10^6 \text{ sec}^{-1}$, and that about 10^3 significant harmonics are radiated.

14.7 Thomson Scattering of Radiation

If a plane wave of monochromatic electromagnetic radiation is incident on a free particle of charge e and mass m , the particle will be accelerated and so emit radiation. This radiation will be emitted in directions other than that of the incident plane wave, but for nonrelativistic motion of the particle it will have the same frequency as the incident radiation. The whole process may be described as scattering of the incident radiation.

According to (14.20) the instantaneous power radiated into polarization state ϵ by a particle of charge e in nonrelativistic motion is

$$\frac{dP}{d\Omega} = \frac{e^2}{4\pi c^3} |\epsilon^* \cdot \dot{\mathbf{v}}|^2 \quad (14.97)$$

The acceleration is provided by the incident plane wave. If its propagation vector is \mathbf{k}_0 , and its polarization vector ϵ_0 , the electric field can be written

$$\mathbf{E}(\mathbf{x}, t) = \epsilon_0 E_0 e^{i\mathbf{k}_0 \cdot \mathbf{x} - i\omega t} \quad (14.98)$$

Then, from the force equation for nonrelativistic motion, we have the acceleration,

$$\dot{\mathbf{v}}(t) = \epsilon_0 \frac{e}{m} E_0 e^{i\mathbf{k}_0 \cdot \mathbf{x} - i\omega t} \quad (14.99)$$

If we assume that the charge moves a negligible part of a wavelength during one cycle of oscillation, the time average of $|\dot{\mathbf{v}}|^2$ is $\frac{1}{2} \text{Re} (\dot{\mathbf{v}} \cdot \dot{\mathbf{v}}^*)$. Then the average

power per unit solid angle can be expressed as

$$\left\langle \frac{dP}{d\Omega} \right\rangle = \frac{c}{8\pi} |E_0|^2 \left(\frac{e^2}{mc^2} \right)^2 |\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0|^2 \quad (14.100)$$

Since the process is most simply viewed as a scattering, it is convenient to introduce a scattering cross section, as in Chapter 9 defined by

$$\frac{d\sigma}{d\Omega} = \frac{\text{Energy radiated/unit time/unit solid angle}}{\text{Incident energy flux in energy/unit area/unit time}} \quad (14.101)$$

The incident energy flux is just the time-averaged Poynting vector for the plane wave, namely, $c |E_0|^2 / 8\pi$. Thus from (14.100) we obtain the differential scattering cross section,

$$\frac{d\sigma}{d\Omega} = \left(\frac{e^2}{mc^2} \right)^2 |\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0|^2 \quad (14.102)$$

The scattering geometry with a choice of polarization vectors for the outgoing wave is shown in Fig. 14.12. The polarization vector $\boldsymbol{\epsilon}_1$ is in the plane containing \mathbf{n} and \mathbf{k}_0 ; $\boldsymbol{\epsilon}_2$ is perpendicular to it. In terms of unit vectors parallel to the coordinate axes, $\boldsymbol{\epsilon}_1$ and $\boldsymbol{\epsilon}_2$ are

$$\boldsymbol{\epsilon}_1 = \cos \theta (\mathbf{e}_x \cos \phi + \mathbf{e}_y \sin \phi) - \mathbf{e}_z \sin \theta$$

$$\boldsymbol{\epsilon}_2 = -\mathbf{e}_x \sin \phi + \mathbf{e}_y \cos \phi$$

For an incident linearly polarized wave with polarization parallel to the x axis, the angular distribution summed over final polarizations is $(\cos^2 \theta \cos^2 \phi + \sin^2 \phi)$, while for polarization parallel to the y axis it is $(\cos^2 \theta \sin^2 \phi + \cos^2 \phi)$. For unpolarized incident radiation the scattering cross section is therefore

$$\frac{d\sigma}{d\Omega} = \left(\frac{e^2}{mc^2} \right)^2 \cdot \frac{1}{2} (1 + \cos^2 \theta) \quad (14.103)$$

Fig. 14.12

Fig. 14.13 Differential scattering cross section of unpolarized radiation by a point charged particle initially at rest in the laboratory. The solid curve is the classical Thomson result. The dashed curves are the quantum-mechanical results for a spinless particle, with the numbers giving the values of $\hbar\omega/mc^2$. For $\hbar\omega/mc^2 = 0.25, 1.0$ the dotted curves show the results for spin $\frac{1}{2}$ point particles (electrons).

This is called the *Thomson formula* for scattering of radiation by a free charge, and is appropriate for the scattering of X-rays by electrons or gamma rays by protons. The angular distribution is as shown in Fig. 14.13 by the solid curve. The total scattering cross section, called the *Thomson cross section*, is

$$\sigma_T = \frac{8\pi}{3} \left(\frac{e^2}{mc^2} \right)^2 \quad (14.104)$$

The Thomson cross section is equal to $0.665 \times 10^{-24} \text{ cm}^2$ for electrons. The unit of length, $e^2/mc^2 = 2.82 \times 10^{-13} \text{ cm}$, is called the *classical electron radius*, since a classical distribution of charge totaling the electronic charge must have a radius of this order if its electrostatic self-energy is to equal the electron mass.

The classical Thomson formula is valid only at low frequencies where the momentum of the incident photon can be ignored. When the photon's momentum $\hbar\omega/c$ becomes comparable to or larger than mc , modifications occur. These can be called quantum-mechanical effects since the concept of photons as massless particles with momentum and energy is certainly quantum mechanical (*pace*, Newton!), but granting that, most of the modifications are purely kinematical. The most important change is the one observed experimentally by Compton. The energy or momentum of the scattered photon is less than the

incident energy because the charged particle recoils during the collision. Applying two-body relativistic kinematics to the process, we find that the ratio of the outgoing to the incident wave number is given by the Compton formula,

$$\frac{k'}{k} = \frac{1}{1 + \frac{\hbar\omega}{mc^2} (1 - \cos \theta)}$$

where θ is the scattering angle in the laboratory (the rest frame of the target). A quantum-mechanical calculation of the scattering of photons by *spinless* point particles of charge e and mass m yields the cross section,

$$\frac{d\sigma}{d\Omega} = \left(\frac{e^2}{mc^2}\right)^2 \left(\frac{k'}{k}\right)^2 |\epsilon^* \cdot \epsilon_0|^2 \quad (14.105)$$

to be compared with the classical expression (14.102). In the radiation gauge the quantum-mechanical matrix element is the same as the classical amplitude. The factor $(k'/k)^2$ comes entirely from the phase space. Its presence causes the differential cross section to decrease relative to the Thomson result at large angles, as shown by the dashed curves in Fig. 14.13. Also shown in the figure by the dotted curves are the quantum-mechanical results for photon-electron scattering, that is, the scattering by a point spin $\frac{1}{2}$ particle described by the Dirac equation. The curves are generally similar to those for spinless particles, but are somewhat larger at large angles because of scattering by the electron's magnetic moment.* The integral over angles of (14.105) is elementary but slightly involved. We quote only the limiting forms for $\hbar\omega \ll mc^2$ and $\hbar\omega \gg mc^2$:

$$\frac{\sigma}{\sigma_T} = \begin{cases} 1 - 2 \frac{\hbar\omega}{mc^2} + \dots, & \hbar\omega \ll mc^2 \\ \frac{3}{4} \frac{mc^2}{\hbar\omega}, & \hbar\omega \gg mc^2 \end{cases} \quad (14.106)$$

For scattering by electrons the low frequency limit is the same, but at high frequencies there is an additional multiplicative factor, $[\frac{1}{4} + \frac{1}{2} \ln(2\hbar\omega/mc^2)]$.

For protons the departures from the Thomson formula occur at photon energies above about 100 MeV. This is far below the critical energy $\hbar\omega \sim Mc^2 \sim 1$ GeV which would be expected in analogy with the electron Compton effect. The reason is that a proton is not a point particle like the electron with nothing but electromagnetic interactions, but is a complex entity having a spread-out charge distribution with a radius of the order of 0.8×10^{-13} cm caused by strong

* For electrons the cross-section equivalent to (14.105) has $|\epsilon^* \cdot \epsilon_0|^2$ replaced by

$$|\epsilon^* \cdot \epsilon_0|^2 + \frac{(k - k')^2}{4kk'}$$

It is known as the *Klein-Nishina formula* for Compton scattering.

interactions with pi mesons. The departure (a rapid increase in cross section) from Thomson scattering occurs at photon energies of the order of the rest energy of the pi meson (140 MeV).

14.8 Scattering of Radiation by Quasi-Free Charges, Coherent and Incoherent Scattering

In the scattering of X-rays by atoms the angular distribution (14.103) is observed at wide angles, at least in light elements. But in the forward direction the scattering per electron increases rapidly to quite large values compared to the Thomson cross section. The reason is a coherent addition of the amplitudes from all electrons. From (14.18) it can be seen that the radiation field from a number of free nonrelativistic charged particles will be

$$\mathbf{E}_a = \frac{1}{c} \sum_j e_j \left[\frac{\mathbf{n} \times (\mathbf{n} \times \dot{\boldsymbol{\beta}}_j)}{R_j} \right]_{\text{ret}} \quad (14.107)$$

With (14.99) for the acceleration of the typical particle, we find

$$\mathbf{E}_a = \frac{E_0}{c^2} \mathbf{n} \times (\mathbf{n} \times \boldsymbol{\epsilon}_0) \sum_j \frac{e_j^2}{m_j} \frac{\exp \left[i \mathbf{k}_0 \cdot \mathbf{x}_j - i \omega \left(t - \frac{R_j}{c} \right) \right]}{R_j} \quad (14.108)$$

In calculating the radiation it is sufficient to approximate R_j in the exponent by the form (14.63). Then, in complete analogy with the steps from (14.97) to (14.102), we find the scattering cross section,

$$\frac{d\sigma}{d\Omega} = \left| \sum_j \frac{e_j^2}{m_j c^2} e^{i \mathbf{q} \cdot \mathbf{x}_j} \right|^2 \cdot |\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0|^2 \quad (14.109)$$

where

$$\mathbf{q} = \frac{\omega}{c} \mathbf{n} - \mathbf{k}_0 \quad (14.110)$$

is the vectorial change in wave number in the scattering.

Equation (14.109) applies to free charged particles instantaneously at positions \mathbf{x}_j . Electrons in atoms, for example, are not free. But if the frequency of the incident radiation is large compared to the characteristic frequencies of binding, the particles can be treated as free while being accelerated by a pulse of finite duration. Thus (14.109) can be applied to the scattering of high-frequency (compared to binding frequencies) radiation by bound charged particles. The only thing that remains before comparison with experiment is to average (14.109) over the positions of all the particles in the bound system. Thus the observable cross section for scattering is

$$\frac{d\sigma}{d\Omega} = \left\langle \left| \sum_j \frac{e_j^2}{m_j c^2} e^{i \mathbf{q} \cdot \mathbf{x}_j} \right|^2 \right\rangle |\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0|^2 \quad (14.111)$$

where the symbol $\langle \rangle$ means average over all possible values of \mathbf{x}_j .

The cross section (14.111) shows very different behavior, depending on the value of $|\mathbf{q}|$. The coordinates \mathbf{x}_i have magnitudes of the order of the linear dimensions of the bound system. If we call this dimension a , then the behavior of the cross section is very different in the two regions, $qa \ll 1$ and $qa \gg 1$. If the scattering angle is θ , the magnitude of q is $2k \sin(\theta/2)$. Thus the dividing line between the two domains occurs for angles such that

$$2ka \sin \frac{\theta}{2} \sim 1 \quad (14.112)$$

If the frequency is low enough so that $ka \ll 1$, then the limit $qa \ll 1$ will apply at all angles. But for frequencies where $ka \gg 1$, there will be a region of forward angles less than

$$\theta_c \sim \frac{1}{ka} \quad (14.113)$$

where the limit $qa \ll 1$ holds, and a region of wider angles where the limit $qa \gg 1$ applies.

For $qa \ll 1$, the arguments of exponents in (14.111) are all so small that the exponential factors can be approximated by unity. Then the differential cross section becomes

$$\lim_{qa \rightarrow 0} \frac{d\sigma}{d\Omega} = \left| \sum_i \frac{e_j^2}{m_j c^2} \right|^2 |\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0|^2 = Z^2 \left(\frac{e^2}{mc^2} \right)^2 |\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0|^2 \quad (14.114)$$

where the last form is appropriate for electrons in an atom of atomic number Z . This shows the coherent effect of all the particles, giving an intensity corresponding to the *square* of the number of particles times the intensity for a single particle.

In the opposite limit of $qa \gg 1$ the arguments of the exponents are large and widely different in value. Consequently the cross terms in the square of the sum will average to zero. Only the absolute squared terms will survive. Then the cross section takes the form:

$$\lim_{qa \rightarrow \infty} \frac{d\sigma}{d\Omega} = \sum_i \left(\frac{e_j^2}{m_j c^2} \right)^2 |\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0|^2 = Z \left(\frac{e^2}{mc^2} \right)^2 |\boldsymbol{\epsilon}^* \cdot \boldsymbol{\epsilon}_0|^2 \quad (14.115)$$

where again the final form is for electrons in an atom. This result corresponds to the incoherent superposition of scattering from the individual particles.

For the scattering of X-rays by atoms the critical angle (14.113) can be estimated, using (13.95) as the atomic radius. Then one finds the numerical value,

$$\theta_c \sim \frac{Z^{1/3}}{\hbar \omega (\text{keV})} \quad (14.116)$$

For angles less than θ_c the cross section rises rapidly to a value of the order of (14.114), while at wide angles it is given by (14.115), Z times the Thomson

result, or for high-frequency X-rays or gamma rays by the Klein-Nishina formula, shown in Fig. 14.13.

14.9 Transition Radiation

A charged particle in uniform motion in a straight line in free space does not radiate. It was shown in Section 13.5, however, that a particle moving at constant velocity can radiate if it is in a material medium and is moving with a speed greater than the phase velocity of light in that medium. This radiation, with its characteristic angle of emission, $\theta_c = \sec^{-1}(\beta\epsilon^{1/2})$, is Cherenkov radiation. There is another type of radiation, *transition radiation*, first noted by Ginsburg and Frank in 1946, that is emitted whenever a charged particle passes suddenly from one medium into another. Far from the boundary in the first medium the particle has certain fields characteristic of its motion and of that medium. Later, when it is deep in the second medium, it has fields appropriate to its motion and that medium. Even if the motion is uniform throughout, the initial and final fields will be different if the two media have different electromagnetic properties. Evidently the fields must reorganize themselves as the particle approaches and passes through the interface. In this process of reorganization some pieces of the fields are shaken off as transition radiation.

Important features of transition radiation can be understood without elaborate calculation.* We consider a relativistic particle with charge ze and speed $v = \beta c$ normally incident along the z axis from vacuum ($z < 0$) on a uniform semi-infinite medium ($z > 0$) with index of refraction $n(\omega)$, as indicated in Fig. 14.14. The moving fields of the charged particle induce a time-dependent polarization $\mathbf{P}(\mathbf{x}', t)$ in the medium. The polarization emits radiation. The radiated fields from different points in space combine coherently in the neighborhood of the path and for a certain depth in the medium, giving rise to transition radiation with a characteristic angular distribution and intensity.

The angular distribution and the *formation length* D are a direct consequence of the requirement of coherence for appreciable radiated intensity. The exciting fields of the incident particle are given by (11.152). The dependence at a point $\mathbf{x}' = (z', \rho', \phi')$ on inverse powers of $[\rho'^2 + \gamma^2(z' - vt)^2]$ implies that a Fourier component of frequency ω will (a) move in the z direction with velocity v and so have an amplitude proportional to $e^{i\omega z'/v}$, and (b) have significant magnitude radially from the path only out to distances of the order of $\rho'_{\max} \approx \gamma v/\omega$. On the other hand, the time-dependent polarization at \mathbf{x}' generates a wave whose form in the radiation zone is

$$A \frac{e^{ikr}}{r} \cdot e^{-ik(z' \cos \theta + \rho' \sin \theta \cos \phi')}$$

* The need for a qualitative discussion has been impressed on me by numerous questions from colleagues near and far and by V. F. Weisskopf on the occasion of a seminar by him where he presented a similar discussion.

Fig. 14.14 A charged particle of charge ze and velocity \mathbf{v} is normally incident along the z axis on a uniform semi-infinite dielectric medium occupying the half-space $z > 0$. The transition radiation is observed at angle θ with respect to the direction of motion of the particle, as specified by the wave vector \mathbf{k} and associated polarization vectors $\boldsymbol{\epsilon}_a$ and $\boldsymbol{\epsilon}_b$.

where A is proportional to the driving field of the incident particle, $k = n(\omega)\omega/c$ and it is assumed that the radiation is observed in the x - z plane and in the forward hemisphere. Appreciable coherent superposition from different points in the medium will occur provided the product of the driving fields of the particle and the generated wave does not change its phase significantly over the region. The relevant factor in the amplitude is

$$e^{i(\omega/v)z'} e^{-i(\omega/c)n(\omega) \cos \theta z'} e^{-i(\omega/c)n(\omega)\rho' \sin \theta \cos \phi'} = e^{i(\omega/c)(1/\beta - n(\omega) \cos \theta)z'} e^{-i(\omega/c)n(\omega)\rho' \sin \theta \cos \phi'}$$

In the radial direction coherence will be maintained only if the phase involving ρ' is unity or less in the region $0 < \rho' \leq \rho'_{\max}$ where the exciting field is appreciable. Thus radiation will not be appreciable unless

$$\frac{\omega}{c} n(\omega) \frac{\gamma v}{\omega} \sin \theta \leq 1$$

or

$$n(\omega)\gamma\theta \leq 1 \quad (14.117)$$

for $\gamma \gg 1$. The angular distribution is therefore confined to the forward cone, $\gamma\theta \lesssim 1$, as in all relativistic emission processes.

The z' -dependent factor in the amplitude is

$$e^{i(\omega/c)(1/\beta - n(\omega) \cos \theta)z'}$$

The depth $d(\omega)$ up to which coherence is maintained is therefore

$$\frac{\omega}{c} \left(\frac{1}{\beta} - n(\omega) \cos \theta \right) d(\omega) \approx 1$$

We approximate $n(\omega) \approx 1 - (\omega_p^2/2\omega^2)$ for frequencies above the optical region where Cherenkov radiation does not occur, $\beta^{-1} \approx 1 + 1/2\gamma^2$ for a relativistic particle, and $\cos \theta \approx 1$, to obtain

$$d(\nu) \approx \frac{2\gamma c/\omega_p}{\nu + \nu^{-1}} \quad (14.118)$$

where we have introduced a dimensionless frequency variable,

$$\nu = \frac{\omega}{\gamma\omega_p} \quad (14.119)$$

We define the *formation length* D as the largest value of $d(\nu)$ as a function of ν :

$$D = d(1) = \frac{\gamma c}{\omega_p} \quad (14.120)$$

For substances with densities of order of unity the plasma frequency is $\omega_p \approx 3 \times 10^{16} \text{ sec}^{-1}$, corresponding to an energy $\hbar\omega_p \approx 20 \text{ eV}$. Thus $c/\omega_p \approx 10^{-6} \text{ cm}$ and even for $\gamma \geq 10^3$ the formation length D is only tens of microns. In air at N.T.P. it is a factor of 30 larger because of the reduced density.

The coherence volume adjacent to the particle's path and the surface from which transition radiation of frequency ω comes is evidently

$$V(\omega) \sim \pi \rho_{\max}^2(\omega) d(\omega) \sim 2\pi\gamma \left(\frac{c}{\omega_p} \right)^3 \frac{1}{\nu(1+\nu^2)}$$

This volume decreases in size rapidly for $\nu > 1$. We can therefore expect that in the absence of compensating factors the spectrum of transition radiation will extend up to, but not appreciably beyond, $\nu \approx 1$.

We have obtained some insight into the mechanism of transition radiation and its main features. It is confined to small angles in the forward direction ($\gamma\theta \lesssim 1$). It is produced by coherent radiation of the time-varying polarization in a small volume adjacent to the particle's path and at depths into the medium up to the formation length D . Its spectrum extends up to frequencies of the order of $\omega \sim \gamma\omega_p$. It is possible to continue these qualitative arguments and obtain an estimate of the total energy radiated, but the exercise begins to have the appearance of virtuosity based on hindsight. Instead, we turn to an actual calculation of the phenomenon.

An exact calculation of transition radiation is complicated. Some references are given at the end of the chapter. We content ourselves with an approximate

calculation that is adequate for most applications and is physically transparent. It is based on the observation that for frequencies above the optical resonance region the index of refraction is not far from unity. The incident particle's fields at such frequencies are not significantly different in the medium from in vacuum. This means that the Fourier component of the induced polarization $\mathbf{P}(\mathbf{x}', \omega)$ can be evaluated approximately by

$$\mathbf{P}(\mathbf{x}', \omega) = \left[\frac{\epsilon(\omega) - 1}{4\pi} \right] \mathbf{E}_i(\mathbf{x}', \omega) \quad (14.121)$$

where \mathbf{E}_i is the Fourier transform of the electric field of the incident particle in vacuum. The *propagation* of the wave radiated by the polarization must be described properly, however, with the wave number $k = \omega n(\omega)/c$ appropriate to the medium. This is because phase differences are important, as already seen in the qualitative discussion.

The dipole radiation field from the polarization $\mathbf{P}(\mathbf{x}', \omega) d^3x'$ in the volume element d^3x' at \mathbf{x}' is, according to (9.18),

$$d\mathbf{E}_{\text{rad}} = \frac{e^{ikR}}{R} (\mathbf{k} \times \mathbf{P}) \times \mathbf{k} d^3x'$$

where \mathbf{k} is the wave vector in the direction of observation and $R \approx r - \hat{\mathbf{k}} \cdot \mathbf{x}'$. With the substitution of (14.121) and an integration over the half-space $z' > 0$, the total radiated field at frequency ω is

$$\mathbf{E}_{\text{rad}} = \frac{e^{ikr}}{r} \left[\frac{\epsilon(\omega) - 1}{4\pi} \right] k^2 \int_{z' > 0} (\hat{\mathbf{k}} \times \mathbf{E}_i) \times \hat{\mathbf{k}} e^{-i\mathbf{k} \cdot \mathbf{x}'} d^3x'$$

With the approximation,

$$\epsilon(\omega) \approx 1 - \frac{\omega_p^2}{\omega^2} \quad (14.122)$$

the radiated field for $\omega \gg \omega_p$ becomes

$$\mathbf{E}_{\text{rad}} \approx \frac{e^{ikr}}{r} \left(\frac{-\omega_p^2}{4\pi c^2} \right) \int_{z' > 0} (\hat{\mathbf{k}} \times \mathbf{E}_i) \times \hat{\mathbf{k}} e^{-i\mathbf{k} \cdot \mathbf{x}'} d^3x' \quad (14.123)$$

From (14.52) and (14.60) this means that the energy radiated has the differential spectrum in an angle and energy,

$$\frac{d^2 I}{d\omega d\Omega} = \frac{c}{32\pi^3} \left(\frac{\omega_p}{c} \right)^4 \left| \int_{z' > 0} [\hat{\mathbf{k}} \times \mathbf{E}_i(\mathbf{x}, \omega)] \times \hat{\mathbf{k}} e^{-i\mathbf{k} \cdot \mathbf{x}'} d^3x' \right|^2 \quad (14.124)$$

Note that the driving fields \mathbf{E}_i are defined by the Fourier transform (14.54) of the fields of Section 11.10, already used in Section 13.2. In our approximation it is not necessary to use the more elaborate fields of Section 13.4. In the notation of Fig. 14.14 the incident fields are

$$\begin{aligned} E_\rho(\mathbf{x}, \omega) &= \sqrt{\frac{2}{\pi}} \frac{ze\omega}{\gamma v^2} e^{i\omega z/v} K_1\left(\frac{\omega\rho}{\gamma v}\right) \\ E_z(\mathbf{x}, \omega) &= -i\sqrt{\frac{2}{\pi}} \frac{ze\omega}{\gamma^2 v^2} e^{i\omega z/v} K_0\left(\frac{\omega\rho}{\gamma v}\right) \end{aligned} \quad (14.125)$$

The integral in (14.124) can be evaluated as follows. We first exploit the fact that the z -dependence of \mathbf{E}_i is only via the factor $e^{i\omega z/v}$, and write

$$\begin{aligned}\mathbf{F} &\equiv \int_{z>0} [\hat{\mathbf{k}} \times \mathbf{E}_i(\mathbf{x}, \omega)] \times \hat{\mathbf{k}} e^{-i\hat{\mathbf{k}} \cdot \mathbf{x}} d^3x \\ &= \iint dx dy [\hat{\mathbf{k}} \times \mathbf{E}_i]_{z=0} \times \hat{\mathbf{k}} e^{-ik \sin \theta x} \int_0^\infty dz e^{i(\omega/v - k \cos \theta)z} \\ &= \frac{i}{\left(\frac{\omega}{v} - k \cos \theta\right)} (1 - e^{i(\omega/v - k \cos \theta)Z}) \iint dx dy [\hat{\mathbf{k}} \times \mathbf{E}_i]_{z=0} \times \hat{\mathbf{k}} e^{-ik \sin \theta x}\end{aligned}$$

The upper limit Z on the z integration is a formal device to show that the contributions from different z values add constructively and cause the amplitude to grow until $Z \geq D$. Beyond the depth D the rapidly rotating phase prevents further enhancement. For effectively semi-infinite media (slabs of thickness large compared with D) we drop the oscillating exponential in Z on physical grounds* and obtain, for a *single interface*,

$$\mathbf{F} = \frac{i}{\left(\frac{\omega}{v} - k \cos \theta\right)} \iint dx dy e^{-ik \sin \theta x} [\hat{\mathbf{k}} \times \mathbf{E}_i]_{z=0} \times \hat{\mathbf{k}}$$

The electric field transverse to $\hat{\mathbf{k}}$ can be expressed in terms of the components E_ρ , E_z and the polarization vectors \mathbf{e}_a and \mathbf{e}_b shown in Fig. 14.14 as

$$[\hat{\mathbf{k}} \times \mathbf{E}_i] \times \hat{\mathbf{k}} = (E_\rho \cos \theta \cos \phi - E_z \sin \theta) \mathbf{e}_a + E_\rho \sin \phi \mathbf{e}_b$$

where θ is the polar angle of $\hat{\mathbf{k}}$ and the prime has been dropped from the azimuthal angle of integration. The component parallel to \mathbf{e}_b integrates to zero because it is odd in y . Thus, substituting from (14.125), we have

$$\begin{aligned}\mathbf{F} &= \frac{i\mathbf{e}_a}{\left(\frac{\omega}{v} - k \cos \theta\right)} \iint dx dy e^{-ik \sin \theta x} \left[\cos \theta \frac{x}{\sqrt{x^2 + y^2}} E_\rho - \sin \theta E_z \right]_{z=0} \\ &= \frac{i\mathbf{e}_a}{\left(\frac{\omega}{v} - k \cos \theta\right)} \sqrt{\frac{2}{\pi}} \frac{ze\omega}{\gamma v^2} \iint dx dy e^{-ik \sin \theta x} \\ &\quad \left[\cos \theta \frac{x}{\sqrt{x^2 + y^2}} K_1\left(\frac{\omega}{\gamma v} \sqrt{x^2 + y^2}\right) + i \frac{\sin \theta}{\gamma} K_0\left(\frac{\omega}{\gamma v} \sqrt{x^2 + y^2}\right) \right]\end{aligned}$$

The first term can be transformed by an integration by parts in x , using

$$\frac{x}{\sqrt{x^2 + y^2}} K_1\left(\frac{\omega}{\gamma v} \sqrt{x^2 + y^2}\right) = -\frac{\gamma v}{\omega} \frac{\partial}{\partial x} K_0\left(\frac{\omega}{\gamma v} \sqrt{x^2 + y^2}\right)$$

* A less cavalier treatment of the dependence on thickness is necessary for foils that are not thick compared to D , or when a stack of foils is employed. See Problems 14.18 and 14.19.

Fig. 14.15 Angular distributions of transition radiation at $\nu = 0.1$, $\nu = 1$ and $\nu \gg 1$. The solid curves are the normalized angular distributions, that is, the ratio of (14.129) to (14.132). The dashed curve is ν^4 times that ratio in the limit $\nu \rightarrow \infty$.

so that

$$\mathbf{F} = \epsilon_a \sqrt{\frac{2}{\pi}} \frac{ze \sin \theta}{v \left(\frac{\omega}{v} - k \cos \theta \right)} \left(k \cos \theta - \frac{\omega}{v\gamma^2} \right) \iint dx dy e^{-ik \sin \theta x} K_0 \left(\frac{\omega}{\gamma v} \sqrt{x^2 + y^2} \right)$$

The remaining integral can be evaluated from the cosine transform,

$$\int_0^\infty K_0(\beta \sqrt{z^2 + t^2}) \cos(\alpha z) dz = \frac{\pi}{2\sqrt{\alpha^2 + \beta^2}} \exp(-|t|\sqrt{\alpha^2 + \beta^2}) \quad (14.126)$$

The result for \mathbf{F} is

$$\mathbf{F} = \epsilon_a \frac{2\sqrt{2\pi} ze \sin \theta \left(k \cos \theta - \frac{\omega}{v\gamma^2} \right)}{v \left(\frac{\omega}{v} - k \cos \theta \right) \left(\frac{\omega^2}{\gamma^2 v^2} + k^2 \sin^2 \theta \right)} \quad (14.127)$$

In the approximation of relativistic motion ($\gamma \gg 1$), small angles ($\theta \ll 1$) and high

frequencies ($\omega \gg \omega_p$), this becomes

$$\mathbf{F} \approx \epsilon_a 4\sqrt{2\pi} \frac{ze}{c} \left(\frac{c}{\omega_p}\right)^2 \frac{\gamma}{\nu^2} \frac{\sqrt{\eta}}{\left(1 + \frac{1}{\nu^2} + \eta\right)(1 + \eta)} \quad (14.128)$$

where ν is the dimensionless frequency variable (14.119) and $\eta = (\gamma\theta)^2$ is an appropriate angular variable. With $d\Omega = d\phi d(\cos \theta) \approx d\phi d\eta/2\gamma^2$, the energy distribution in ν and η is

$$\begin{aligned} \frac{d^2 I}{d\nu d\eta} &= \frac{\pi}{\gamma^2} \cdot \gamma\omega_p \cdot \frac{d^2 I}{d\omega d\Omega} \\ &\approx \frac{z^2 e^2 \gamma\omega_p}{\pi c} \cdot \left[\frac{\eta}{\nu^4 \left(1 + \frac{1}{\nu^2} + \eta\right)^2 (1 + \eta)^2} \right] \end{aligned} \quad (14.129)$$

Angular distributions for fixed ν values are shown in Fig. 14.15. At low frequencies the spectrum peaks at $\eta \approx 1$ and then falls relatively slowly as η^{-1} until the value $\eta = \nu^{-2}$ is reached. Then it falls off as η^{-3} . For $\nu \geq 1$, the spectrum peaks at $\eta \approx \frac{1}{3}$ and falls at η^{-3} for $\eta \gg 1$. At $\eta = 0$ the denominator in (14.129) is $(1 + \nu^2)^2$, showing that for $\nu \gg 1$ there is negligible intensity at any angle [compare the coherence volume $V(\omega)$, above].

The energy spectrum, integrated over the angular variable η , is

$$\frac{dI}{d\nu} = \frac{z^2 e^2 \gamma\omega_p}{\pi c} \left[(1 + 2\nu^2) \ln \left(1 + \frac{1}{\nu^2} \right) - 2 \right] \quad (14.130)$$

It has the small and large ν limits,

$$\frac{dI}{d\nu} \approx \frac{z^2 e^2 \gamma\omega_p}{\pi c} \begin{cases} 2 \ln(1/\nu^2), & \nu \ll 1 \\ \frac{1}{6\nu^4}, & \nu \gg 1 \end{cases} \quad (14.131)$$

The energy spectrum is shown on a log-log plot in Fig. 14.16. The spectrum diverges logarithmically at low frequencies, where our approximate treatment fails in any event, but it has a finite integral. The total energy emitted in transition radiation per interface is

$$I = \int_0^\infty \frac{dI}{d\nu} d\nu = \frac{z^2 e^2 \gamma\omega_p}{3c} = \frac{z^2}{3(137)} \gamma \hbar\omega_p \quad (14.132)$$

From Fig. 14.16 we can estimate that about half of the energy is emitted in the range $0.1 \leq \nu \leq 1$. In quantum language, we say that an appreciable fraction of the energy appears as comparatively energetic photons. For example, with $\gamma = 10^3$ and $\hbar\omega_p = 20$ eV, these quanta are in the soft X-ray region of 2 to 20 keV.

The presence of the factor of γ in (14.132) makes transition radiation attractive as a mechanism for the identification of particles, and perhaps even

Fig. 14.16 Normalized frequency distribution $(1/I)(dI/d\nu)$ of transition radiation as a function of $\nu = \omega/\gamma\omega_p$. The dashed curves are the two approximate expressions in (14.131).

measurement of their energies, at very high energies where other means are unavailable. The presence of the numerical factor $1/(3 \times 137)$ means that the probability of energetic photon emission per transit of an interface is very small. It is necessary to utilize a stack of many foils with gaps between. The foils can be quite thin, needing only to be thick compared to a formation length D (14.120). Then a particle traversing each foil will emit *twice* (14.132) in transition radiation (see Problem 14.18). A typical set-up might involve 200 Mylar foils of thickness $(1-5) \times 10^{-3}$ cm, with spacings from 2×10^{-2} cm to 0.4 cm. The coherent superposition of the fields from the different interfaces, two for each foil, causes a modulation of the energy and angular distributions (see Problem 14.19). Problems of tolerances, absorption of the soft X-rays in the stack, and their reliable detection in the presence of backgrounds make difficult the construction

of a useful instrument. Considerable research and development, begun in the U.S.S.R., has been done and continues.*

REFERENCES AND SUGGESTED READING

The radiation by accelerated charges is at least touched on in all electrodynamics textbooks, although the emphasis varies considerably. The relativistic aspects are treated in more or less detail in

- Iwanenko and Sokolow, Sections 39–43,
- Landau and Lifshitz, *Classical Theory of Fields*, Chapters 8 and 9,
- Panofsky and Phillips, Chapters 18 and 19,
- Sommerfeld, *Electrodynamics*, Sections 29 and 30.

Extensive calculations of the radiation emitted by relativistic particles, anticipating many results rederived in the period 1940–1950, are presented in the interesting monograph by

Schott.

Synchrotron radiation has applications to solid state physics, plasmas, and in astrophysics.

A detailed description of the synchrotron as a light source is contained in
Godwin (*op. cit.*).

Plasma physics applications are discussed by

Bekefi

while astrophysical problems are treated in detail in

- A. G. Pacholczyk, *Radio Astrophysics*, Freeman, San Francisco (1970),
with numerous references to the research literature at the end of each chapter.

The scattering of radiation by charged particles is presented clearly by

- Landau and Lifshitz, *Classical Theory of Fields*, Sections 9.11–9.13, and
Electrodynamics of Continuous Media, Chapters XIV and XV.

Transition radiation is reviewed with extensive bibliographies by

- I. M. Frank, *Usp. Fiz. Nauk.* **87**, 189 (1965) [transl. *Sov. Phys. Uspekhi* **8**, 729 (1966)],

PROBLEMS

14.1 Verify by explicit calculation that the Liénard-Wiechert expressions for all components of \mathbf{E} and \mathbf{B} for a particle moving with constant velocity agree with the ones obtained in the text by means of a Lorentz transformation. Follow the general method at the end of Section 14.1.

14.2 Using the Liénard-Wiechert fields, discuss the time-average power radiated per unit solid angle in nonrelativistic motion of a particle with charge e , moving

(a) along the z axis with instantaneous position $z(t) = a \cos \omega_0 t$,

(b) in a circle of radius R in the x - y plane with constant angular frequency ω_0 .

Sketch the angular distribution of the radiation and determine the total power radiated in each case.

14.3 A nonrelativistic particle of charge ze , mass m , and kinetic energy E makes a head-on collision with a fixed central force field of finite range. The interaction is repulsive and described by a potential $V(r)$, which becomes greater than E at close distances.

(a) Show that the total energy radiated is given by

$$\Delta W = \frac{4}{3} \frac{z^2 e^2}{m^2 c^3} \sqrt{\frac{m}{2}} \int_{r_{\min}}^{\infty} \left| \frac{dV}{dr} \right|^2 \frac{dr}{\sqrt{V(r_{\min}) - V(r)}}$$

where r_{\min} is the closest distance of approach in the collision.

(b) If the interaction is a Coulomb potential $V(r) = zZe^2/r$, show that the total energy radiated is

$$\Delta W = \frac{8}{45} \frac{z m v_0^5}{Z c^3}$$

where v_0 is the velocity of the charge at infinity.

14.4 A particle of mass m , charge q , moves in a plane perpendicular to a uniform, static, magnetic induction B .

(a) Calculate the total energy radiated per unit time, expressing it in terms of the constants already defined and the ratio γ of the particle's total energy to its rest energy.

(b) If at time $t=0$ the particle has a total energy $E_0 = \gamma_0 mc^2$, show that it will have energy $E = \gamma mc^2 < E_0$ at a time t , where

$$t \approx \frac{3m^3 c^5}{2q^4 B^2} \left(\frac{1}{\gamma} - \frac{1}{\gamma_0} \right)$$

provided $\gamma \gg 1$.

(c) If the particle is initially nonrelativistic and has a kinetic energy ϵ_0 at $t=0$, what is its kinetic energy at time t ?

(d) If the particle is actually trapped in the magnetic dipole field of the earth and is spiraling back and forth along a line of force, does it radiate more energy while near the equator, or while near its turning points? Why? Make quantitative statements if you can.

14.5 As in Problem 14.2a a charge e moves in simple harmonic motion along the z axis, $z(t') = a \cos(\omega_0 t')$.

(a) Show that the instantaneous power radiated per unit solid angle is:

$$\frac{dP(t')}{d\Omega} = \frac{e^2 c \beta^4}{4\pi a^2} \frac{\sin^2 \theta \cos^2(\omega_0 t')}{(1 + \beta \cos \theta \sin \omega_0 t')^5}$$

where $\beta = a\omega_0/c$.

(b) By performing a time averaging, show that the average power per unit solid angle is:

$$\frac{dP}{d\Omega} = \frac{e^2 c \beta^4}{32\pi a^2} \left[\frac{4 + \beta^2 \cos^2 \theta}{(1 - \beta^2 \cos^2 \theta)^{7/2}} \right] \sin^2 \theta$$

(c) Make rough sketches of the angular distribution for nonrelativistic and relativistic motion.

14.6 Show explicitly by use of the Poisson sum formula or other means that, if the motion of a radiating particle repeats itself with periodicity T , the continuous frequency spectrum becomes a discrete spectrum containing frequencies that are integral multiples of the fundamental. Show that a general expression for the time-average power radiated per unit solid angle in each multiple m of the fundamental frequency $\omega_0 = 2\pi/T$ is:

$$\frac{dP_m}{d\Omega} = \frac{e^2 \omega_0^4 m^2}{(2\pi c)^3} \left| \int_0^{2\pi/\omega_0} \mathbf{v}(t) \times \mathbf{n} \exp \left[im\omega_0 \left(t - \frac{\mathbf{n} \cdot \mathbf{x}(t)}{c} \right) \right] dt \right|^2$$

14.7 (a) Show that for the simple harmonic motion of a charge discussed in Problem 14.5 the average power radiated per unit solid angle in the m th harmonic is:

$$\frac{dP_m}{d\Omega} = \frac{e^2 c \beta^2}{2\pi a^2} m^2 \tan^2 \theta J_m^2(m\beta \cos \theta)$$

(b) Show that in the nonrelativistic limit the total power radiated is all in the fundamental and has the value:

$$P \approx \frac{2}{3} \frac{e^2}{c^3} \omega_0^4 \overline{a^2}$$

where $\overline{a^2}$ is the mean square amplitude of oscillation.

14.8 A particle of charge e moves in a circular path of radius R in the x - y plane with a constant angular velocity ω_0 .

(a) Show that the exact expression for the angular distribution of power radiated into the m th multiple of ω_0 is:

$$\frac{dP_m}{d\Omega} = \frac{e^2 \omega_0^4 R^2}{2\pi c^3} m^2 \left\{ \left[\frac{dJ_m(m\beta \sin \theta)}{d(m\beta \sin \theta)} \right]^2 + \frac{\cot^2 \theta}{\beta^2} J_m^2(m\beta \sin \theta) \right\}$$

where $\beta = \omega_0 R/c$, and $J_m(x)$ is the Bessel function of order m .

(b) Assume nonrelativistic motion and obtain an approximate result for $dP_m/d\Omega$. Show that the results of Problem 14.2b are obtained in this limit.

(c) Assume extreme relativistic motion and obtain the results found in the text for a relativistic particle in instantaneously circular motion. (Watson, pp. 79, 249, may be of assistance to you.)

14.9 A particle of charge e and mass m moves relativistically in a helical path in a uniform magnetic field \mathbf{B} . The pitch angle of the helix is α ($\alpha = 0$ corresponds to circular motion).

(a) By arguments similar to those of Section 14.4 show that an observer far from the helix would detect radiation with a fundamental frequency

$$\omega_0 = \frac{\omega_B}{\cos^2 \alpha}$$

and that the spectrum would extend up to frequencies of the order of

$$\omega_c = \gamma^3 \omega_B \cos \alpha$$

where $\omega_B = eB/\gamma mc$. (Take care in determining the radius of curvature ρ of the helical path.)

(b) From part (a) and the results of Section 14.6 show that the power radiated per unit solid angle and per unit circular frequency interval is

$$\frac{d^2 P}{d\omega d\Omega} \simeq \frac{e^2 \gamma^2}{6\pi^3 c} \frac{\omega_B}{\cos^2 \alpha} \left(\frac{\omega}{\omega_c} \right)^2 (1 + \gamma^2 \psi^2) \left[K_{2/3}^2(\xi) + \frac{\gamma^2 \psi^2}{1 + \gamma^2 \psi^2} K_{1/3}^2(\xi) \right]$$

where ω_B and ω_c are defined above, $\xi = (\omega/3\omega_c)(1 + \gamma^2 \psi^2)^{3/2}$, and ψ is the angle of observation measured relative to the particle's velocity vector, as in Fig. 14.9.

14.10 Bohr's correspondence principle states that in the limit of large quantum numbers the classical power radiated in the fundamental is equal to the product of the quantum energy ($\hbar\omega_0$) and the reciprocal mean lifetime of the transition from principal quantum number n to $(n-1)$.

(a) Using nonrelativistic approximations, show that in a hydrogen-like atom the transition probability (reciprocal mean lifetime) for a transition from a circular orbit of principal quantum number n to $(n-1)$ is given classically by

$$\frac{1}{\tau} = \frac{2}{3} \frac{e^2}{\hbar c} \left(\frac{Ze^2}{\hbar c} \right)^4 \frac{mc^2}{\hbar} \frac{1}{n^5}$$

(b) For hydrogen compare the classical value from (a) with the correct quantum-mechanical results for the transitions $2p \rightarrow 1s$ (1.6×10^{-9} sec), $4f \rightarrow 3d$ (7.3×10^{-8} sec), $6h \rightarrow 5g$ (6.1×10^{-7} sec).

14.11 Periodic motion of charges gives rise to a discrete frequency spectrum in multiples of the basic frequency of the motion. Appreciable radiation in multiples of the fundamental can occur because of relativistic effects (Problems 14.7 and 14.8) even though the components of velocity are truly *sinusoidal*, or it can occur if the components of velocity are not sinusoidal, even though periodic. An example of this latter motion is an electron undergoing nonrelativistic elliptic motion in a hydrogen atom.

The orbit can be specified by the parametric equations

$$x = a(\cos u - \epsilon)$$

$$y = a\sqrt{1 - \epsilon^2} \sin u$$

where

$$\omega_0 t = u - \epsilon \sin u$$

a is the semimajor axis, ϵ is the eccentricity, ω_0 is the orbital frequency, and u is an angle related to the polar angle θ of the particle by $\tan(u/2) = \sqrt{(1 - \epsilon)/(1 + \epsilon)} \tan(\theta/2)$. In terms of the binding energy B and the angular momentum L , the various constants are

$$a = \frac{e^2}{2B}, \quad \epsilon = \sqrt{1 - \frac{2BL^2}{me^4}}, \quad \omega_0^2 = \frac{8B^3}{me^4}$$

(a) Show that the power radiated in the k th multiple of ω_0 is

$$P_k = \frac{4e^2}{3c^3} (k\omega_0)^4 a^2 \left\{ \frac{1}{k^2} \left[(J'_k(k\epsilon))^2 + \left(\frac{1-\epsilon^2}{\epsilon^2} \right) J_k^2(k\epsilon) \right] \right\}$$

where $J_k(x)$ is a Bessel function of order k .

(b) Verify that for circular orbits the general result (a) agrees with part (a) of Problem 14.10.

14.12 Instead of a single charge e moving with constant velocity ω_0 in a circular path of radius R , as in Problem 14.8, a set of N such charge moves with fixed relative positions around the same circle.

(a) Show that the power radiated into the m th multiple of ω_0 is

$$\frac{dP_m(N)}{d\Omega} = \frac{dP_m(1)}{d\Omega} F_m(N)$$

where $dP_m(1)/d\Omega$ is the result of part (a) in Problem 14.8, and

$$F_m(N) = \left| \sum_{j=1}^N e^{im\theta_j} \right|^2$$

θ_j being the angular position of the j th charge at $t=t_0$.

(b) Show that, if the charges are uniformly spaced around the circle, energy is radiated only into multiples of $N\omega_0$, but with an intensity N^2 times that for a single charge. Give a qualitative explanation of these facts.

(c) Without detailed calculations show that for nonrelativistic motion the dependence on N of the total power radiated is dominantly as β^{2N} , so that in the limit $N \rightarrow \infty$ no radiation is emitted.

(d) By arguments like those of (c) show that for relativistic particles the radiated power varies with N mainly as $\exp(-2N/3\gamma^3)$ for $N \gg \gamma^3$, so that again in the limit $N \rightarrow \infty$ no radiation is emitted.

(e) What relevance have the results of (c) and (d) to the radiation properties of a steady current in a loop?

14.13 As an idealization of steady-state currents flowing in a circuit, consider a system of N identical charges q moving with constant speed v (but subject to accelerations) in an arbitrary closed path. Successive charges are separated by a constant small interval Δ .

Starting with the Liénard-Wiechert fields for each particle, and making no assumptions concerning the speed v relative to the velocity of light show that, in the limit $N \rightarrow \infty$, $q \rightarrow 0$, and $\Delta \rightarrow 0$, but $Nq = \text{constant}$ and $q/\Delta = \text{constant}$, no radiation is emitted by the system and the electric and magnetic fields of the system are the usual static values.

(Note that for a real circuit the stationary positive ions in the conductors will produce an electric field which just cancels that due to the moving charges.)

14.14 Assume that the instantaneous power spectrum radiated by an electron in a synchrotron is given by

$$P(\omega, t) \approx \frac{2}{\pi} \frac{e^2}{\rho} \gamma(t) \left(\frac{\omega}{\omega_c} \right)^{1/3} e^{-2\omega/\omega_c}$$

where $\omega_c = 3\omega_0\gamma^3(t)$.

(a) If the electrons increase their energy approximately linearly during one cycle of

operation, show that the power spectrum, averaged over one cycle of operation, is

$$\langle P(\omega, t) \rangle = \frac{2^{2/3}}{3\pi} \frac{e^2}{\rho} \gamma_{\max} x^{2/3} \int_x^\infty \frac{e^{-y}}{y^{4/3}} dy$$

where $x = 2\omega/\omega_{c\max}$

(b) Determine limiting forms for the spectrum when $x \ll 1$ and $x \gg 1$.

(c) By finding tables of the integral (it is an incomplete gamma function) or by graphical integration for $x = 0.1, 0.5, 1.0, 1.5$, determine numerically the spectrum, plot it as a function of $\log[\omega/\omega_{c\max}]$, and compare it with the curves given by Elder, Langmuir, and Pollock, *Phys. Rev.*, **74**, 52 (1948), Fig. 1.

- 14.15** (a) Within the framework of approximations of Section 14.6, show that, for a relativistic particle moving in a path with instantaneous radius of curvature ρ , the frequency-angle spectra of radiations with positive and negative helicity are

$$\frac{d^2 I_\pm}{d\omega d\Omega} = \frac{e^2}{6\pi^2 c} \left(\frac{\omega\rho}{c} \right)^2 \left(\frac{1}{\gamma^2} + \theta^2 \right)^2 \left| K_{2/3}(\xi) \pm \frac{\theta}{\left(\frac{1}{\gamma^2} + \theta^2 \right)^{1/2}} K_{1/3}(\xi) \right|^2$$

(b) From the formulas of Section 14.6 and (a) above, discuss the polarization of the total radiation emitted as a function of frequency and angle. In particular, determine the state of polarization at (1) high frequencies ($\omega > \omega_c$) for all angles, (2) intermediate and low frequencies ($\omega < \omega_c$) for large angles, (3) intermediate and low frequencies at very small angles.

(c) See the paper by P. Joos, *Phys. Rev. Letters*, **4**, 558 (1960), for experimental comparison.

- 14.16** Consider the synchrotron radiation from the Crab nebula. Electrons with energies up to 10^{13} eV move in a magnetic field of the order of 10^{-4} gauss.

(a) For $E = 10^{13}$ eV, $B = 3 \times 10^{-4}$ gauss, calculate the orbit radius ρ , the fundamental frequency $\omega_0 = c/\rho$, and the critical frequency ω_c . What is the energy $\hbar\omega_c$ in keV?

(b) Show that for a relativistic electron of energy E in a constant magnetic field the power spectrum of synchrotron radiation can be written

$$P(E, \omega) = \text{const} \left(\frac{\omega}{E^2} \right)^{1/3} f\left(\frac{\omega}{\omega_c} \right)$$

where $f(x)$ is a cutoff function having the value unity at $x = 0$ and vanishing rapidly for $x \gg 1$ [e.g., $f = \exp(-2\omega/3\omega_c)$, as in Problem 14.14], and $\omega_c = (eB/mc)(E/mc^2)^2 \cos \theta$, where θ is the pitch angle of the helical path. Cf. Prob. 14.9(a).

(c) If electrons are distributed in energy according to the spectrum $N(E) dE \sim E^{-n} dE$, show that the synchrotron radiation has the power spectrum

$$\langle P(\omega) \rangle d\omega \sim \omega^{-\alpha} d\omega$$

where $\alpha = (n-1)/2$.

(d) Observations on the radiofrequency and optical continuous spectrum from the Crab nebula show that on the frequency interval from $\omega \sim 10^8 \text{ sec}^{-1}$ to $\omega \sim 6 \times 10^{15} \text{ sec}^{-1}$ the constant $\alpha \approx 0.35$. At frequencies above 10^{18} sec^{-1} the spectrum of radiation falls steeply with $\alpha \geq 1.5$. Determine the index n for the electron-energy spectrum, as well as an upper cutoff for that spectrum. Is this cutoff consistent with the numbers of part (a)?

(e) The half-life of a particle emitting synchrotron radiation is defined as the time taken for it to lose one half of its initial energy. From the result of Problem 14.4(b) find

a formula for the half-life of an electron in years when B is given in milligauss and E in GeV. What is the half-life using the numbers from part (a)? How does this compare with the known lifetime of the Crab nebula? Must the energetic electrons be continually replenished? From what source?

- 14.17** A relativistic particle of charge ze moves along the z axis with a constant speed βc . The half-space $z \leq 0$ is filled with a uniform isotropic dielectric medium with plasma frequency ω_1 , and the space $z > 0$ with a similar medium whose plasma frequency is ω_2 . Discuss the emission of transition radiation as the particle traverses the interface, using the approximation of Section 14.9.

(a) Show that the radiation intensity per unit circular frequency interval and per unit solid angle is given approximately by

$$\frac{d^2 I}{d\omega d\Omega} \approx \frac{z^2 e^2 \theta^2}{\pi^2 c} \left| \frac{1}{\frac{1}{\gamma^2} + \frac{\omega_1^2}{\omega^2} + \theta^2} - \frac{1}{\frac{1}{\gamma^2} + \frac{\omega_2^2}{\omega^2} + \theta^2} \right|^2$$

where θ is the angle of emission relative to the velocity of the particle and $\gamma = (1 - \beta^2)^{-1/2}$.

(b) Show that the total energy radiated is

$$I \approx \frac{z^2 e^2}{3c} \cdot \frac{(\omega_1 - \omega_2)^2}{(\omega_1 + \omega_2)^2} \gamma$$

- 14.18** Consider the transition radiation emitted by a relativistic particle traversing a dielectric foil of thickness a perpendicular to its path. Assuming that $|(n(\omega) - 1)/(n(\omega) + 1)|$ is very small so that reflections can be ignored, show that the differential angular and frequency spectrum is given by the single-interface result (14.129) times the factor,

$$\mathcal{F} = 4 \sin^2 \Theta, \text{ with } \Theta = v \left(1 + \frac{1}{v^2} + \eta \right) \frac{a}{4D}$$

Here $D = \gamma c / \omega_p$ is the formation length, $v = \omega / \gamma \omega_p$, and $\eta = (\gamma \theta)^2$. Provided $a \gg D$, the factor \mathcal{F} oscillates extremely rapidly in angle or frequency, averaging to $\langle \mathcal{F} \rangle = 2$. For such foils the smoothed intensity distribution is just twice that for a single interface. Frequency distribution for different values of $\Gamma = 2D/a$ are displayed in Fig. 1 of G. B. Yodh, X. Artru, and R. Ramaty, *Astrophys. J.* **181**, 725 (1973).

- 14.19** Transition radiation is emitted by a relativistic particle traversing normally a uniform array of N dielectric foils, each of thickness a , separated by air gaps (effectively vacuum), each of length b . Assume that multiple reflections can be neglected for the whole stack. This requires

$$\left| \frac{n(\omega) - 1}{n(\omega) + 1} \right| \approx \frac{\omega_p^2}{4\omega^2} \ll \frac{1}{N}$$

(a) Show that if the dielectric constant of the medium varies in the z direction as $\epsilon(\omega, z) = 1 - (\omega_p^2 / \omega^2) \rho(z)$, the differential spectrum of transition radiation is given approximately by the single-interface result (14.129) times

$$\mathcal{F} = \left| \mu \int dz \rho(z) e^{i\omega z/v} \exp \left(-i \cos \theta \int^z k(z') dz' \right) \right|^2$$

where $\rho(0)=1$ by convention, $k(z)=(\omega/c)\sqrt{\epsilon(\omega, z)}$, and $\mu=\omega/v-k(0)\cos\theta$.

(b) Show that for the stack of N foils

$$\mathcal{F}=4\sin^2\Theta\frac{\sin^2[N(\Theta+\Psi)]}{\sin^2[\Theta+\Psi]}$$

where Θ is defined in Problem 14.18 and $\Psi=\nu(1+\eta)(b/4D)$. Compare G. M. Garibyan, *Zh. Eksp. Teor. Fiz.* **60**, 39 (1970) [transl. *Sov. Phys. JETP* **33**, 23 (1971)].

The practical theory of multilayered transition radiation detectors is treated in great detail by X. Artru, G. B. Yodh, and G. Mennessier, *Phys. Rev. D* **12**, 1289 (1975).

Bremsstrahlung, Method of Virtual Quanta, Radiative Beta Processes

In Chapter 14 radiation by accelerated charges was discussed in a general way, formulas were derived for frequency and angular distributions, and examples of radiation by both nonrelativistic and relativistic charged particles in external fields were treated. The present chapter is devoted to problems of emission of electromagnetic radiation by charged particles in atomic and nuclear processes.

Particles passing through matter are scattered and lose energy by collisions, as described in detail in Chapter 13. In these collisions the particles undergo acceleration; hence they emit electromagnetic radiation. The radiation emitted during atomic collisions is customarily called *bremsstrahlung* (braking radiation) because it was first observed when high-energy electrons were stopped in a thick metallic target. For nonrelativistic particles the loss of energy by radiation is negligible compared with the collisional energy loss, but for ultrarelativistic particles radiation can be the dominant mode of energy loss.

Our discussion begins with consideration of the radiation spectrum at very low frequencies where a general expression can be derived, valid quantum mechanically as well as classically. The angular distribution, the polarization, and the integrated intensity of radiation emitted in collisions of a general sort are treated before turning to the specific phenomenon of bremsstrahlung in Coulomb collisions. When appropriate, quantum-mechanical modifications are incorporated by treating the kinematics correctly (including the energy and momentum of the photon). All important quantum effects are included in this way, sometimes leading to the exact quantum-mechanical result. Relativistic effects, which can cause significant changes in the results, are discussed in detail.

The creation or annihilation of charged particles is another process in which radiation is emitted. Such processes are purely quantum mechanical in origin. There can be no attempt at a classical explanation of the basic phenomena. But given that the process does occur, we may legitimately ask about the spectrum and intensity of electromagnetic radiation accompanying it. The sudden creation

of a fast electron in nuclear beta decay, for example, can be viewed for our purposes as the violent acceleration of a charged particle initially at rest to some final velocity in a very short time interval, or, alternatively, as the sudden switching on of the charge of the moving particle in the same short interval. We discuss nuclear beta decay and orbital-electron capture in these terms in Sections 15.6 and 15.7.

In some radiative processes like bremsstrahlung it is possible to account for the major quantum-mechanical effects merely by treating the conservation of energy and momentum properly in determining the maximum and minimum effective momentum transfers. In other processes like radiative beta decay the quantum effects are more serious. Phase space modifications occur that have no classical basis. Radiation is emitted in ways that are obscure and not easily related to the acceleration of a charge. Generally, our results are limited to the region of "soft" photons, that is, photons whose energies are small compared to the total energy available. At the upper end of the frequency spectrum our semiclassical expressions can be expected to have only qualitative validity.

15.1 Radiation Emitted during Collisions

If a charged particle makes a collision, it undergoes acceleration and emits radiation. If its collision partner is also a charged particle, they both emit radiation and a coherent superposition of the radiation fields must be made. Since the amplitude of the radiation fields depends on the charge times the acceleration, the lighter particle will radiate more, provided the charges are not too dissimilar. In many applications the mass of one collision partner is much greater than the mass of the other. Then for the emission of radiation it is sufficient to treat the collision as the interaction of the lighter of the two particles with a fixed field of force. We will consider only this situation, and will leave more involved cases to the problems at the end of the chapter.

(a) Low Frequency Limit

From (14.65) and (14.66) we see that the intensity of radiation emitted by a particle of charge ze during the collision can be expressed as

$$\frac{d^2 I}{d\omega d\Omega} = \frac{z^2 e^2}{4\pi^2 c} \left| \int \frac{d}{dt} \left[\frac{\mathbf{n} \times (\mathbf{n} \times \boldsymbol{\beta})}{1 - \mathbf{n} \cdot \boldsymbol{\beta}} \right] e^{i\omega(t - \mathbf{n} \cdot \mathbf{r}(t)/c)} dt \right|^2 \quad (15.1)$$

Let us suppose that the collision has a duration τ during which significant acceleration occurs and that the collision changes the particle's velocity from an initial value $c\boldsymbol{\beta}$ to a final value $c\boldsymbol{\beta}'$. The spectrum of radiation at finite frequencies will depend on the details of the collision, but its form at low frequencies depends only on the initial and final velocities. In the limit $\omega \rightarrow 0$ the

exponential factor in (15.1) is equal to unity. Then the integrand is a perfect differential. The spectrum of radiation with polarization ϵ is therefore

$$\lim_{\omega \rightarrow 0} \frac{d^2 I}{d\omega d\Omega} = \frac{z^2 e^2}{4\pi^2 c} \left| \epsilon^* \cdot \left(\frac{\beta'}{1 - \mathbf{n} \cdot \beta'} - \frac{\beta}{1 - \mathbf{n} \cdot \beta} \right) \right|^2 \quad (15.2)$$

The result (15.2) is very general and holds quantum mechanically as well as classically. To establish the connection to the quantum-mechanical form, we first convert (15.2) into a spectrum of photons. The energy of a photon of frequency ω is $\hbar\omega$. By dividing (15.2) by $\hbar^2\omega$ we therefore obtain the differential *number* spectrum per unit *energy* interval and per unit solid angle of “soft” photons ($\hbar\omega \rightarrow 0$) of polarization ϵ :

$$\lim_{\hbar\omega \rightarrow 0} \frac{d^2 N}{d(\hbar\omega) d\Omega_\gamma} = \frac{z^2 \alpha}{4\pi^2 \hbar\omega} \left| \epsilon^* \cdot \left(\frac{\beta'}{1 - \mathbf{n} \cdot \beta'} - \frac{\beta}{1 - \mathbf{n} \cdot \beta} \right) \right|^2 \quad (15.3)$$

where $\alpha = e^2/\hbar c \approx 1/137$ is the fine structure constant if e is the proton’s charge. The subscript γ on the solid angle element serves to remind that it is the solid angle into which the photon goes. The spectrum (15.3) is to be interpreted as follows. Suppose that the collision is caused by an external potential or other interaction. Let the cross section for scattering that causes a change in velocity $c\beta \rightarrow c\beta'$ be denoted by $d\sigma/d\Omega_p$, where p stands for particle. Then the cross section for scattering and at the same time for producing a soft photon of energy $\hbar\omega$, per unit energy interval and per unit solid angle, is

$$\frac{d^3 \sigma}{d\Omega_p d(\hbar\omega) d\Omega_\gamma} = \left[\lim_{\hbar\omega \rightarrow 0} \frac{d^2 N}{d(\hbar\omega) d\Omega_\gamma} \right] \cdot \frac{d\sigma}{d\Omega_p} \quad (15.4)$$

The expression (15.3) can be made to appear more relativistically covariant by introducing the energy-momentum 4-vector of the photon, $k^\mu = (\hbar/c)(\omega, \omega\mathbf{n})$, and of the particle, $p^\mu = Mc(\gamma, \gamma\beta)$. It is also valuable to make use of the Lorentz invariant phase space d^3k/k_0 to write a manifestly invariant expression,*

$$\frac{d^3 N}{(d^3 k/k_0)} \equiv \frac{c^2}{\hbar\omega} \frac{d^2 N}{d(\hbar\omega) d\Omega_\gamma} = \frac{c^2}{\hbar(\hbar\omega)^2} \frac{d^2 I}{d\omega d\Omega_\gamma} \quad (15.5)$$

Then we find from (15.3),

$$\lim_{\hbar\omega \rightarrow 0} \frac{d^3 N}{(d^3 k/k_0)} = \frac{z^2 \alpha}{4\pi^2} \left| \frac{\epsilon^* \cdot p'}{k \cdot p'} - \frac{\epsilon^* \cdot p}{k \cdot p} \right|^2 \quad (15.6)$$

where the various scalar products are 4-vector scalar products (in the radiation gauge, $\epsilon^\mu = (0, \epsilon)$). That (15.6) emerges from a quantum-mechanical calculation can be made plausible by considering the diagrams of Fig. 15.1. The upper diagram indicates the scattering process without emission of radiation. The

* The fact that ω^{-2} times $d^2 I/d\omega d\Omega$ is a Lorentz invariant is not restricted to the limit of $\omega \rightarrow 0$. We shall find this result useful in some of our later discussions.

Fig. 15.1 Quantum-mechanical diagrams describing the scattering of a particle without photon emission (top) and with the emission of a photon (bottom).

lower three diagrams have scattering and also photon emission. Their contributions add coherently. The two diagrams on the left have the photon emitted by the external lines, that is, before or after the collision. They both involve propagators for the particle between the scattering vertex and the photon vertex of the form,

$$\frac{1}{(p \pm k)^2 - M^2} = \frac{1}{\pm 2p \cdot k}$$

In the limit $\omega \rightarrow 0$ these propagators make the contributions from these two diagrams singular and provide the $(\hbar\omega)^{-1}$ in (15.3). On the other hand, the diagram on the right has the photon emitted from the interior of the scattering vertex. Its contribution is finite as $\omega \rightarrow 0$ and so is negligible compared to the first two. The explicit calculation yields (15.4) with (15.6) in the limit that the energy and the momentum of the photon can be neglected in the kinematics. Soft photon emission occurs only from the external lines in any process and is given by the classical result.

(b) *Polarization and Spectrum Integrated over Angles*

Some limiting forms of (15.2) are of interest. If the particle moves *non-relativistically* before and after the collision, then the factors in the denominators can be put equal to unity. The radiated intensity becomes

$$\lim_{\omega \rightarrow 0} \frac{d^2 I_{NR}}{d\omega d\Omega} = \frac{z^2 e^2}{4\pi^2 c} |\epsilon^* \cdot \Delta\beta|^2 \quad (15.7)$$

where $\Delta\beta = \beta' - \beta$ is the change in velocity in the collision. This is just a dipole radiation pattern and gives, when summed over polarizations, and integrated

over angles, the total energy radiated per unit frequency interval per non-relativistic collision,

$$\lim_{\omega \rightarrow 0} \frac{dI_{NR}}{d\omega} = \frac{2z^2 e^2}{3\pi c} \cdot |\Delta\beta|^2 \quad (15.8)$$

For *relativistic* motion in which the change in velocity $\Delta\beta$ is small, (15.2) can be approximated to lowest order in $\Delta\beta$ as

$$\lim_{\omega \rightarrow 0} \frac{d^2 I}{d\omega d\Omega} \simeq \frac{z^2 e^2}{4\pi^2 c} \left| \epsilon^* \cdot \left(\frac{\Delta\beta + \mathbf{n} \times (\beta \times \Delta\beta)}{(1 - \mathbf{n} \cdot \beta)^2} \right) \right|^2 \quad (15.9)$$

where $c\beta$ is the initial (or average) velocity.

We now consider the explicit forms of the angular distribution of radiation emitted with a definite state of polarization. In collision problems it is usual that the direction of the incident particle is known and the direction of the radiation is known, but the deflected particle's direction, and consequently that of $\Delta\beta$, are not known. Consequently the plane containing the incident beam direction and the direction of the radiation is a natural one with respect to which one specifies the state of polarization of the radiation.

For simplicity we consider a small angle deflection so that $\Delta\beta$ is approximately perpendicular to the incident direction. Figure 15.2 shows the vectorial relationships. Without loss of generality \mathbf{n} , the observation direction, is chosen in the x - z plane, making an angle θ with the incident beam. The change in velocity $\Delta\beta$ lies in the x - y plane, making an angle ϕ with the x axis. Since the direction of the scattered particle is not observed, we will average over ϕ . The unit vectors ϵ_{\parallel} and ϵ_{\perp} are polarization vectors parallel and perpendicular to the plane containing β and \mathbf{n} .

A little algebra leads from (15.9) to the expressions (averaged over ϕ)

$$\left. \begin{aligned} \lim_{\omega \rightarrow 0} \frac{d^2 I_{\parallel}}{d\omega d\Omega} &= \frac{z^2 e^2}{8\pi^2 c} |\Delta\beta|^2 \frac{(\beta - \cos \theta)^2}{(1 - \beta \cos \theta)^4} \\ \lim_{\omega \rightarrow 0} \frac{d^2 I_{\perp}}{d\omega d\Omega} &= \frac{z^2 e^2}{8\pi^2 c} |\Delta\beta|^2 \frac{1}{(1 - \beta \cos \theta)^2} \end{aligned} \right\} \quad (15.10)$$

for the low-frequency limits for the two states of linear polarization. These angular distributions are valid for all types of small angle collisions. The polarization $P(\theta)$, defined as $(d^2 I_{\perp} - d^2 I_{\parallel}) / (d^2 I_{\perp} + d^2 I_{\parallel})$, vanishes at $\theta = 0$, has a maximum value of $+1$ at $\cos \theta = \beta$, and decreases monotonically for larger angles. For $\gamma \gg 1$, it has the form, $P(\theta) \simeq 2\gamma^2 \theta^2 / (1 + \gamma^4 \theta^4)$. This qualitative behavior is observed experimentally,* but departures from the $\omega \rightarrow 0$ limit are significant even for $\omega/\omega_{\max} = 0.1$.

* Recent data for electron bremsstrahlung are given by W. Lichtenberg, A. Przybylski, and M. Scheer, *Phys. Rev. A* **11**, 480 (1975).

Fig. 15.2

The sum of the two terms in (15.10) gives the angular distribution of soft radiation emitted in an arbitrary small-angle collision ($\Delta\beta$ small in magnitude and perpendicular to the incident direction). For relativistic motion the distribution is strongly peaked in the forward direction in the by now familiar fashion, with a mean angle of emission of the order of $\gamma^{-1} = Mc^2/E$. Explicitly, in the limit $\gamma \gg 1$ we have

$$\lim_{\omega \rightarrow 0} \frac{d^2 I}{d\omega d\Omega} \simeq \frac{z^2 e^2 \gamma^4 |\Delta\beta|^2}{\pi^2 c} \frac{(1 + \gamma^4 \theta^4)}{(1 + \gamma^2 \theta^2)^4} \quad (15.11)$$

The total intensity per unit frequency interval for arbitrary velocity is found by elementary integration from (15.10) to be

$$\lim_{\omega \rightarrow 0} \frac{dI}{d\omega} = \frac{2}{3\pi} \frac{z^2 e^2}{c} \gamma^2 |\Delta\beta|^2$$

For nonrelativistic motion this reduces to (15.8). Since the particle's momentum is $\mathbf{p} = \gamma Mc\beta$, this result can be written as

$$\lim_{\omega \rightarrow 0} \frac{dI}{d\omega} = \frac{2}{3\pi} \frac{z^2 e^2}{M^2 c^3} Q^2 \quad (15.12)$$

where $Q = |\mathbf{p}' - \mathbf{p}|$ is the magnitude of the momentum transfer in the collision.

Equations (15.10) and (15.12) are valid relativistically, as well as nonrelativistically, provided the change in velocity is not too large. For relativistic motion the criterion is

$$|\Delta\beta| < \frac{2}{\gamma}, \quad \text{or } Q < 2Mc \quad (15.13)$$

This can be seen from (15.2). If the two velocities β and β' have an angle $|\Delta\beta|/\beta$

between them of more than $2/\gamma$, the two terms in the amplitude will not interfere. When the direction of emission \mathbf{n} is such that one of them is large, the other is negligible. The angular distribution will be two searchlight beams, one centered along $\boldsymbol{\beta}$ and the other along $\boldsymbol{\beta}'$, each given by the absolute square of one term. The radiated intensity integrated over angles is then approximately

$$\lim_{\substack{\omega \rightarrow 0 \\ Q > 2Mc}} \frac{dI}{d\omega} \approx \frac{4z^2 e^2}{\pi c} \ln \gamma \quad (15.14)$$

For $Q > 2Mc$ the radiated intensity of soft photons is independent of Q^2 , in contrast to the linear increase with Q^2 shown by (15.12) for smaller momentum transfers. For nonrelativistic motion the momentum transfers are always less than the limit of (15.13). The intensity is therefore given by (15.12) for all momentum transfers.

(c) Qualitative Behavior at Finite Frequencies

So far we have concentrated on the very low frequency limit of (15.1). It is time to consider the qualitative behavior of the spectrum at finite frequencies. The phase factor in (15.1) controls the behavior at finite frequencies. Appreciable radiation occurs only when the phase changes relatively little during the collision. If the coordinate $\mathbf{r}(t)$ of the particle is written as

$$\mathbf{r}(t) = \mathbf{r}(0) + \int_0^t c\boldsymbol{\beta}(t') dt'$$

then, apart from a constant, the phase of the integrand in (15.1) is

$$\Phi(t) = \omega \left(t - \mathbf{n} \cdot \int_0^t \boldsymbol{\beta}(t') dt' \right)$$

If we imagine that the collision occurs during a time τ and that $\boldsymbol{\beta}$ changes relatively smoothly from its initial to final value, the criterion for appreciable radiation is

$$\omega\tau(1 - \mathbf{n} \cdot \langle \boldsymbol{\beta} \rangle) < 1 \quad (15.15)$$

where $\langle \boldsymbol{\beta} \rangle = \frac{1}{\tau} \int_0^\tau \boldsymbol{\beta}(t) dt$ is the average value of $\boldsymbol{\beta}$ during the collision. For nonrelativistic collisions this reduces to

$$\omega\tau < 1$$

At low frequencies the radiated intensity given by (15.7), but for $\omega\tau > 1$ the oscillating phase factor will cause the integral to be much smaller than when $\omega = 0$. The intensity will thus fall rapidly to zero for $\omega > 1/\tau$. For relativistic motion the situation is more complex. For small $|\Delta\boldsymbol{\beta}|$ but with $\gamma \gg 1$ the criterion

(15.15) is approximately

$$\frac{\omega\tau}{2\gamma^2}(1+\gamma^2\theta^2) < 1 \quad (15.16)$$

Now there is angular dependence. For $\omega\tau < 1$, there is significant radiation at all angles that matter. For $\omega\tau$ on the range, $1 < \omega\tau < \gamma^2$, there is appreciable radiation only out to angles of the order of θ_{\max} , where $\theta_{\max}^2 = 1/\omega\tau$. For $\omega\tau > \gamma^2$, (15.16) is not satisfied at any angle. Hence the spectrum of radiation in relativistic collisions is given approximately by (15.11) and (15.12) provided $\omega\tau \ll \gamma^2$, but modifications occur in the angular distribution as $\omega\tau$ approaches γ^2 , and the intensity at all angles decreases rapidly for $\omega \geq \gamma^2/\tau$.

15.2 Bremsstrahlung in Coulomb Collisions

The most common situation in which a continuum of radiation is emitted is in the collision of a fast particle with an atom. Because of its greater charge the nucleus is more effective at producing deflections of the incident particle than the electrons. Consequently we ignore the effects of the electrons for the present and consider the radiation emitted in the collision of a particle of charge ze , mass M , and initial velocity $c\beta$ with the Coulomb field of a fixed point charge Ze .

The elastic scattering of a charged particle by a static Coulomb field is given by the Rutherford formula (see Section 13.6):

$$\frac{d\sigma_s}{d\Omega'} = \left(\frac{2zZe^2}{pv}\right)^2 \cdot \frac{1}{(2 \sin \theta'/2)^4} \quad (15.17)$$

where θ' is the scattering angle of the particle. This cross section is correct nonrelativistically at all angles, and is true quantum-mechanically for the relativistic small-angle scattering of any particle. It is convenient to express (15.17) as a cross section for scattering per unit interval in momentum transfer Q . For elastic scattering,

$$Q^2 = 4p^2 \sin^2 \theta'/2 = 2p^2(1 - \cos \theta') \quad (15.18)$$

With $d\Omega' = d\phi' d \cos \theta' = -Q d\phi' dQ/p^2$, integration over azimuth of (15.17) gives

$$\frac{d\sigma_s}{dQ} = 8\pi \left(\frac{zZe^2}{\beta c}\right)^2 \cdot \frac{1}{Q^3} \quad (15.19)$$

In a Coulomb collision with momentum transfer Q the incident particle is accelerated and emits radiation. From the previous section we know that the angular distribution is given by (15.10), at least for small deflections, and the integrated intensity by (15.12). Since the angular distributions have already been discussed, we focus on the frequency spectrum, integrated over angles. In

analogy with (15.4) we define the *differential radiation cross section*,

$$\frac{d^2\chi}{d\omega dQ} = \frac{dI(\omega, Q)}{d\omega} \cdot \frac{d\sigma_s}{dQ}(Q) \quad (15.20)$$

where $dI(\omega, Q)/d\omega$ is the energy radiated per unit frequency interval in a collision with momentum transfer Q . The differential radiation cross section has dimensions of (area \times energy/frequency \times momentum). The cross section for photon emission per unit energy interval is obtained by dividing by $\hbar^2\omega$.

The low-frequency radiation spectrum is given by (15.12), provided Q is not too large. Inserting both (15.12) and (15.19) into (15.20) we obtain

$$\frac{d^2\chi}{d\omega dQ} = \frac{16}{3} \frac{Z^2 e^2}{c} \left(\frac{z^2 e^2}{Mc^2} \right)^2 \frac{1}{\beta^2} \cdot \frac{1}{Q} \quad (15.21)$$

This result is valid at low enough frequencies and momentum transfers so that the criteria of the previous section are satisfied. The radiation cross section integrated over momentum transfers is

$$\frac{d\chi}{d\omega} \approx \frac{16}{3} \frac{Z^2 e^2}{c} \left(\frac{z^2 e^2}{Mc^2} \right)^2 \cdot \frac{1}{\beta^2} \int_{Q_{\min}}^{Q_{\max}} \frac{dQ}{Q}$$

or

$$\frac{d\chi}{d\omega} \approx \frac{16}{3} \frac{Z^2 e^2}{c} \left(\frac{z^2 e^2}{Mc^2} \right)^2 \cdot \frac{1}{\beta^2} \ln \left(\frac{Q_{\max}}{Q_{\min}} \right) \quad (15.22)$$

In summing over momentum transfers we have incorporated the limitations on the range of validity of (15.21) by means of maximum and minimum values of Q . At any given frequency (15.21) describes approximately the differential radiation cross section for only a limited range of Q . Outside that range the cross section falls below the estimate (15.21) because one or the other of the factors in (15.20) is much smaller than (15.12) or (15.19) (or zero). This effectively limits the range of Q and leads to (15.22). Determination of the values of Q_{\max} and Q_{\min} for different physical circumstances is our next task.

(a) Classical Bremsstrahlung

In our discussion of energy loss in Chapter 13 we saw that classical considerations were applicable provided

$$\eta = \frac{zZe^2}{\hbar v} > 1$$

For particles of modest charges this means $\beta \ll 1$. In this nonrelativistic limit the maximum effective momentum transfer is not restricted by failure of (15.12). The only limit is kinematic. From (15.18) we see that

$$Q_{\max} = 2p = 2Mv \quad (15.23)$$

The lower limit on Q is determined classically by the relation between frequency and collision time that must be satisfied if there is to be significant radiation. From Sections 11.10 and 13.1 we have

$$\frac{1}{\tau} \approx \frac{v}{b}, \quad Q \approx \frac{2zZe^2}{bv}$$

so that the condition $\omega < 1/\tau$ can be written in terms of Q as

$$Q > Q_{\min}^{(c)} = \frac{2zZe^2\omega}{v^2} \quad (15.24)$$

The classical radiation cross section is therefore

$$\frac{d\chi_c}{d\omega} \approx \frac{16}{3} \frac{Z^2 e^2}{c} \left(\frac{z^2 e^2}{Mc^2} \right)^2 \cdot \frac{1}{\beta^2} \cdot \ln \left(\frac{\lambda M v^3}{z Z e^2 \omega} \right) \quad (15.25)$$

where λ is a number of order unity that takes into account our ignorance of exactly how the intensity falls to zero around $\omega\tau=1$. This cross section is meaningful only provided the argument of the logarithm is greater than unity. There is thus an upper limit $\omega_{\max}^{(c)}$ on the frequency spectrum. Phrased in terms of a photon energy it is

$$\hbar\omega_{\max}^{(c)} = \frac{2\lambda}{\eta} \left(\frac{Mv^2}{2} \right) \quad (15.26)$$

Fig. 15.3 Radiation cross section (energy \times area/unit frequency) for nonrelativistic Coulomb collisions as a function of frequency in units of the maximum frequency (E/\hbar). The classical spectrum is confined to very low frequencies. The curve marked "Bethe-Heitler" is the quantum-mechanical Born approximation result, i.e., (15.29) with $\lambda' = 1$.

Since η is large compared to unity in this classical situation, we find that the range of photon energies is limited to very soft quanta whose energies are all very small compared to the kinetic energy of the incident particle. For $\eta = 10$ the classical spectrum is shown in Fig. 15.3, with $\lambda = 2$ (chosen so that for $\eta = 1$ and $\omega = 0$ the classical and quantum-mechanical cross sections agree).

(b) *Nonrelativistic Bremsstrahlung*

In the classical limit the energy and the momentum of the photon were not considered. A posteriori such neglect was justified because (15.26) shows that the spectrum is confined to very low energy photons. But for fast, though still nonrelativistic, particles with $\eta < 1$, it is necessary to consider conservation of energy and momentum including the photon. For scattering by a fixed (or massive) center of force, the conservation requirements are

$$\begin{aligned} E &= E' + \hbar\omega \\ Q^2 &= (\mathbf{p} - \mathbf{p}' - \mathbf{k})^2 \simeq (\mathbf{p} - \mathbf{p}')^2 \end{aligned} \quad (15.27)$$

where $E = p^2/2M$ and $E' = p'^2/2M$ are the kinetic energies of the particle before and after the collision, $\hbar\omega$ and $\mathbf{k} = \hbar\omega\mathbf{n}/c$ are the energy and momentum of the photon, and Q is the momentum transferred to the scattering center, as before. The reader can verify that the neglect of the photon's momentum \mathbf{k} in the second expression for Q^2 is justified independently of the directions of the momenta provided the particles are nonrelativistic.

The maximum momentum transfer effective for radiation is again that allowed by the kinematics. Similarly the minimum effective Q is determined by the kinematics and not by the collision time.* From the second equation in (15.27) we obtain

$$\frac{Q_{\max}}{Q_{\min}} = \frac{p + p'}{p - p'} = \frac{(\sqrt{E} + \sqrt{E - \hbar\omega})^2}{\hbar\omega} \quad (15.28)$$

The second form is obtained by using conservation of energy. The radiation cross section (15.22) is therefore

$$\frac{d\chi_{\text{NR}}}{d\omega} \simeq \frac{16}{3} \frac{Z^2 e^2}{c} \left(\frac{z^2 e^2}{Mc^2} \right)^2 \cdot \frac{1}{\beta^2} \cdot \ln \left[\frac{\lambda' (\sqrt{E} + \sqrt{E - \hbar\omega})^2}{\hbar\omega} \right] \quad (15.29)$$

where again λ' is a number expected to be of order unity. Actually, with $\lambda' = 1$, (15.29) is exactly the quantum-mechanical result in the Born approximation,

* For soft photons $Q_{\min} = p - p'$ can be approximated by $Q_{\min} \simeq 2\hbar\omega/v$, while the classical expression (15.24) is $Q_{\min}^{(c)} = 2\eta\hbar\omega/v$. With $\eta < 1$, the quantum-mechanical Q_{\min} is larger than the classical and so governs the lower cutoff in Q . For more energetic photons $(p - p')$ is even larger. In relativistic collisions $Q_{\min}^{(c)}$ is γ^{-3} times its nonrelativistic value and so is much smaller than (15.33).

first calculated by Bethe and Heitler (1934). The shape of the radiation cross section as a function of frequency is shown in Fig. 15.3.

The fact that we have obtained the correct quantum-mechanical Born approximation cross section by semiclassical arguments in which the quantum aspects were only included in the kinematics can be understood from the considerations of Section 15.1, especially Fig. 15.1. In the Born approximation the scattering vertex, drawn as a blob there to indicate complicated things going on, reduces to a point vertex like the photon-particle vertices. The third diagram at the bottom is absent. Only the external lines radiate; the amplitude is given by (15.6); the exact kinematics and phase space conspire to yield (15.29).

The radiation cross section $d\chi/d\omega$ depends on the properties of the particles involved in the collision as $Z^2 z^4/M^2$, showing that the emission of radiation is most important for electrons in materials of high atomic number. The total energy lost in radiation by a particle traversing unit thickness of matter containing N fixed charges Ze (atomic nuclei) per unit volume is

$$\frac{dE_{\text{rad}}}{dx} = N \int_0^{\omega_{\text{max}}} \frac{d\chi(\omega)}{d\omega} d\omega$$

Using (15.29) for $d\chi/d\omega$ and converting to the variable of integration $x = (\hbar\omega/E)$, we can write the radiative energy loss as

$$\frac{dE_{\text{rad}}}{dx} = \frac{16}{3} NZ \left(\frac{Ze^2}{\hbar c} \right) \frac{z^4 e^4}{Mc^2} \int_0^1 \ln \left(\frac{1+\sqrt{1-x}}{\sqrt{x}} \right) dx \quad (15.30)$$

The dimensionless integral has the value unity. For comparison we write the ratio of radiative energy loss to collision energy loss (13.13) or (13.44):

$$\frac{dE_{\text{rad}}}{dE_{\text{coll}}} \approx \frac{4}{3\pi} z^2 \frac{Z}{137} \frac{m}{M} \left(\frac{v}{c} \right)^2 \frac{1}{\ln B_q} \quad (15.31)$$

For nonrelativistic particles ($v \ll c$) the radiative loss is completely negligible compared to the collision loss. The fine structure constant ($e^2/\hbar c = 1/137$) enters characteristically whenever there is emission of radiation as an additional step beyond the basic process (here the deflection of the particle in the nuclear Coulomb field). The factor m/M appears because the radiative loss involves the acceleration of the incident particle, while the collision loss involves the acceleration of an electron.

(c) Relativistic Bremsstrahlung

For relativistic particles the limits obtained from conservation of energy must be modified. The changes are of two sorts. The first is that the maximum effective Q value is no longer determined by kinematics. It was shown in Section 15.1 that (15.12) is valid only for $Q < 2Mc$. For larger Q the radiated intensity is constant in Q and given by (15.14). Because of the Q^{-3} behavior of (15.19) this

means that Q_{\max} in (15.22) is

$$Q_{\max} \approx 2Mc \quad (15.32)$$

The second modification is that the photon's *momentum* can no longer be ignored in determining the minimum momentum transfer from (15.27). The minimum clearly occurs when all three momenta are parallel:

$$Q_{\min} = p - p' - k$$

For relativistic motion of the particle both initially and finally (even though the photon may carry off appreciable energy) we can approximate $cp \approx E - M^2c^4/2E$, $cp' \approx E' - M^2c^4/2E'$, where now E and E' are the total energies. Then we obtain

$$Q_{\min} \approx \frac{M^2c^3\hbar\omega}{2EE'} \quad (15.33)$$

With (15.32) and (15.33), the radiation cross section (15.22) becomes

$$\frac{d\chi_R}{d\omega} \approx \frac{16}{3} \frac{Z^2e^2}{c} \left(\frac{z^2e^2}{Mc^2} \right)^2 \ln \left(\frac{\lambda''EE'}{Mc^2\hbar\omega} \right) \quad (15.34)$$

with the customary λ'' of order unity. This result is the same as is obtained quantum mechanically in the relativistic limit, provided the photon energy satisfies $\hbar\omega \ll E$. In the limit of $E, E' \gg Mc^2$, the quantum formula is

$$\left(\frac{d\chi_R}{d\omega} \right)_{\text{Born}} \approx \frac{16}{3} \frac{Z^2e^2}{c} \left(\frac{z^2e^2}{Mc^2} \right)^2 \left(1 - \frac{\hbar\omega}{E} + \frac{3\hbar^2\omega^2}{4E^2} \right) \left[\ln \left(\frac{2EE'}{Mc^2\hbar\omega} \right) - \frac{1}{2} \right] \quad (15.35)$$

We note in passing that since $Q_{\max} \approx 2Mc$, the small change in velocity $\Delta\beta$ always lies in the plane perpendicular to the incident direction in a relativistic collision. The angular distribution of the radiation is thus given by (15.11). The *doubly differential* radiation cross section for energy radiated per unit frequency interval and per unit solid angle for $\hbar\omega \ll E$ is then

$$\frac{d^2\chi_R}{d\omega d\Omega_\gamma} \approx \left[\frac{3}{2\pi} \gamma^2 \frac{(1+\gamma^4\theta^4)}{(1+\gamma^2\theta^2)^4} \right] \cdot \frac{d\chi_R}{d\omega} \quad (15.36)$$

where θ is the angle of emission of the photon and $d\chi_R/d\omega$ is given by (15.34). The smallness of Q_{\max}/p justifies the use of the relativistic Rutherford formula (15.19) without quantum-mechanical corrections for spin.

(d) Relativistic Bremsstrahlung by a Lorentz Transformation

It is instructive to consider the calculation of relativistic bremsstrahlung from a somewhat different point of view. Suppose that instead of using the laboratory frame where the force center is at rest we view the process as taking place in the rest frame K' of the initial particle. The emission process as it appears in the two frames is indicated schematically in Fig. 15.4. A small-angle deflection in the laboratory corresponds to nonrelativistic motion during the whole collision in

Fig. 15.4 Radiation emitted during relativistic collisions viewed from the laboratory (nucleus at rest) and the frame K' (incident particle essentially at rest).

the frame K' . The differential radiated intensity in K' is thus given by the sum of the two terms in (15.10) with $\beta = 0$:

$$\frac{d^2 I'}{d\omega' d\Omega'} = \frac{z^2 e^2}{8\pi^2 c} |\Delta \mathbf{\beta}'|^2 (1 + \cos^2 \theta')$$

Primes are used to denote quantities evaluated in the frame K' . The change in velocity can be written for nonrelativistic motion as $\Delta \mathbf{\beta}' = \Delta \mathbf{p}' / Mc$, where $\Delta \mathbf{p}'$ is the change of momentum in K' . For a small deflection in the laboratory, $\Delta \mathbf{p}'$ is perpendicular to the direction of motion and so is the same in the laboratory as in K' . Its magnitude is the momentum transfer Q . The radiated energy spectrum can therefore be written as

$$\frac{d^2 I'}{d\omega' d\Omega'} = \frac{z^2 e^2}{8\pi^2 c} \left(\frac{Q}{Mc} \right)^2 (1 + \cos^2 \theta')$$

The triply differential radiation cross section for emission of radiation per unit frequency interval, per unit solid angle, and per unit interval in momentum transfer is, in analogy to (15.20),

$$\frac{d^3 \chi'}{d\omega' d\Omega' dQ} = \frac{z^2 e^2}{8\pi^2 c} \left(\frac{Q}{Mc} \right)^2 \cdot \frac{d\sigma_s}{dQ} \cdot (1 + \cos^2 \theta') \quad (15.37)$$

This is the cross section in frame K' . No primes appear on $d\sigma_s/dQ$ or on Q^2 because to the extent that \mathbf{Q} is transverse, these quantities are obviously invariant under Lorentz transformations.*

The emission of radiation in the frame K' appears as simple dipole radiation in (15.37). To obtain the cross section in the laboratory we must make a Lorentz transformation. In Section 15.1 we saw that (15.5) is a Lorentz invariant

* Actually, we can use the manifestly invariant 4-momentum transfer whose square is given by $Q^2 = -(p_1 - p_2)^2 = (\mathbf{p}_1 - \mathbf{p}_2)^2 - (E_1 - E_2)^2/c^2$. For elastic scattering by a massive center of force, $E_1 = E_2$, and for small angles and very high energies the energy difference term can be neglected even for inelastic collisions.

quantity. With what has just been said about $d\sigma_s/dQ$, it is clear that the equation relating the differential cross sections in the two frames is

$$\frac{1}{\omega^2} \frac{d^3\chi}{d\omega d\Omega dQ} = \frac{1}{\omega'^2} \frac{d^3\chi'}{d\omega' d\Omega' dQ} \quad (15.38)$$

Thus the triply differential cross section in the laboratory is

$$\frac{d^3\chi}{d\omega d\Omega dQ} = \frac{2}{3\pi} \cdot \frac{z^2 e^2}{c} \left(\frac{Q}{Mc} \right)^2 \cdot \frac{d\sigma_s}{dQ} \cdot \left[\frac{3}{16\pi} \left(\frac{\omega}{\omega'} \right)^2 (1 + \cos^2 \theta') \right] \quad (15.39)$$

The quantities in the square brackets must, of course, be expressed in terms of (unprimed) laboratory quantities. The relativistic Doppler shift formulas are

$$\omega = \gamma\omega'(1 + \beta \cos \theta')$$

and

$$\omega' = \gamma\omega(1 - \beta \cos \theta)$$

Combining the two equations we obtain

$$\left. \begin{aligned} \frac{\omega}{\omega'} &= \frac{1}{\gamma(1 - \beta \cos \theta)} \approx \frac{2\gamma}{1 + \gamma^2 \theta^2} \\ \cos \theta' &= \frac{\cos \theta - \beta}{1 - \beta \cos \theta} \approx \frac{1 - \gamma^2 \theta^2}{1 + \gamma^2 \theta^2} \end{aligned} \right\} \quad (15.40)$$

The approximations on the right are appropriate for small angles around the incident direction in the laboratory. With these approximate forms, the square bracketed quantity in (15.39) becomes

$$\left[\frac{3}{16\pi} \left(\frac{\omega}{\omega'} \right)^2 (1 + \cos^2 \theta') \right] \approx \left[\frac{3\gamma^2}{2\pi} \frac{(1 + \gamma^4 \theta^4)}{(1 + \gamma^2 \theta^2)^4} \right]$$

which is exactly the normalized expression in (15.36). [Use of the exact forms from (15.40) leads to the sum of the two terms in (15.10).] With the Rutherford cross section (15.19), or some other collision cross section for $d\sigma_s/dQ$, if appropriate, we obtain from (15.39) the relativistic bremsstrahlung results as before.

The Doppler shift formulas illustrate an important point. Photons of energies $\hbar\omega'$ in K' , emitted at essentially any angle in that frame, appear in the laboratory within the forward cone and with energies of the order of $\hbar\omega \sim \gamma\hbar\omega'$. Thus energetic photons in the laboratory energy range $Mc^2 \ll \hbar\omega \ll \gamma Mc^2$ come from soft quanta with $\hbar\omega' \ll Mc^2$ in the rest frame of the incident particle.

15.3 Screening Effects; Relativistic Radiative Energy Loss

In the treatment of bremsstrahlung so far we have ignored the effects of the atomic electrons. As direct contributors to the acceleration of the incident

particle they can be safely ignored, since their contribution per atom is of the order of Z^{-1} times the nuclear one. But they have an indirect effect through their screening of the nuclear charge. The potential energy of the incident particle in the field of the atom can be approximated by the form (13.94). The scattering is modified from the Rutherford formula at small angles. Instead of (15.17) the scattering cross section is (13.96) with θ_{\min} given by (13.98) and (13.99). In terms of momentum transfer (15.19) is replaced by

$$\frac{d\sigma_s}{dQ} = 8\pi \left(\frac{zZe^2}{\beta c} \right)^2 \cdot \frac{Q}{(Q^2 + Q_s^2)^2} \quad (15.41)$$

where

$$Q_s = p\theta_{\min}^{(q)} = \frac{\hbar}{a} \approx \frac{Z^{1/3}}{192} mc \quad (15.42)$$

is the momentum transfer associated with the screening radius a . Note that m is the electronic mass.

The calculation of bremsstrahlung proceeds as at the beginning of Section 15.2, but with the replacement in (15.22),

$$\int_{Q_{\min}}^{Q_{\max}} \frac{dQ}{Q} \rightarrow \int_{Q_{\min}}^{Q_{\max}} \frac{Q^3 dQ}{(Q^2 + Q_s^2)^2}$$

With the assumption that Q_{\max} is very large compared with both Q_{\min} and Q_s , we find that the logarithm in (15.22) is replaced by

$$\ln \left(\frac{Q_{\max}}{Q_{\min}} \right) \rightarrow \ln \left(\frac{Q_{\max}}{\sqrt{Q_{\min}^2 + Q_s^2}} \right) - \frac{Q_s^2}{2(Q_{\min}^2 + Q_s^2)} \quad (15.43)$$

For $Q_{\min} \gg Q_s$ the effects of screening are unimportant and the results of the previous section are unaffected. But for $Q_{\min} \lesssim Q_s$, important modifications occur.

From (15.23), (15.28), and (15.32) we see that Q_{\max} can be written in all circumstances as

$$Q_{\max} \approx 2Mv \quad (15.44)$$

while from (15.28) and (15.33) we find Q_{\min} values,

$$\left. \begin{aligned} Q_{\min}^{(NR)} &= p - p' \approx \frac{2\hbar\omega}{v} \\ Q_{\min}^{(R)} &\approx \frac{\hbar\omega}{2\gamma\gamma'c} \approx \frac{\hbar\omega}{2\gamma^2c} \end{aligned} \right\} \quad (15.45)$$

The approximations on the right are applicable for soft photons. (Note that, up to factors of two in the logarithms, a universal formula for Q_{\min} for soft photons is $Q_{\min} \approx \hbar\omega/\gamma^2 v$.) Since both Q_{\min} are proportional to ω for soft photons, it is clear that there will always be a frequency below which screening effects are important. With Q_s given by (15.42), the ratio of Q_{\min} to Q_s for nonrelativistic

bremsstrahlung is

$$\frac{Q_{\min}^{(NR)}}{Q_s} \simeq \frac{384}{Z^{1/3}} \cdot \frac{\hbar\omega}{m v c} = \frac{192 M \beta}{m Z^{1/3}} \cdot \frac{\hbar\omega}{(\hbar\omega)_{\max}}$$

where $(\hbar\omega)_{\max} = Mv^2/2$. Except for extremely slow speeds the frequency at which $Q_{\min}^{(NR)} \leq Q_s$ is a tiny fraction of the maximum. For example, with 100 keV electrons on a gold target ($Z=79$), only for $\omega/\omega_{\max} < 0.04$ is screening important. For particles heavier than electrons the factor M/m makes screening totally insignificant in nonrelativistic bremsstrahlung.

For relativistic bremsstrahlung, however, screening effects can be important. The ratio of Q_{\min} to Q_s is now

$$\frac{Q_{\min}^{(R)}}{Q_s} \simeq \frac{96 \hbar\omega}{\gamma \gamma' m c^2 Z^{1/3}} = \frac{96 M}{\gamma' m Z^{1/3}} \cdot \frac{\hbar\omega}{(\hbar\omega)_{\max}}$$

where $(\hbar\omega)_{\max} = \gamma M c^2$. The presence of the factor γ' in the denominator implies that at sufficiently high energies $Q_{\min}^{(R)}$ can be less than Q_s for essentially the whole range of frequencies (if $\omega/\omega_{\max} = x$, then $\gamma' = (1-x)\gamma$). Then the screening is said to be *complete*. The incident energies for complete screening are defined as $E \gg E_s$, where the critical energy E_s is

$$E_s = \left(\frac{192 M}{m Z^{1/3}} \right) M c^2 \quad (15.46)$$

For energies large compared to E_s , Q_{\min} can be neglected compared to Q_s in (15.43) at all frequencies except the very tip of the spectrum. The radiation cross section in the complete screening limit is thus the constant value,

$$\frac{d\chi}{d\omega} \simeq \frac{16}{3} \frac{Z^2 e^2}{c} \left(\frac{z^2 e^2}{M c^2} \right)^2 \ln \left(\frac{233 M}{m Z^{1/3}} \right) \quad (15.47)$$

The numerical coefficient in the logarithm is subject to some uncertainty, of course. Bethe and Heitler found a result with 183 instead of 233 in the logarithm and with the polynomial $(1 - \hbar\omega/E + 3\hbar^2\omega^2/4E^2)$ of (15.35) multiplying it.

For electrons, $E_s \approx 42$ MeV in aluminum ($Z=13$) and 23 MeV in lead ($Z=82$). The corresponding values for mu mesons are 2×10^6 MeV and 10^6 MeV. Because of the factor M/m , screening is important only for electrons. When $E > E_s$, the radiation cross section is given by the constant value (15.47) for all frequencies. Figure 15.5 shows the radiation cross section (15.47) in the limit of complete screening, as well as the corresponding Bethe-Heitler result. Their proper quantum treatment involves the slowly varying polynomial which changes from unity at $\omega = 0$ to 0.75 at $\omega = \omega_{\max}$. For cosmic-ray electrons and for electrons from most high-energy electron accelerators, the bremsstrahlung is in the complete screening limit. Thus the photon spectrum shows a typical $(\hbar\omega)^{-1}$ behavior.

The radiative energy loss was considered in the nonrelativistic limit in Section

Fig. 15.5 Radiation cross section in the complete screening limit. The constant value is the semi-classical result. The curve marked “Bethe-Heitler” is the quantum-mechanical Born approximation.

15.2(b) and was found to be negligible compared to the energy loss by collisions. For ultrarelativistic particles, especially electrons, this is no longer true. The radiative energy loss is given approximately in the limit $\gamma \gg 1$ by

$$\frac{dE_{\text{rad}}}{dx} \approx \frac{16}{3} N \frac{Z^2 e^2}{c} \left(\frac{z^2 e^2}{Mc^2} \right)^2 \int_0^{\gamma Mc^2/\hbar} \ln \left(\frac{Q_{\text{max}}}{\sqrt{Q_{\text{min}}^2 + Q_s^2}} \right) d\omega$$

For negligible screening we find approximately

$$\frac{dE_{\text{rad}}}{dx} \approx \frac{16}{3} N \frac{Z^2 e^2}{\hbar c} \left(\frac{z^2 e^2}{Mc^2} \right)^2 \ln(\lambda \gamma) \gamma Mc^2$$

For higher energies where complete screening occurs this is modified to

$$\frac{dE_{\text{rad}}}{dx} \approx \left[\frac{16}{3} N \frac{Z^2 e^2}{\hbar c} \left(\frac{z^2 e^2}{Mc^2} \right)^2 \ln \left(\frac{233M}{Z^{1/3}m} \right) \right] \gamma Mc^2 \quad (15.48)$$

showing that eventually the radiative loss is proportional to the particle's energy.

The comparison of radiative loss to collision loss now becomes

$$\frac{dE_{\text{rad}}}{dE_{\text{coll}}} \approx \frac{4}{3\pi} \left(\frac{Zz^2}{137} \right) \frac{m}{M} \frac{\ln \left(\frac{233M}{Z^{1/3}m} \right)}{\ln B_q} \gamma$$

The value of γ for which this ratio is unity depends on the particle and on Z . For electrons it is $\gamma \sim 200$ for air and $\gamma \sim 20$ for lead. At higher energies, the radiative energy loss is larger than the collision loss and for ultrarelativistic particles is the dominant loss mechanism.

At energies where the radiative energy loss is dominant the complete screening result (15.48) holds. Then it is useful to introduce a unit of length X_0 , called the *radiation length*, which is the distance a particle travels while its energy falls to e^{-1} of its initial value. By conservation of energy, we may rewrite (15.48)

as

$$\frac{dE}{dx} = -\frac{E}{X_0}$$

with solution,

$$E(x) = E_0 e^{-x/X_0}$$

where the radiation length X_0 is

$$X_0 = \left[\frac{16}{3} N \frac{Z^2 e^2}{\hbar c} \left(\frac{z^2 e^2}{Mc^2} \right)^2 \ln \left(\frac{233M}{Z^{1/3}m} \right) \right]^{-1} \quad (15.49)$$

For electrons, some representative values of X_0 are 32 gm/cm² (270 meters) in air at N.T.P., 19 gm/cm² (7.2 cm) in aluminum, and 4.4 gm/cm² (0.39 cm) in lead.* In studying the passage of cosmic-ray or man-made high-energy particles through matter, the radiation length X_0 is a convenient unit to employ, since not only the radiative energy loss is governed by it, but also the production of negaton-positon pairs by the radiated photons, and so the whole development of the electronic cascade shower.

15.4 Weizsäcker-Williams Method of Virtual Quanta

The emission of bremsstrahlung and other processes involving the electromagnetic interaction of relativistic particles can be viewed in a way that is very helpful in providing physical insight into the processes. This point of view is called the *method of virtual quanta*. It exploits the similarity between the fields of a rapidly moving charged particle and the fields of a pulse of radiation (see Section 11.10) and correlates the effects of the collision of the relativistic charged particle with some system with the corresponding effects produced by the interaction of radiation (the virtual quanta) with the same system. The method was developed independently by C. F. Weizsäcker and E. J. Williams in 1934. Ten years earlier Enrico Fermi had used essentially the same idea to relate the energy loss by ionization to the absorption of X-rays by atoms (see Problem 15.10).

In any given collision we define an "incident particle" and a "struck system." The perturbing fields of the incident particle are replaced by an equivalent pulse of radiation which is analyzed into a frequency spectrum of virtual quanta. Then the effects of the quanta (either scattering or absorption) on the struck system are calculated. In this way the charged-particle interaction is correlated with the photon interaction. The table lists a few typical correspondences and specifies

* These numerical values differ by ~20–30 per cent from those given by Rossi, p. 55, because he uses a more accurate coefficient of 4 instead of $\frac{16}{3}$ and $Z(Z+1)$ instead of Z^2 in (15.49).

Correspondences between charged particle interactions and photon interactions

Particle Process	Incident Particle	Struck System	Radiative Process	b_{\min}
Bremsstrahlung in electron (light particle)-nucleus collision	Nucleus	Electron (light particle)	Scattering of virtual photons of nuclear Coulomb field by the electron (light particle)	$\hbar/2Mv$
Collisional ionization of atoms (in distant collisions)	Incident particle	Atom	Photoejection of atomic electrons by virtual quanta	a
Electron disintegration of nuclei	Electron	Nucleus	Photodisintegration of nuclei by virtual quanta	Larger of $\hbar/\gamma m v$ and R
Production of pions in electron-nuclear collisions	Electron	Nucleus	Photoproduction of pions by virtual quanta interactions with nucleus	

the incident particle and struck system. From the table we see that the struck system is not always the target in the laboratory. For bremsstrahlung the struck system is the lighter of the two collision partners, since its radiation scattering power is greater. For bremsstrahlung in electron-electron collision it is necessary from symmetry to take the sum of two contributions where each electron in turn is the struck system at rest initially in some reference frame.

The chief assumption in the method of virtual quanta is that the effects of the various frequency components of equivalent radiation add incoherently. This will be true provided the perturbing effect of the fields is small, and is consistent with our assumption in Section 15.2(d) that the motion of the particle in the frame K' was nonrelativistic throughout the collision.

It is convenient in the discussion of the Weizsäcker-Williams method to use the language of impact parameters rather than momentum transfers in order to make use of results on the Fourier transforms of fields obtained in previous chapters. The connection between the two approaches is via the uncertainty principle relation,

$$b \sim \frac{\hbar}{Q}$$

With the expression (15.44) for Q_{\max} in bremsstrahlung, we see that the minimum impact parameter effective in producing radiation is

$$b_{\min} \approx \frac{\hbar}{Q_{\max}} \approx \frac{\hbar}{2Mv} \quad (15.50)$$

as listed in the table above. The maximum impact parameters corresponding to

the Q_{\min} values of (15.45) do not need to be itemized. The spectrum of virtual quanta automatically incorporates the cutoff equivalent to Q_{\min} .

The spectrum of equivalent radiation for an incident particle of charge q , velocity $v \approx c$, passing a struck system S at impact parameter b , can be found from the fields of Section 11.10:

$$E_2(t) = q \frac{\gamma b}{(b^2 + \gamma^2 v^2 t^2)^{3/2}}$$

$$B_3(t) = \beta E_2(t)$$

$$E_1(t) = -q \frac{\gamma vt}{(b^2 + \gamma^2 v^2 t^2)^{3/2}}$$

For $\beta \approx 1$ the fields $E_2(t)$ and $B_3(t)$ are completely equivalent to a pulse of plane polarized radiation P_1 incident on S in the x_1 direction, as shown in Fig. 15.6. There is no magnetic field to accompany $E_1(t)$ and so form a proper pulse of radiation P_2 incident along the x_2 direction, as shown. Nevertheless, if the motion of the charged particles in S is nonrelativistic in this coordinate frame, we can add the necessary magnetic field to create the pulse P_2 without affecting the physical problem because the particles in S respond only to electric forces. Even if the particles in S are influenced by magnetic forces, the additional magnetic field implied by replacing $E_1(t)$ by the radiation pulse P_2 is not important, since the pulse P_2 will be seen to be of minor importance anyway.

From the discussion Section 14.5, especially equations (14.51), (14.52), and (14.60), it is evident that the equivalent pulse P_1 has a frequency spectrum (energy per unit area per unit frequency interval) $dI_1(\omega, b)/d\omega$ given by

$$\frac{dI_1}{d\omega}(\omega, b) = \frac{c}{2\pi} |E_2(\omega)|^2 \quad (15.51a)$$

where $E_2(\omega)$ is the Fourier transform (14.54) of $E_2(t)$. Similarly the pulse P_2 has

Fig. 15.6 Relativistic charged particle passing the struck system S and the equivalent pulses of radiation.

the frequency spectrum,

$$\frac{dI_2}{d\omega}(\omega, b) = \frac{c}{2\pi} |E_1(\omega)|^2 \quad (15.51b)$$

The Fourier integrals have already been calculated in Chapter 13 and are given by (13.29) and (13.30). The two frequency spectra are

$$\left. \begin{aligned} \frac{dI_1(\omega, b)}{d\omega} \\ \frac{dI_2(\omega, b)}{d\omega} \end{aligned} \right\} = \frac{1}{\pi^2} \frac{q^2}{c} \left(\frac{c}{v}\right)^2 \frac{1}{b^2} \left\{ \begin{aligned} &\left(\frac{\omega b}{\gamma v}\right)^2 K_1^2\left(\frac{\omega b}{\gamma v}\right) \\ &\frac{1}{\gamma^2} \left(\frac{\omega b}{\gamma v}\right)^2 K_0^2\left(\frac{\omega b}{\gamma v}\right) \end{aligned} \right\} \quad (15.52)$$

We note that the intensity of the pulse P_2 involves a factor γ^{-2} and so is of little importance for ultrarelativistic particles. The shapes of these spectra are shown qualitatively in Fig. 15.7. The behavior is easily understood if one recalls that the fields of pulse P_1 are bell-shaped in time with a width $\Delta t \sim b/\gamma v$. Thus the frequency spectrum will contain all frequencies up to a maximum of order $\omega_{\max} \sim 1/\Delta t$. On the other hand, the fields of pulse P_2 are similar to one cycle of a sine wave of frequency $\omega \sim \gamma v/b$. Consequently its spectrum will contain only a modest range of frequencies centered around $\gamma v/b$.

In collision problems we must sum the frequency spectra (15.52) over the various possible impact parameters. This gives the energy per unit frequency interval present in the equivalent radiation field. As always in such problems we must specify a minimum impact parameter b_{\min} . The method of virtual quanta will be useful only if b_{\min} can be so chosen that for impact parameters greater than b_{\min} the effects of the incident particle's fields can be represented accurately by the effects of equivalent pulses of radiation, while for small impact parameters the effects of the particle's fields can be neglected or taken into account by other means. Setting aside for the moment how we choose the proper value of b_{\min} in general [(15.50) is valid for bremsstrahlung], we can write down the frequency spectrum integrated over possible impact parameters,

$$\frac{dI}{d\omega}(\omega) = 2\pi \int_{b_{\min}}^{\infty} \left[\frac{dI_1}{d\omega}(\omega, b) + \frac{dI_2}{d\omega}(\omega, b) \right] b db \quad (15.53)$$

Fig. 15.7 Frequency spectra of the two equivalent pulses of radiation.

where we have combined the contributions of pulses P_1 and P_2 . This integral has already been done in Section 13.3, equation (13.35). The result is

$$\frac{dI}{d\omega}(\omega) = \frac{2}{\pi} \frac{q^2}{c} \left(\frac{c}{v}\right)^2 \left\{ x K_0(x) K_1(x) - \frac{v^2}{2c^2} x^2 [K_1^2(x) - K_0^2(x)] \right\} \quad (15.54)$$

where

$$x = \frac{\omega b_{\min}}{\gamma v} \quad (15.55)$$

For low frequencies ($\omega \ll \gamma v/b_{\min}$) the energy per unit frequency interval reduces to

$$\frac{dI}{d\omega}(\omega) \approx \frac{2}{\pi} \frac{q^2}{c} \left(\frac{c}{v}\right)^2 \left[\ln \left(\frac{1.123 \gamma v}{\omega b_{\min}} \right) - \frac{v^2}{2c^2} \right] \quad (15.56)$$

whereas for high frequencies ($\omega \gg \gamma v/b_{\min}$) the spectrum falls off exponentially as

$$\frac{dI}{d\omega}(\omega) \approx \frac{q^2}{c} \left(\frac{c}{v}\right)^2 \left(1 - \frac{v^2}{2c^2}\right) e^{-(2\omega b_{\min}/\gamma v)} \quad (15.57)$$

Figure 15.8 shows an accurate plot of $I(\omega)$ (15.54) for $v \approx c$, as well as the low-frequency approximation (15.56). We see that the energy spectrum consists

Fig. 15.8 Frequency spectrum of virtual quanta for a relativistic particle, with the energy per unit frequency $dI(\omega)/d\omega$ in units of $q^2/\pi c$ and the frequency in units of $\gamma v/b_{\min}$. The number of virtual quanta per unit energy interval is obtained by dividing by $\hbar^2 \omega$.

predominantly of low-frequency quanta with a tail extending up to frequencies of the order of $2\gamma v/b_{\min}$.

The number spectrum of virtual quanta $N(\hbar\omega)$ is obtained by using the relation,

$$\frac{dI}{d\omega}(\omega) d\omega = \hbar\omega N(\hbar\omega) d(\hbar\omega) \quad (15.58)$$

Thus the number of virtual quanta per unit energy interval in the low-frequency limit is

$$N(\hbar\omega) \approx \frac{2}{\pi} \left(\frac{q^2}{\hbar c} \right) \left(\frac{c}{v} \right)^2 \frac{1}{\hbar\omega} \left[\ln \left(\frac{1.123\gamma v}{\omega b_{\min}} \right) - \frac{v^2}{2c^2} \right] \quad (15.59)$$

The choice of minimum impact parameter b_{\min} must be considered. In bremsstrahlung, $b_{\min} = \hbar/2Mv$, where M is the mass of the lighter particle, as already discussed. For collisional ionization of atoms, $b_{\min} \approx a$, the atomic radius, closer impacts being treated as collisions between the incident particle and free electrons. In electron disintegration of nuclei or electron production of mesons from nuclei, the wave nature of the particle whose fields provide the virtual quanta sets the effective minimum impact parameter. In these circumstances, $b_{\min} = \hbar/\gamma Mv$ or $b_{\min} = R$, the nuclear radius, whichever is larger. The values are summarized in the table on p. 720.

15.5 Bremsstrahlung as the Scattering of Virtual Quanta

The emission of bremsstrahlung in a collision between an incident relativistic particle of charge ze and mass M and an atomic nucleus of charge Ze can be viewed as the scattering of the virtual quanta in the nuclear Coulomb field by the incident particle in the coordinate system K' , where the incident particle is at rest. The spectrum of virtual quanta $dI'(\omega')/d\omega'$ is given by (15.54) with $q = Ze$. The minimum impact parameter is $\hbar/2Mv$, so that the frequency spectrum extends up to $\omega' \sim \gamma Mc^2/\hbar$.

The virtual quanta are scattered by the incident particle (the struck system in K') according to the Thomson cross section (14.103) at low frequencies. Thus, in the frame K' and for frequencies small compared to Mc^2/\hbar , the differential radiation cross section is approximately

$$\frac{d\chi'}{d\omega' d\Omega'} \approx \left(\frac{z^2 e^2}{Mc^2} \right)^2 \cdot \frac{1}{2} (1 + \cos^2 \theta') \cdot \frac{dI'}{d\omega'}$$

Since the spectrum of virtual quanta extends up to $\gamma Mc^2/\hbar$, the approximation (15.56) can be used for $dI'(\omega')/d\omega'$ in the region $\omega' \ll Mc^2/\hbar$. Thus the radiation cross section in K' becomes

$$\frac{d\chi'}{d\omega' d\Omega'} \approx \frac{1}{\pi} \frac{Z^2 e^2}{c} \left(\frac{z^2 e^2}{Mc^2} \right)^2 (1 + \cos^2 \theta') \cdot \ln \left(\frac{\lambda \gamma Mc^2}{\hbar \omega'} \right) \quad (15.60)$$

The cross section in the laboratory can be obtained in the same fashion as in Section 15.2(d). Using (15.38) and the Doppler formulas (15.40) we find

$$\frac{d\chi}{d\omega d\Omega} \approx \frac{16}{3} \frac{Z^2 e^2}{c} \left(\frac{z^2 e^2}{Mc^2} \right)^2 \ln \left(\frac{2\lambda \gamma^2 Mc^2}{\hbar \omega (1 + \gamma^2 \theta^2)} \right) \cdot \left[\frac{3\gamma^2 (1 + \gamma^4 \theta^4)}{2\pi (1 + \gamma^2 \theta^2)^4} \right] \quad (15.61)$$

This is essentially the same cross section as (15.36). Upon integration over angles of emission it yields an expression equal to the soft-photon limit of (15.34).

Equations (15.60) and (15.61) are based on the Thomson scattering cross section and so are restricted to $\omega' < Mc^2/\hbar$ in the rest frame K' . Of course, as has already been observed in Section 15.2(d), such soft photons transform into energetic photons in the laboratory. But the spectrum of virtual quanta contains frequencies up to $\omega' \approx \gamma Mc^2/\hbar$. For such frequencies the scattering of radiation is not given by the Thomson cross section, but rather by (14.105) for spinless struck particles or the Klein-Nishina formula for particles of spin $\frac{1}{2}$. The angular distribution of scattering of such photons is altered from the dipole form of (15.60), as is shown in Fig. 14.13. More important is the fact that the total cross section for scattering decreases rapidly for frequencies larger than Mc^2/\hbar , as can be seen from (14.106). This shows that in the frame K' the bremsstrahlung quanta are confined to a frequency range $0 < \omega' \leq Mc^2/\hbar$, even though the spectrum of virtual quanta in the nuclear Coulomb field extends to much higher frequencies. The restricted spectrum in K' is required physically by conservation of energy, since in the laboratory system where $\omega \approx \gamma \omega'$ the frequency spectrum is limited to $0 < \omega < (\gamma Mc^2/\hbar)$. A detailed treatment using the angular distribution of scattering from the Klein-Nishina formula yields a bremsstrahlung cross section in complete agreement with the Bethe-Heitler formulas (Weizsäcker, 1934).

The effects of screening on the bremsstrahlung spectrum can be discussed in terms of the Weizsäcker-Williams method. For a screened Coulomb potential the spectrum of virtual quanta is modified from (15.56). The argument of the logarithm is changed to a constant, as was discussed in Section 15.3.

Further applications of the method of virtual quanta to such problems as collisional ionization of atoms and electron distintegration of nuclei are deferred to the problems at the end of the chapter.

15.6 Radiation Emitted During Beta Decay

In the process of beta decay an unstable nucleus with atomic number Z transforms spontaneously into another nucleus of atomic number $(Z \pm 1)$ while emitting an electron ($\mp e$) and a neutrino. The process is written symbolically as

$$Z \rightarrow (Z \pm 1) + e^\mp + \nu \quad (15.62)$$

The energy released in the decay is shared almost entirely by the electron and the neutrino, with the recoiling nucleus getting a completely negligible share because of its very large mass. Even without knowledge of why or how beta decay takes place, we can anticipate that the sudden creation of a rapidly moving charged particle will be accompanied by the emission of radiation. As mentioned in the introduction, either we can think of the electron initially at rest and being accelerated violently during a short time interval to its final velocity, or we can imagine that its charge is suddenly turned on in the same short time interval. The heavy nucleus receives a negligible acceleration and so does not contribute to the radiation.

For purposes of calculation we can assume that at $t=0$ an electron is created at the origin with a constant velocity $\mathbf{v}=c\boldsymbol{\beta}$. Then from (15.1) or (15.2) the intensity distribution of radiation is given by

$$\frac{dI}{d\omega d\Omega} = \frac{e^2}{4\pi^2 c} \left| \frac{\boldsymbol{\epsilon}^* \cdot \boldsymbol{\beta}}{1 - \mathbf{n} \cdot \boldsymbol{\beta}} \right|^2 \quad (15.63)$$

This is the low-frequency limit of the energy spectrum. The intensity will decrease from this value at frequencies that violate the condition (15.15). Although it is difficult to be precise about the value of $\langle \boldsymbol{\beta} \rangle$ that appears there, if the formation process is imagined to involve a velocity versus time curve, such as is sketched in Fig. 15.9, the value of $\langle \boldsymbol{\beta} \rangle$ should not be greater than $\frac{1}{2}$. In that case, the criterion (15.15) is equivalent to $\omega\tau < 1$. The formation time τ can be estimated from the uncertainty principle to be

$$\tau \sim \frac{\hbar}{\Delta E} \sim \frac{\hbar}{E} \quad (15.64)$$

since in the act of beta decay an electron of total energy E is suddenly created. This estimate of τ implies the frequencies for appreciable radiation are limited to $\omega < E/\hbar$. This is just the limit imposed by conservation of energy. The radiation is seen from (15.63) to be linearly polarized in the plane containing the velocity vector of the electron and the direction of observation. The differential

Fig. 15.9

distribution in spherical coordinates is

$$\frac{d^2 I}{d\omega d\Omega} = \frac{e^2}{4\pi^2 c} \beta^2 \frac{\sin^2 \theta}{(1 - \beta \cos \theta)^2} \quad (15.65)$$

while the total intensity per unit frequency interval is

$$\frac{dI}{d\omega}(\omega) = \frac{e^2}{\pi c} \left[\frac{1}{\beta} \ln \left(\frac{1+\beta}{1-\beta} \right) - 2 \right] \quad (15.66)$$

For $\beta \ll 1$, (15.66) reduces to $dI/d\omega \approx 2e^2\beta^2/3\pi c$, showing that for low-energy beta particles the radiated intensity is negligible.

The intensity distribution (15.66) is a typical bremsstrahlung spectrum with number of photons per unit energy range given by

$$N(\hbar\omega) = \frac{e^2}{\pi \hbar c} \left(\frac{1}{\hbar\omega} \right) \left[\frac{1}{\beta} \ln \left(\frac{1+\beta}{1-\beta} \right) - 2 \right] \quad (15.67)$$

It sometimes bears the name *inner bremsstrahlung* to distinguish it from bremsstrahlung emitted by the same beta particle in passing through matter.

The total energy radiated is approximately

$$E_{\text{rad}} = \int_0^{\omega_{\text{max}}} \frac{dI}{d\omega}(\omega) d\omega \approx \frac{e^2}{\pi \hbar c} \left[\frac{1}{\beta} \ln \left(\frac{1+\beta}{1-\beta} \right) - 2 \right] E \quad (15.68)$$

For very fast beta particles, the ratio of energy going into radiation to the particle energy is

$$\frac{E_{\text{rad}}}{E} \approx \frac{2}{\pi} \frac{e^2}{\hbar c} \left[\ln \left(\frac{2E}{mc^2} \right) - 1 \right] \quad (15.69)$$

This shows that the radiated energy is a very small fraction of the total energy released in beta decay, even for the most energetic beta processes ($E_{\text{max}} \sim 30mc^2$). Nevertheless, the radiation can be observed, and provides useful information for nuclear physicists.

In the actual beta process the energy release is shared by the electron and the neutrino so that the electron has a whole spectrum of energies up to some maximum. Then the radiation spectrum (15.66) must be averaged over the energy distribution of the beta particles. Furthermore, a quantum-mechanical treatment leads to modifications near the upper end of the photon spectrum. These are important details for quantitative comparison with experiment. But the origins of the radiation and its semiquantitative description are given adequately by our classical calculation.

15.7 Radiation Emitted During Orbital-Electron Capture—Disappearance of Charge and Magnetic Moment

In beta emission the sudden creation of a fast electron gives rise to radiation. In orbital-electron capture the sudden disappearance of an electron does likewise.

Fig. 15.10

Orbital-electron capture is the process whereby an orbital electron around an unstable nucleus of atomic number Z is captured by the nucleus, transforming it into another nucleus with atomic number $(Z-1)$, with the simultaneous emission of a neutrino which carries off the excess energy. The process can be written symbolically as

Since a virtually undetectable neutrino carries away the decay energy if there is no radiation, the spectrum of photons accompanying orbital electron capture is of great importance in yielding information about the energy release.

As a simplified model we consider an electron moving in a circular atomic orbit of radius a with a constant angular velocity ω_0 . The orbit lies in the x - y plane, as shown in Fig. 15.10, with the nucleus at the center. The observation direction \mathbf{n} is defined by the polar angle θ and lies in the x - z plane. The velocity of the electron is

$$\mathbf{v}(t) = -\epsilon_1 \omega_0 a \sin(\omega_0 t + \alpha) + \epsilon_2 \omega_0 a \cos(\omega_0 t + \alpha) \quad (15.71)$$

where α is an arbitrary phase angle. If the electron vanishes at $t=0$, the frequency spectrum of emitted radiation (14.67) is approximately*

$$\frac{d^2 I}{d\omega d\Omega} = \frac{e^2 \omega^2}{4\pi^2 c^3} \left| \int_{-\infty}^0 \mathbf{n} \times [\mathbf{n} \times \mathbf{v}(t)] e^{i\omega t} dt \right|^2 \quad (15.72)$$

where we have assumed that $(\omega a/c) \ll 1$ (dipole approximation) and put the retardation factor equal to unity. The integral in (15.72) can be written

$$\int_{-\infty}^0 dt = -\omega_0 a (\epsilon_{\perp} I_1 + \epsilon_{\parallel} \cos \theta I_2) \quad (15.73)$$

* To conform to the admonition below (14.67) we should multiply the velocity (15.71) by a factor such as $(1 - e^{t/\tau})\theta(-t)$ in order to bring the velocity to zero continuously in a short time τ near $t=0$. The reader may verify that in the limit $\omega_0 \tau \ll 1$ and $\omega \tau \ll 1$ the results given below emerge.

where

$$\left. \begin{aligned} I_1 &= \int_{-\infty}^0 \cos(\omega_0 t + \alpha) e^{i\omega t} dt \\ I_2 &= \int_{-\infty}^0 \sin(\omega_0 t + \alpha) e^{i\omega t} dt \end{aligned} \right\} \quad (15.74)$$

and ϵ_{\perp} , ϵ_{\parallel} are unit polarization vectors perpendicular and parallel to the plane containing \mathbf{n} and the z axis. The integrals are elementary and lead to an intensity distribution,

$$\frac{d^2 I}{d\omega d\Omega} = \frac{e^2 \omega^2}{4\pi^2 c^3} \frac{\omega_0^2 a^2}{(\omega^2 - \omega_0^2)^2} [(\omega^2 \cos^2 \alpha + \omega_0^2 \sin^2 \alpha) + \cos^2 \theta (\omega^2 \sin^2 \alpha + \omega_0^2 \cos^2 \alpha)] \quad (15.75)$$

Since the electron can be captured from any position around the orbit, we average over the phase angle α . Then the intensity distribution is

$$\frac{d^2 I}{d\omega d\Omega} = \frac{e^2}{4\pi^2 c} \left(\frac{\omega_0 a}{c} \right)^2 \frac{\omega^2 (\omega^2 + \omega_0^2)}{(\omega^2 - \omega_0^2)^2} \cdot \frac{1}{2} (1 + \cos^2 \theta) \quad (15.76)$$

The total energy radiated per unit frequency interval is

$$\frac{dI(\omega)}{d\omega} = \frac{2}{3\pi} \frac{e^2}{c} \left(\frac{\omega_0 a}{c} \right)^2 \left[\frac{\omega^2 (\omega_0^2 + \omega^2)}{(\omega^2 - \omega_0^2)^2} \right] \quad (15.77)$$

while the number of photons per unit energy interval is

$$N(\hbar\omega) = \frac{2}{3\pi} \left(\frac{e^2}{\hbar c} \right) \left(\frac{\omega_0 a}{c} \right)^2 \left[\frac{\omega^2 (\omega_0^2 + \omega^2)}{(\omega^2 - \omega_0^2)^2} \right] \frac{1}{\hbar\omega} \quad (15.78)$$

For $\omega \gg \omega_0$ the square-bracketed quantity approaches unity. Then the spectrum is a typical bremsstrahlung spectrum. But for $\omega \approx \omega_0$ the intensity is very large (infinite in our approximation). The behavior of the photon spectrum is shown in Fig. 15.11. The singularity at $\omega = \omega_0$ may seem alarming, but it is really quite natural and expected. If the electron were to keep orbiting forever, the radiation spectrum would be a sharp line at $\omega = \omega_0$. The sudden termination of the periodic motion produces a broadening of the spectrum in the neighborhood of the characteristic frequency.

Quantum mechanically the radiation arises when an $l=1$ electron (mainly from the $2p$ orbit) makes a virtual radiative transition to an $l=0$ state, from which it can be absorbed by the nucleus. Thus the frequency ω_0 must be identified with the frequency of the characteristic $2p \rightarrow 1s$ X-ray, $\hbar\omega_0 \approx (3Z^2 e^2 / 8a_0)$. Similarly the orbit radius is actually a transitional dipole moment. With the estimate $a \approx a_0/Z$, where a_0 is the Bohr radius, the photon spectrum (15.78) is

$$N(\hbar\omega) \approx \frac{3}{32\pi} Z^2 \left(\frac{e^2}{\hbar c} \right)^3 \frac{1}{\hbar\omega} \left[\frac{\omega^2 (\omega^2 + \omega_0^2)}{(\omega^2 - \omega_0^2)^2} \right] \quad (15.79)$$

Fig. 15.11 Spectrum of photons emitted in orbital electron capture because of disappearance of the charge of the electron.

The essential characteristics of this spectrum are its strong peaking at the X-ray energy and its dependence on atomic number as Z^2 .

So far we have considered the radiation which accompanies the disappearance of the charge of an orbital electron in the electron-capture process. An electron possesses a magnetic moment as well as a charge. The disappearance of the magnetic moment also gives rise to radiation, but with a spectrum of quite different character. The intensity distribution in angle and frequency for a point magnetic moment in motion is given by (14.74). The electronic magnetic moment can be treated as a constant vector in space until its disappearance at $t=0$. Then, in the dipole approximation and with $\beta \ll 1$, the appropriate intensity distribution is

$$\frac{d^2 I}{d\omega d\Omega} = \frac{\omega^4}{4\pi^2 c^3} \left| \int_{-\infty}^0 \mathbf{n} \times \boldsymbol{\mu} e^{i\omega t} dt \right|^2 \quad (15.80)$$

This gives

$$\frac{d^2 I}{d\omega d\Omega} = \frac{\omega^2}{4\pi^2 c^3} \mu^2 \sin^2 \Theta \quad (15.81)$$

where Θ is the angle between $\boldsymbol{\mu}$ and the observation direction \mathbf{n} .

In a semiclassical sense the electronic magnetic moment can be thought of as having a magnitude $\mu = \sqrt{3}(e\hbar/2mc)$, but being observed only through its projection $\mu_z = \pm(e\hbar/2mc)$ on an arbitrary axis. The moment can be thought of as precessing around the axis at an angle $\alpha = \tan^{-1} \sqrt{2}$, so that on the average only the component of the moment along the axis survives. It is easy to show that on averaging over this precession $\sin^2 \Theta$ in (15.81) becomes equal to its average value of $\frac{2}{3}$, independent of observation direction. Thus the angular and frequency

spectrum becomes

$$\frac{d^2 I}{d\omega d\Omega} = \frac{e^2}{8\pi^2 c} \left(\frac{\hbar\omega}{mc^2} \right)^2 \quad (15.82)$$

The total energy radiated per unit frequency interval is

$$\frac{dI}{d\omega} = \frac{e^2}{2\pi c} \left(\frac{\hbar\omega}{mc^2} \right)^2 \quad (15.83)$$

while the corresponding number of photons per unit energy interval is

$$N(\hbar\omega) = \frac{e^2}{2\pi\hbar c} \frac{\hbar\omega}{(mc^2)^2} \quad (15.84)$$

These spectra are very different in their frequency dependence from a bremsstrahlung spectrum. They increase with increasing frequency, apparently without limit. Of course, we have been forewarned that our classical results are valid only in the low-frequency limit. We can imagine that some sort of uncertainty-principle argument such as was used in Section 15.6 for radiative beta decay holds here and that conservation of energy, at least, is guaranteed. Actually, modifications arise because a neutrino is always emitted in the electron-capture process. The probability of emission of the neutrino can be shown to depend on the square of its energy E_ν . When no photon is emitted, the neutrino has the full decay energy $E_\nu = E_0$. But when a photon of energy $\hbar\omega$ accompanies it, the neutrino's energy is reduced to $E'_\nu = E_0 - \hbar\omega$. Then the probability of neutrino emission is reduced by a factor,

$$\left(\frac{E'_\nu}{E_\nu} \right)^2 = \left(1 - \frac{\hbar\omega}{E_0} \right)^2 \quad (15.85)$$

This means that our classical spectra (15.83) and (15.84) must be corrected by multiplication with (15.85) to take into account the kinematics of the neutrino emission. The modified classical photon spectrum is

$$N(\hbar\omega) = \frac{e^2}{2\pi\hbar c} \frac{\hbar\omega}{(mc^2)^2} \left(1 - \frac{\hbar\omega}{E_0} \right)^2 \quad (15.86)$$

This is essentially the correct quantum-mechanical result. A comparison of the corrected distribution (15.86) and the classical one (15.84) is shown in Fig. 15.12. Evidently the neutrino-emission probability is crucial in obtaining the proper behavior of the photon energy spectrum. For the customary bremsstrahlung spectra such correction factors are less important because the bulk of the radiation is emitted in photons with energies much smaller than the maximum allowable value.

The total radiation emitted in orbital electron capture is the sum of the contributions from the disappearance of the electric charge and of the magnetic moment. From the different behaviors of (15.79) and (15.86) we see that the

Fig. 15.12 Spectrum of photons emitted in orbital electron capture because of disappearance of the magnetic moment of the electron.

upper end of the spectrum will be dominated by the magnetic-moment contribution, unless the energy release is very small, whereas the lower end of the spectrum will be dominated by the electric-charge term, especially for high Z . Figure 15.13 shows a typical combined spectrum for $Z \sim 20$ – 30 . Observations on a number of nuclei confirm the general features of the spectra and allow determination of the energy release E_0 .

Fig. 15.13 Typical photon spectrum for radiative orbital electron capture with energy release E_0 , showing the contributions from the disappearance of the electronic charge and magnetic moment.

REFERENCES AND SUGGESTED READING

- Classical bremsstrahlung is discussed briefly by
 Landau and Lifshitz, *Classical Theory of Fields*, Section 9.4,
 Panofsky and Phillips, Section 19.6.
- A semiclassical discussion analogous to ours, but using impact parameters throughout and much briefer, appears in
 Rossi, Section 2.12.
- Bremsstrahlung can be described accurately only by a proper quantum-mechanical treatment. The standard reference is
 Heitler.
- The method of virtual quanta (Weizsäcker-Williams method) has only one proper reference, the classic article by
 Williams.
- Short discussions appear in
 Heitler, Appendix 6,
 Panofsky and Phillips, Section 18.5.
- The work of Fermi that predates by 10 years the Weizsäcker-Williams treatment is
 E. Fermi, *Zeit. Physik* **29**, 315 (1924).
- The limitations of Fermi's approach to energy loss were clarified through the use of quantum mechanics by
 E. J. Williams, *Proc. Roy. Soc. A* **139**, 163 (1933).
- Among the quantum-mechanical treatments of radiative beta processes, having comparisons with experiment in some cases, are those by
 C. S. W. Chang and D. L. Falkoff, *Phys. Rev.*, **76**, 365 (1949),
 P. C. Martin and R. J. Glauber, *Phys. Rev.*, **109**, 1307 (1958),
 Siegbahn, Chapter XX (III) by C. S. Wu.
- An important topic not mentioned so far is the production of coherent bremsstrahlung beams from high-energy electrons on crystals. Under proper conditions roughly monochromatic, highly polarized photon beams can be produced. A review of the theory and experiment is given by
 G. Diambrini Palazzi, *Rev. Mod. Phys.* **40**, 611 (1968).

PROBLEMS

- 15.1** A nonrelativistic particle of charge e and mass m collides with a fixed, smooth, hard sphere of radius R . Assuming that the collision is elastic, show that in the dipole approximation (neglecting retardation effects) the classical differential cross section for the emission of photons per unit solid angle per unit energy interval is

$$\frac{d^2\sigma}{d\Omega d(h\omega)} = \frac{R^2}{12\pi} \frac{e^2}{\hbar c} \left(\frac{v}{c}\right)^2 \frac{1}{\hbar\omega} (2 + 3 \sin^2 \theta)$$

where θ is measured relative to the incident direction. Sketch the angular distribution. Integrate over angles to get the total bremsstrahlung cross section. Qualitatively what factor (or factors) govern the upper limit to the frequency spectrum?

- 15.2** Treat the previous problem without the assumption of nonrelativistic motion, using (15.2) and assuming the elastic impact is of negligible duration. Show that the

cross section for photon emission is now

$$\frac{d^2\sigma}{d\Omega d(\hbar\omega)} = \frac{R^2}{4\pi} \frac{e^2}{\hbar c} \frac{\beta^2}{\hbar\omega} \left[\frac{\sin^2\theta}{(1-\beta\cos\theta)^2} + \frac{1}{\beta^3} \ln\left(\frac{1+\beta}{1-\beta}\right) - \frac{2}{\beta^2} \right]$$

- 15.3** A group of charged particles with charges e_i and coordinates $\mathbf{r}_i(t)$ undergo interactions and are accelerated only during a time $-\tau/2 < t < \tau/2$, during which their velocities change from $c\boldsymbol{\beta}_i$ to $c\boldsymbol{\beta}'_i$.

(a) Show that for $\omega\tau \ll 1$ the intensity of radiation emitted with polarization $\boldsymbol{\epsilon}$ per unit solid angle and unit frequency interval is

$$\frac{d^2I}{d\omega d\Omega} = \frac{1}{4\pi^2 c} |\boldsymbol{\epsilon}^* \cdot \mathbf{E}|^2$$

where

$$\mathbf{E} = \sum_i e_i \left(\frac{\boldsymbol{\beta}'_i}{1 - \mathbf{n} \cdot \boldsymbol{\beta}'_i} - \frac{\boldsymbol{\beta}_i}{1 - \mathbf{n} \cdot \boldsymbol{\beta}_i} \right) e^{-i\omega \mathbf{n} \cdot \mathbf{r}_i(0)/c}$$

(b) An ω^0 meson of mass 784 MeV decays into $\pi^+\pi^-$ and e^+e^- with branching ratios of 1.3×10^{-2} and 8×10^{-5} , respectively. Show that for both decay modes the frequency spectrum of radiated energy at low frequencies is

$$\frac{dI}{d\omega} = \frac{e^2}{\pi c} \left[\left(\frac{1+\beta^2}{\beta} \right) \ln\left(\frac{1+\beta}{1-\beta}\right) - 2 \right] \approx \frac{4e^2}{\pi c} \left[\ln\left(\frac{M_\omega}{m}\right) - \frac{1}{2} \right]$$

where M_ω is the mass of the ω^0 meson and m is the mass of one of the decay products. Evaluate approximately the *total* energy radiated in each decay by integrating the spectrum up to the maximum frequency allowed kinematically. What fraction of the rest energy of the ω^0 is it in each decay?

- 15.4** A situation closely related to that of Problem 15.3(b) is the emission of radiation caused by the disappearance of charges and magnetic moments in the annihilation of electrons and positrons to form hadrons in high-energy storage ring experiments. If the differential cross section for the process $e^+e^- \rightarrow \text{hadrons}$ is $d\sigma_0$, *without* the emission of photons, calculate the cross section for the same process accompanied by a soft photon ($\hbar\omega \rightarrow 0$) in the energy interval $d(\hbar\omega)$ around $\hbar\omega$. Compare your results with the quantum-mechanical expressions:

$$\frac{d^2\sigma}{d\Omega d(\hbar\omega)} = \frac{\alpha}{\pi^2} \frac{d\sigma_0(s')}{\hbar\omega} \sqrt{\frac{s'^2 - 4m^2 s'}{s^2 - 4m^2 s}} \cdot \frac{\left[\beta^2 \sin^2\theta + \frac{\hbar^2 \omega^2}{s' + 2m^2} (1 - \beta^4 \cos^4\theta) \right]}{(1 - \beta^2 \cos^2\theta)^2}$$

$$\frac{d\sigma}{d(\hbar\omega)} = \frac{4\alpha}{\pi} \frac{d\sigma_0(s')}{\hbar\omega} \sqrt{\frac{s'^2 - 4m^2 s'}{s^2 - 4m^2 s}} \left\{ \frac{1}{2} \left[\frac{1+\beta^2}{2\beta} \ln\left(\frac{1+\beta}{1-\beta}\right) - 1 \right] + \frac{\hbar^2 \omega^2}{s' + 2m^2} \left[\frac{1}{\beta} \ln\left(\frac{1+\beta}{1-\beta}\right) - 1 \right] \right\}$$

where $s = (p_1 + p_2)^2$, $s' = (p_1 + p_2 - k)^2$, $\beta = \text{electron } v/c \text{ in c.m. frame}$. Neglect the emission of radiation by any of the hadrons, all assumed to be much heavier than the electrons.

The factors proportional to ω^2 in the numerators of these expressions can be attributed to the disappearance of the magnetic moments. If you have not already included such contributions in your semiclassical calculation, you may consider doing it.

- 15.5** Two particles with charges q_1 and q_2 and masses m_1 and m_2 collide under the

action of electromagnetic (and perhaps other) forces. Consider the angular and frequency distributions of the radiation emitted in the collision.

(a) Show that for nonrelativistic motion the energy radiated per unit solid angle per unit frequency interval in the center of mass coordinate system is given by

$$\frac{d^2 I(\omega, \Omega)}{d\omega d\Omega} = \frac{\mu^2}{4\pi^2 c^3} \left| \int e^{-i\omega t} \ddot{\mathbf{x}} \times \mathbf{n} \left[\frac{q_1}{m_1} e^{i(\omega/c)(\mu/m_1)\mathbf{n} \cdot \mathbf{x}(t)} - \frac{q_2}{m_2} e^{-i(\omega/c)(\mu/m_2)\mathbf{n} \cdot \mathbf{x}(t)} \right] dt \right|^2$$

where $\mathbf{x} = (\mathbf{x}_1 - \mathbf{x}_2)$ is the relative coordinate, \mathbf{n} is a unit vector in the direction of observation, and $\mu = m_1 m_2 / (m_1 + m_2)$ is the reduced mass.

(b) By expanding the retardation factors show that, if the two particles have the same charge to mass ratio (e.g., a deuteron and an alpha particle), the leading (dipole) term vanishes and the next-order term gives

$$\frac{d^2 I(\omega, \Omega)}{d\omega d\Omega} = \frac{\omega^2}{4\pi^2 c^5} \left(\frac{q_1 \mu^2}{m_1^2} + \frac{q_2 \mu^2}{m_2^2} \right)^2 \left| \int e^{-i\omega t} (\mathbf{n} \cdot \mathbf{x}) (\ddot{\mathbf{x}} \times \mathbf{n}) dt \right|^2$$

(c) Relate result (b) to the multipole expansion of Sections 9.1–9.3.

15.6 Two identical point particles of charge q and mass m interact by means of a short-range repulsive interaction which is equivalent to a hard sphere of radius R in their relative separation. Neglecting the electromagnetic interaction between the two particles, determine the radiation cross section in the center of mass system for a collision between these identical particles to the lowest nonvanishing approximation. Show that the differential cross section for emission of photons per unit solid angle per unit energy interval is

$$\frac{d^2 \sigma}{d(\hbar\omega) d\Omega} = \frac{R^2}{60\pi} \left(\frac{q^2}{\hbar c} \right) \frac{v^2}{c^2} \left(\frac{R}{\hbar c} \right)^2 \hbar\omega [1 + \frac{5}{14} P_2(\cos \theta) - \frac{3}{28} P_4(\cos \theta)]$$

where θ is measured relative to the incident direction. Compare this result with that of Problem 15.1 as to frequency dependence, relative magnitude, etc.

15.7 A particle of charge ze , mass m , and nonrelativistic velocity v deflected in a screened Coulomb field, $V(r) = Zze^2 e^{-\alpha r}/r$, and consequently emits radiation. Discuss the radiation with the approximation that the particle moves in an almost straight-line trajectory past the force center.

(a) Show that, if the impact parameter is b , the energy radiated per unit frequency interval is

$$\frac{dI}{d\omega}(\omega, b) = \frac{8}{3\pi} \frac{Z^2 e^2}{c} \left(\frac{z^2 e^2}{mc^2} \right)^2 \left(\frac{c}{v} \right)^2 \alpha^2 K_1^2(\alpha b)$$

for $\omega \ll v/b$, and negligible for $\omega \gg v/b$.

(b) Show that the radiation cross section is

$$\frac{d\chi(\omega)}{d\omega} = -\frac{16}{3} \frac{Z^2 e^2}{c} \left(\frac{z^2 e^2}{mc^2} \right)^2 \left(\frac{c}{v} \right)^2 \left\{ \frac{x^2}{2} \left[K_0^2(x) - K_1^2(x) + \frac{2K_0(x)K_1(x)}{x} \right] \right\}_{x_1}^{x_2}$$

where $x_1 = \alpha b_{\min}$, $x_2 = \alpha b_{\max}$.

(c) With $b_{\min} = \hbar/mv$, $b_{\max} = v/\omega$, and $\alpha^{-1} = 1.4a_0 Z^{-1/3}$, determine the radiation cross section in the two limits, $x_2 \ll 1$ and $x_2 \gg 1$. Compare your results with the “screening” and “no screening” limits of the text.

15.8 A particle of charge ze , mass m , and velocity v is deflected in a hyperbolic path by

a fixed repulsive Coulomb potential, $V(r) = Ze^2/r$. In the nonrelativistic dipole approximation (but with no further approximations),

(a) show that the energy radiated per unit frequency interval by the particle when initially incident at impact parameter b is:

$$\frac{d}{d\omega} I(\omega, b) = \frac{8}{3\pi} \frac{(ze a \omega)^2}{c^3} e^{-(\pi\omega/\omega_0)} \left\{ \left[K'_{i\omega/\omega_0} \left(\frac{\omega\epsilon}{\omega_0} \right) \right]^2 + \frac{\epsilon^2 - 1}{\epsilon^2} \left[K_{i\omega/\omega_0} \left(\frac{\omega\epsilon}{\omega_0} \right) \right]^2 \right\}$$

(b) show that the radiation cross section is:

$$\frac{d}{d\omega} \chi(\omega) = \frac{16}{3} \frac{(zeav)^2}{c^3} e^{-(\pi\omega/\omega_0)} \frac{\omega}{\omega_0} K_{i\omega/\omega_0} \left(\frac{\omega}{\omega_0} \right) \left[-K'_{i\omega/\omega_0} \left(\frac{\omega}{\omega_0} \right) \right]$$

(c) Prove that the radiation cross section reduces to that obtained in the text for classical bremsstrahlung for $\omega \ll \omega_0$. What is the limiting form for $\omega \gg \omega_0$?

(d) What modifications occur for an attractive Coulomb interaction?

The hyperbolic path may be described by

$$x = a(\epsilon + \cosh \xi), \quad y = -b \sinh \xi, \quad \omega_0 t = (\xi + \epsilon \sinh \xi)$$

where $a = Ze^2/mv^2$, $\epsilon = \sqrt{1 + (b/a)^2}$, $\omega_0 = v/a$.

15.9 Using the method of virtual quanta, discuss the relationship between the cross section for photodisintegration of a nucleus and electrodisintegration of a nucleus.

(a) Show that, for electrons of energy $E = \gamma mc^2 \gg mc^2$, the electrodisintegration cross section is approximately:

$$\sigma_{el}(E) \approx \frac{2}{\pi} \frac{e^2}{\hbar c} \int_{\omega_T}^{E/\hbar} \sigma_{\text{photo}}(\omega) \ln \left(\frac{k\gamma^2 mc^2}{\hbar \omega} \right) \frac{d\omega}{\omega}$$

where $\hbar\omega_T$ is the threshold energy for the process.

(b) Assuming that $\sigma_{\text{photo}}(\omega)$ has the resonance shape:

$$\sigma_{\text{photo}}(\omega) \approx \frac{A}{2\pi} \frac{e^2}{Mc} \frac{\Gamma}{(\omega - \omega_0)^2 + (\Gamma/2)^2}$$

where the width Γ is small compared to $(\omega_0 - \omega_T)$, sketch the behavior of $\sigma_{el}(E)$ as a function of E and show that for $E \gg \hbar\omega_0$,

$$\sigma_{el}(E) \approx \frac{2}{\pi} \left(\frac{e^2}{\hbar c} \right) \frac{Ae^2}{Mc} \frac{1}{\omega_0} \ln \left(\frac{kE^2}{mc^2 \hbar \omega_0} \right)$$

(c) Discuss the experimental comparison between activities produced by bremsstrahlung spectra and monoenergetic electrons as presented by Brown and Wilson, *Phys. Rev.*, **93**, 443 (1954), and show that the quantity defined as $F_{\text{exp}}(Z, E)$ has the approximate value $8\pi/3$ at high energies if the Weizsäcker-Williams spectrum is used to describe both processes and the photodisintegration cross section has a resonance shape.

15.10 A fast particle of charge ze , mass M , velocity v , collides with a hydrogen-like atom with one electron of charge $-e$, mass m , bound to a nuclear center of charge Ze . The collisions can be divided into two kinds: close collisions where the particle passes through the atom ($b < d$), and distant collisions where the particle passes by outside the atom ($b > d$). The atomic "radius" d can be taken as a_0/Z . For the close collisions the interaction of the incident particle and the electron can be treated as a two-body collision and the energy transfer calculated from the Rutherford cross section. For the

distant collisions the excitation and ionization of the atom can be considered the result of the photoelectric effect by the virtual quanta of the incident particle's fields.

For simplicity assume that for photon energies Q greater than the ionization potential I the photoelectric cross section is

$$\sigma_v(Q) = \frac{8\pi^2}{137} \left(\frac{a_0}{Z} \right)^2 \left(\frac{I}{Q} \right)^3$$

(This obeys the empirical $Z^4\lambda^3$ law for X-ray absorption and has a coefficient adjusted to satisfy the dipole sum rule, $\int \sigma_v(Q) dQ = 2\pi^2 e^2 \hbar / mc$.)

(a) Calculate the differential cross sections $d\sigma/dQ$ for energy transfer Q for close and distant collisions (write them as functions of Q/I as far as possible and in units of $2\pi z^2 e^4 / mv^2 I^2$). Plot the two distributions for $Q/I > 1$ for nonrelativistic motion of the incident particle and $\frac{1}{2}mv^2 = 10^3 I$.

(b) Show that the number of distant collisions measured by the integrated cross section is much larger than the number of close collisions, but that the energy transfer per collision is much smaller. Show that the energy loss is divided approximately equally between the two kinds of collisions, and verify that your total energy loss is in essential agreement with Bethe's result (13.44).

15.11 In the decay of a pi meson at rest a mu meson and a neutrino are created. The total kinetic energy available is $(m_\pi - m_\mu)c^2 = 34$ MeV. The mu meson has a kinetic energy of 4.1 MeV. Determine the number of quanta emitted per unit energy interval because of the sudden creation of the moving mu meson. Assuming that the photons are emitted perpendicular to the direction of motion of the mu meson (actually it is a $\sin^2 \theta$ distribution), show that the maximum photon energy is 17 MeV. Find how many quanta are emitted with energies greater than one-tenth of the maximum, and compare your result with the observed ratio of radiative pi-mu decays. [W. F. Fry, *Phys. Rev.*, **86**, 418 (1952); H. Primakoff, *Phys. Rev.*, **84**, 1255 (1951).]

15.12 In internal conversion, the nucleus makes a transition from one state to another and an orbital electron is ejected. The electron has a kinetic energy equal to the transition energy minus its binding energy. For a conversion line of 1 MeV determine the number of quanta emitted per unit energy because of the sudden ejection of the electron. What fraction of the electrons will have energies less than 99 per cent of the total energy? Will this low-energy tail on the conversion line be experimentally observable?

15.13 One of the decay modes of a K^+ meson is the three-pion decay, $K^+ \rightarrow \pi^+ \pi^+ \pi^-$. The energy release is 75 MeV, small enough that the pions can be treated nonrelativistically in rough approximation.

(a) Show that the differential spectrum of radiated intensity at low frequencies in the K meson rest frame is approximately

$$\frac{d^2 I}{d\omega d\Omega} \approx \frac{2e^2}{\pi^2 c} \cdot \frac{T_-}{m_\pi c^2} \cdot \sin^2 \theta$$

where T_- is the kinetic energy of the negative pion and θ is the angle of emission of the photon relative to the momentum of the negative pion.

(b) Estimate the branching ratio for emission of a photon of energy greater than Δ relative to the nonradiative three-pion decay. What is its numerical value for $\Delta = 1$ MeV? 10 MeV?

15.14 One of the decay modes of the charged K meson ($M_K = 493.7$ MeV) is $K^+ \rightarrow \pi^+ \pi^0$

($M_{\pi^+} = 139.6$ MeV, $M_{\pi^0} = 135.0$ MeV). Inner bremsstrahlung is emitted by the creation of the positive pion. A study of this radiative decay mode has been made by Edwards et al., *Phys. Rev.* **D5**, 2720 (1972).

(a) Calculate the classical distribution in angle and frequency of soft photons and compare with the data of Fig. 6 of Edwards et al. Compute the classical distribution also for $\beta = 0.71$, corresponding to a charged pion of kinetic energy 58 MeV, and compare.

(b) Estimate the number of radiative decays for charged pion kinetic energies on the interval, $58 \text{ MeV} \leq T_{\pi} \leq 90 \text{ MeV}$, as a fraction of *all* K^+ decays (the $\pi^+\pi^0$ decay mode is 21 per cent of all decays). You can treat the kinematics, including the photon, correctly or can approximate reality with an idealization that has the neutral pion always with the same momentum and the photon and the charged pion with parallel momenta [see part (a) for justification of this assumption]. This idealization permits you to correlate directly the limits on the charged pion's kinetic energy with the photon's. Compare your estimate with the experimental value for the branching ratio for $\pi^+\pi^0\gamma$ (with the limited range of π^+ energies) of $(2.4 \pm 0.8) \times 10^{-4}$.

16

Multipole Fields

In Chapters 3 and 4 on electrostatics the spherical harmonic expansion of the scalar potential was used extensively for problems possessing some symmetry property with respect to an origin of coordinates. Not only was it useful in handling boundary-value problems in spherical coordinates, but with a source present it provided a systematic way of expanding the potential in terms of multipole moments of the charge density. For time-varying electromagnetic fields the scalar spherical harmonic expansion can be generalized to an expansion in vector spherical waves. These vector spherical waves are convenient for electromagnetic boundary-value problems possessing spherical symmetry properties and for the discussion of multipole radiation from a localized source distribution. In Chapter 9 we have already considered the simplest radiating multipole systems. In the present chapter we give a systematic development.

16.1 Basic Spherical Wave Solutions of the Scalar Wave Equation

As a prelude to the vector spherical wave problem, we consider the scalar wave equation. A scalar field $\psi(\mathbf{x}, t)$ satisfying the source-free wave equation,

$$\nabla^2 \psi - \frac{1}{c^2} \frac{\partial^2 \psi}{\partial t^2} = 0 \quad (16.1)$$

can be Fourier-analyzed in time as

$$\psi(\mathbf{x}, t) = \int_{-\infty}^{\infty} \psi(\mathbf{x}, \omega) e^{-i\omega t} d\omega \quad (16.2)$$

with each Fourier component satisfying the Helmholtz wave equation,

$$(\nabla^2 + k^2)\psi(\mathbf{x}, \omega) = 0 \quad (16.3)$$

with $k^2 = \omega^2/c^2$. For problems possessing symmetry properties about some origin it is convenient to have fundamental solutions appropriate to spherical coordinates. The representation of the Laplacian operator in spherical coordinates is given in equation (3.1). The separation of the angular and radial variables follows the well-known expansion,

$$\psi(\mathbf{x}, \omega) = \sum_{l,m} f_{lm}(r) Y_{lm}(\theta, \phi) \quad (16.4)$$

where the spherical harmonics Y_{lm} are defined by (3.53). The radial functions $f_{lm}(r)$ satisfy the radial equation, independent of m ,

$$\left[\frac{d^2}{dr^2} + \frac{2}{r} \frac{d}{dr} + k^2 - \frac{l(l+1)}{r^2} \right] f_l(r) = 0 \quad (16.5)$$

With the substitution,

$$f_l(r) = \frac{1}{r^{1/2}} u_l(r) \quad (16.6)$$

equation (16.5) is transformed into

$$\left[\frac{d^2}{dr^2} + \frac{1}{r} \frac{d}{dr} + k^2 - \frac{(l+\frac{1}{2})^2}{r^2} \right] u_l(r) = 0 \quad (16.7)$$

This equation is just the Bessel equation (3.75) with $\nu = l + \frac{1}{2}$. Thus the solutions for $f_{lm}(r)$ are

$$f_l(r) = \frac{A_{lm}}{r^{1/2}} J_{l+1/2}(kr) + \frac{B_{lm}}{r^{1/2}} N_{l+1/2}(kr) \quad (16.8)$$

It is customary to define *spherical Bessel and Hankel functions*, denoted by $j_l(x)$, $n_l(x)$, $h_l^{(1,2)}(x)$, as follows:

$$\left. \begin{aligned} j_l(x) &= \left(\frac{\pi}{2x} \right)^{1/2} J_{l+1/2}(x) \\ n_l(x) &= \left(\frac{\pi}{2x} \right)^{1/2} N_{l+1/2}(x) \\ h_l^{(1,2)}(x) &= \left(\frac{\pi}{2x} \right)^{1/2} [J_{l+1/2}(x) \pm iN_{l+1/2}(x)] \end{aligned} \right\} \quad (16.9)$$

For real x , $h_l^{(2)}(x)$ is the complex conjugate of $h_l^{(1)}(x)$. From the series expansions (3.82) and (3.83) one can show that

$$\left. \begin{aligned} j_l(x) &= (-x)^l \left(\frac{1}{x} \frac{d}{dx} \right)^l \left(\frac{\sin x}{x} \right) \\ n_l(x) &= -(-x)^l \left(\frac{1}{x} \frac{d}{dx} \right)^l \left(\frac{\cos x}{x} \right) \end{aligned} \right\} \quad (16.10)$$

For the first few values of l the explicit forms are:

$$\left. \begin{aligned}
 j_0(x) &= \frac{\sin x}{x}, & n_0(x) &= -\frac{\cos x}{x}, & h_0^{(1)}(x) &= \frac{e^{ix}}{ix} \\
 j_1(x) &= \frac{\sin x}{x^2} - \frac{\cos x}{x}, & n_1(x) &= -\frac{\cos x}{x^2} - \frac{\sin x}{x} \\
 h_1^{(1)}(x) &= -\frac{e^{ix}}{x} \left(1 + \frac{i}{x}\right) \\
 j_2(x) &= \left(\frac{3}{x^3} - \frac{1}{x}\right) \sin x - \frac{3 \cos x}{x^2}, & n_2(x) &= -\left(\frac{3}{x^3} - \frac{1}{x}\right) \cos x - 3 \frac{\sin x}{x^2} \\
 h_2^{(1)}(x) &= \frac{ie^{ix}}{x} \left(1 + \frac{3i}{x} - \frac{3}{x^2}\right) \\
 j_3(x) &= \left(\frac{15}{x^4} - \frac{6}{x^2}\right) \sin x - \left(\frac{15}{x^3} - \frac{1}{x}\right) \cos x \\
 n_3(x) &= -\left(\frac{15}{x^4} - \frac{6}{x^2}\right) \cos x - \left(\frac{15}{x^3} - \frac{1}{x}\right) \sin x \\
 h_3^{(1)}(x) &= \frac{e^{ix}}{x} \left(1 + \frac{6i}{x} - \frac{15}{x^2} - \frac{15i}{x^3}\right)
 \end{aligned} \right\} \quad (16.11)$$

From the series (3.82), (3.83), and the definition (3.85) it is possible to calculate the small argument limits to be

$$x \ll 1, l$$

$$\begin{aligned}
 j_l(x) &\rightarrow \frac{x^l}{(2l+1)!!} \left(1 - \frac{x^2}{2(2l+3)} + \cdots\right) \\
 n_l(x) &\rightarrow -\frac{(2l-1)!!}{x^{l+1}} \left(1 - \frac{x^2}{2(1-2l)} + \cdots\right)
 \end{aligned} \quad (16.12)$$

where $(2l+1)!! = (2l+1)(2l-1)(2l-3) \cdots (5) \cdot (3) \cdot (1)$. Similarly the large argument limits are

$$x \gg l$$

$$\left. \begin{aligned}
 j_l(x) &\rightarrow \frac{1}{x} \sin \left(x - \frac{l\pi}{2}\right) \\
 n_l(x) &\rightarrow -\frac{1}{x} \cos \left(x - \frac{l\pi}{2}\right) \\
 h_l^{(1)}(x) &\rightarrow (-i)^{l+1} \frac{e^{ix}}{x}
 \end{aligned} \right\} \quad (16.13)$$

The spherical Bessel functions satisfy the recursion formulas,

$$\left. \begin{aligned}
 \frac{2l+1}{x} z_l(x) &= z_{l-1}(x) + z_{l+1}(x) \\
 z'_l(x) &= \frac{1}{2l+1} [l z_{l-1}(x) - (l+1) z_{l+1}(x)]
 \end{aligned} \right\} \quad (16.14)$$

where $z_i(x)$ is any one of the functions $j_i(x)$, $n_i(x)$, $h_i^{(1)}(x)$, $h_i^{(2)}(x)$. The Wronskians of the various pairs are

$$W(j_i, n_i) = \frac{1}{i} W(j_i, h_i^{(1)}) = -W(n_i, h_i^{(1)}) = \frac{1}{x^2} \quad (16.15)$$

The general solution of (16.3) in spherical coordinates can be written

$$\psi(\mathbf{x}) = \sum_{l,m} [A_{lm}^{(1)} h_l^{(1)}(kr) + A_{lm}^{(2)} h_l^{(2)}(kr)] Y_{lm}(\theta, \phi) \quad (16.16)$$

where the coefficients $A_{lm}^{(1)}$ and $A_{lm}^{(2)}$ will be determined by the boundary conditions.

For reference purposes we present the spherical wave expansion for the outgoing wave Green function $G(\mathbf{x}, \mathbf{x}')$, which is appropriate to the equation,

$$(\nabla^2 + k^2)G(\mathbf{x}, \mathbf{x}') = -\delta(\mathbf{x} - \mathbf{x}') \quad (16.17)$$

in the infinite domain. This Green function, as was shown in Chapter 6, is

$$G(\mathbf{x}, \mathbf{x}') = \frac{e^{ik|\mathbf{x} - \mathbf{x}'|}}{4\pi |\mathbf{x} - \mathbf{x}'|} \quad (16.18)$$

The spherical wave expansion for $G(\mathbf{x}, \mathbf{x}')$ can be obtained in exactly the same way as was done in Section 3.9 for the Poisson equation [see especially equation (3.117) and below]. An expansion of the form,

$$G(\mathbf{x}, \mathbf{x}') = \sum_{l,m} g_l(r, r') Y_{lm}^*(\theta', \phi') Y_{lm}(\theta, \phi) \quad (16.19)$$

substituted into (16.17) leads to an equation for $g_l(r, r')$:

$$\left[\frac{d^2}{dr^2} + \frac{2}{r} \frac{d}{dr} + k^2 - \frac{l(l+1)}{r^2} \right] g_l = -\frac{1}{r^2} \delta(r - r') \quad (16.20)$$

The solution which satisfies the boundary conditions of finiteness at the origin and outgoing waves at infinity is

$$g_l(r, r') = A j_l(kr_{<}) h_l^{(1)}(kr_{>}) \quad (16.21)$$

The correct discontinuity in slope is assured if $A = ik$. Thus the expansion of the Green function is

$$\frac{e^{ik|\mathbf{x} - \mathbf{x}'|}}{4\pi |\mathbf{x} - \mathbf{x}'|} = ik \sum_{l=0}^{\infty} j_l(kr_{<}) h_l^{(1)}(kr_{>}) \sum_{m=-l}^l Y_{lm}^*(\theta', \phi') Y_{lm}(\theta, \phi) \quad (16.22)$$

Our emphasis so far has been on the radial functions appropriate to the scalar wave equation. We now re-examine the angular functions in order to introduce some concepts of use in considering the vector wave equation. The basic angular functions are the spherical harmonics $Y_{lm}(\theta, \phi)$ (3.53), which are solutions of the

equation,

$$-\left[\frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right) + \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \phi^2} \right] Y_{lm} = l(l+1) Y_{lm} \quad (16.23)$$

As is well known in quantum mechanics, this equation can be written in the form:

$$L^2 Y_{lm} = l(l+1) Y_{lm} \quad (16.24)$$

The differential operator $L^2 = L_x^2 + L_y^2 + L_z^2$, where

$$\mathbf{L} = \frac{1}{i} (\mathbf{r} \times \nabla) \quad (16.25)$$

is \hbar^{-1} times the orbital angular-momentum operator of wave mechanics.

The components of \mathbf{L} can be written conveniently in the combinations,

$$\left. \begin{aligned} L_+ &= L_x + iL_y = e^{i\phi} \left(\frac{\partial}{\partial \theta} + i \cot \theta \frac{\partial}{\partial \phi} \right) \\ L_- &= L_x - iL_y = e^{-i\phi} \left(-\frac{\partial}{\partial \theta} + i \cot \theta \frac{\partial}{\partial \phi} \right) \\ L_z &= -i \frac{\partial}{\partial \phi} \end{aligned} \right\} \quad (16.26)$$

We note that \mathbf{L} operates only on angular variables and is independent of r . From definition (16.25) it is evident that

$$\mathbf{r} \cdot \mathbf{L} = 0 \quad (16.27)$$

holds as an operator equation. From the explicit forms (16.26) it is easy to verify that L^2 is equal to the operator on the left side of (16.23).

From the explicit forms (16.26) and recursion relations for Y_{lm} the following useful relations can be established:

$$\left. \begin{aligned} L_+ Y_{lm} &= \sqrt{(l-m)(l+m+1)} Y_{l,m+1} \\ L_- Y_{lm} &= \sqrt{(l+m)(l-m+1)} Y_{l,m-1} \\ L_z Y_{lm} &= m Y_{lm} \end{aligned} \right\} \quad (16.28)$$

Finally we note the following operator equations concerning the commutation properties of \mathbf{L} , L^2 , and ∇^2 :

$$\left. \begin{aligned} L^2 \mathbf{L} &= \mathbf{L} L^2 \\ \mathbf{L} \times \mathbf{L} &= i\mathbf{L} \\ L_j \nabla^2 &= \nabla^2 L_j \end{aligned} \right\} \quad (16.29)$$

where

$$\nabla^2 = \frac{1}{r} \frac{\partial^2}{\partial r^2} (r) - \frac{L^2}{r^2} \quad (16.30)$$

16.2 Multipole Expansion of the Electromagnetic Fields

With the assumption of a time dependence $e^{-i\omega t}$ the Maxwell equations in a sourcefree region of empty space are

$$\begin{aligned}\nabla \times \mathbf{E} &= ik\mathbf{B}, & \nabla \times \mathbf{B} &= -ik\mathbf{E} \\ \nabla \cdot \mathbf{E} &= 0 & \nabla \cdot \mathbf{B} &= 0\end{aligned}\quad (16.31)$$

where $k = \omega/c$. If \mathbf{E} is eliminated by combining the two curl equations, we obtain for \mathbf{B} ,

$$\left. \begin{aligned}(\nabla^2 + k^2)\mathbf{B} &= 0, & \nabla \cdot \mathbf{B} &= 0 \\ \mathbf{E} &= \frac{i}{k} \nabla \times \mathbf{B}\end{aligned} \right\} \quad (16.32)$$

with \mathbf{E} given by

Alternatively, \mathbf{B} can be eliminated to yield

$$\left. \begin{aligned}(\nabla^2 + k^2)\mathbf{E} &= 0, & \nabla \cdot \mathbf{E} &= 0 \\ \mathbf{B} &= -\frac{i}{k} \nabla \times \mathbf{E}\end{aligned} \right\} \quad (16.33)$$

with \mathbf{B} given by

Either (16.32) or (16.33) is a set of three equations that is equivalent to the Maxwell equations (16.31).

We wish to find multipole solutions for \mathbf{E} and \mathbf{B} . From (16.32) and (16.33) it is evident that each *Cartesian* component of \mathbf{B} and \mathbf{E} satisfies the Helmholtz wave equation (16.3). Hence each such component can be written as an expansion of the general form (16.16). There remains, however, the problem of orchestrating the different components in order to satisfy $\nabla \cdot \mathbf{B} = 0$ and $\nabla \cdot \mathbf{E} = 0$ and to give a pure multipole field of order (l, m) . We follow a different and somewhat easier path suggested by Bouwkamp and Casimir.* Consider the scalar quantity $\mathbf{r} \cdot \mathbf{A}$, where \mathbf{A} is a well-behaved vector field. It is straightforward to verify that the Laplacian operator acting on this scalar gives

$$\nabla^2(\mathbf{r} \cdot \mathbf{A}) = \mathbf{r} \cdot (\nabla^2 \mathbf{A}) + 2\nabla \cdot \mathbf{A} \quad (16.34)$$

From (16.32) and (16.33) it therefore follows that the scalars, $\mathbf{r} \cdot \mathbf{E}$ and $\mathbf{r} \cdot \mathbf{B}$, both satisfy the Helmholtz wave equation:

$$(\nabla^2 + k^2)(\mathbf{r} \cdot \mathbf{E}) = 0, \quad (\nabla^2 + k^2)(\mathbf{r} \cdot \mathbf{B}) = 0 \quad (16.35)$$

The general solution for $\mathbf{r} \cdot \mathbf{E}$ is given by (16.16), and similarly for $\mathbf{r} \cdot \mathbf{B}$.

* C. J. Bouwkamp and H. B. G. Casimir, *Physica* **20**, 539 (1954). This paper discusses the relationship among a number of different, but equivalent, approaches to multipole radiation.

We now define a magnetic multipole field of order (l, m) by the conditions,

$$\left. \begin{aligned} \mathbf{r} \cdot \mathbf{B}_{lm}^{(M)} &= \frac{l(l+1)}{k} g_l(kr) Y_{lm}(\theta, \phi) \\ \mathbf{r} \cdot \mathbf{E}_{lm}^{(M)} &= 0 \end{aligned} \right\} \quad (16.36)$$

where

$$g_l(kr) = A_l^{(1)} h_l^{(1)}(kr) + A_l^{(2)} h_l^{(2)}(kr) \quad (16.37)$$

The presence of the factor of $l(l+1)/k$ is for later convenience. Using the curl equation in (16.33) we can relate $\mathbf{r} \cdot \mathbf{B}$ to the electric field:

$$k \mathbf{r} \cdot \mathbf{B} = \frac{1}{i} \mathbf{r} \cdot (\nabla \times \mathbf{E}) = \frac{1}{i} (\mathbf{r} \times \nabla) \cdot \mathbf{E} = \mathbf{L} \cdot \mathbf{E} \quad (16.38)$$

where \mathbf{L} is given by (16.25). With $\mathbf{r} \cdot \mathbf{B}$ given by (16.36), the electric field of the magnetic multipole must satisfy

$$\mathbf{L} \cdot \mathbf{E}_{lm}^{(M)}(r, \theta, \phi) = l(l+1) g_l(kr) Y_{lm}(\theta, \phi) \quad (16.39)$$

and $\mathbf{r} \cdot \mathbf{E}_{lm}^{(M)} = 0$. To determine the purely transverse electric field from (16.39), we first observe that the operator \mathbf{L} acts only on the angular variables (θ, ϕ) . This means that the radial dependence of $\mathbf{E}_{lm}^{(M)}$ must be given by $g_l(kr)$. Second, the operator \mathbf{L} acting on Y_{lm} transforms the m value according to (16.28), but does not change the l value. Thus the components of $\mathbf{E}_{lm}^{(M)}$ can be at most linear combinations of Y_{lm} 's with different m values and a common l , equal to the l value on the right-hand side of (16.39). A moment's thought shows that in order for $\mathbf{L} \cdot \mathbf{E}_{lm}^{(M)}$ to yield a single Y_{lm} , it is necessary to prepare the components of $\mathbf{E}_{lm}^{(M)}$ beforehand to compensate for whatever raising or lowering of m values is done by \mathbf{L} . Thus, in the term $L_- E_+$, for example, it must be that E_+ is proportional to $L_+ Y_{lm}$. What this amounts to is that the electric field should be

$$\left. \begin{aligned} \mathbf{E}_{lm}^{(M)} &= g_l(kr) \mathbf{L} Y_{lm}(\theta, \phi) \\ \mathbf{B}_{lm}^{(M)} &= -\frac{i}{k} \nabla \times \mathbf{E}_{lm}^{(M)} \end{aligned} \right\} \quad (16.40)$$

Together with

(16.40) specifies the electromagnetic fields of a magnetic multipole of order (l, m) . Because the electric field (16.40) is transverse to the radius vector, these multipole fields are sometimes called *transverse electric (TE)* rather than magnetic.

The fields of an *electric or transverse magnetic (TM) multipole of order (l, m)* are specified similarly by the conditions,

$$\left. \begin{aligned} \mathbf{r} \cdot \mathbf{E}_{lm}^{(E)} &= -\frac{l(l+1)}{k} f_l(kr) Y_{lm}(\theta, \phi) \\ \mathbf{r} \cdot \mathbf{B}_{lm}^{(E)} &= 0 \end{aligned} \right\} \quad (16.41)$$

Then the *electric* multipole fields are

$$\left. \begin{aligned} \mathbf{B}_{lm}^{(E)} &= f_l(kr) \mathbf{L} Y_{lm}(\theta, \phi) \\ \mathbf{E}_{lm}^{(E)} &= \frac{i}{k} \nabla \times \mathbf{B}_{lm}^{(E)} \end{aligned} \right\} \quad (16.42)$$

The radial function $f_l(kr)$ is given by an expression like (16.37).

The fields (16.40) and (16.42) are the spherical wave analogues of the TE and TM cylindrical modes of Chapter 8. Just as in the cylindrical waveguide, the two sets of multipole fields (16.40) and (16.42) can be shown to form a complete set of vector solutions to the Maxwell equations in a sourcefree region. The terminology electric and magnetic multipole fields will be used, rather than TM and TE, since the sources of each type of field will be seen to be the electric-charge density and the magnetic-moment density, respectively. Since the vector spherical harmonic, $\mathbf{L} Y_{lm}$, plays an important role, it is convenient to introduce the normalized form,*

$$\mathbf{X}_{lm}(\theta, \phi) = \frac{1}{\sqrt{l(l+1)}} \mathbf{L} Y_{lm}(\theta, \phi) \quad (16.43)$$

with the orthogonality properties,

$$\int \mathbf{X}_{l'm'}^* \cdot \mathbf{X}_{lm} d\Omega = \delta_{ll'} \delta_{mm'} \quad (16.44)$$

and

$$\int \mathbf{X}_{l'm'}^* \cdot (\mathbf{r} \times \mathbf{X}_{lm}) d\Omega = 0 \quad (16.45)$$

for all l, l', m, m' .

By combining the two types of fields we can write the general solution to the Maxwell equations (16.31):

$$\left. \begin{aligned} \mathbf{B} &= \sum_{l,m} \left[a_E(l, m) f_l(kr) \mathbf{X}_{lm} - \frac{i}{k} a_M(l, m) \nabla \times g_l(kr) \mathbf{X}_{lm} \right] \\ \mathbf{E} &= \sum_{l,m} \left[\frac{i}{k} a_E(l, m) \nabla \times f_l(kr) \mathbf{X}_{lm} + a_M(l, m) g_l(kr) \mathbf{X}_{lm} \right] \end{aligned} \right\} \quad (16.46)$$

where the coefficients $a_E(l, m)$ and $a_M(l, m)$ specify the amounts of electric (l, m) multipole and magnetic (l, m) multipole fields. The radial functions $f_l(kr)$ and $g_l(kr)$ are of the form (16.37). The coefficients $a_E(l, m)$ and $a_M(l, m)$, as well as the relative proportions in (16.37), are determined by the sources and boundary conditions. To make this explicit, we note that the scalars $\mathbf{r} \cdot \mathbf{B}$ and $\mathbf{r} \cdot \mathbf{E}$ are

* \mathbf{X}_{lm} is defined to be identically zero for $l=0$. Spherically symmetric solutions to the sourcefree Maxwell's equations exist only in the static limit $k \rightarrow 0$. See Section 9.1.

sufficient to determine the unknowns in (16.46) according to

$$\left. \begin{aligned} a_M(l, m)g_l(kr) &= \frac{k}{\sqrt{l(l+1)}} \int Y_{lm}^* \mathbf{r} \cdot \mathbf{B} \, d\Omega \\ a_E(l, m)f_l(kr) &= -\frac{k}{\sqrt{l(l+1)}} \int Y_{lm}^* \mathbf{r} \cdot \mathbf{E} \, d\Omega \end{aligned} \right\} \quad (16.47)$$

Knowledge of $\mathbf{r} \cdot \mathbf{B}$ and $\mathbf{r} \cdot \mathbf{E}$ at two different radii, r_1 and r_2 , in a sourcefree region will therefore permit a complete specification of the fields, including determination of the relative proportions of $h_l^{(1)}$ and $h_l^{(2)}$ in f_l and g_l . The use of the scalars $\mathbf{r} \cdot \mathbf{B}$ and $\mathbf{r} \cdot \mathbf{E}$ permits the connection between the sources ρ , \mathbf{J} and the multipole coefficients $a_E(l, m)$ and $a_M(l, m)$ to be established with relative ease (see Section 16.5).

16.3 Properties of Multipole Fields, Energy and Angular Momentum of Multipole Radiation

Before considering the connection between the general solution (16.46) and a localized source distribution, we examine the properties of the individual multipole fields (16.40) and (16.42). In the near zone ($kr \ll 1$) the radial function $f_l(kr)$ is proportional to n_l , given by (16.12), unless its coefficient vanishes identically. Excluding this possibility, the limiting behavior of the magnetic induction for an electric (l, m) multipole is

$$\mathbf{B}_{lm}^{(E)} \rightarrow -\frac{k}{l} \mathbf{L} \frac{Y_{lm}}{r^{l+1}} \quad (16.48)$$

where the proportionality coefficient is chosen for later convenience. To find the electric field we must take the curl of the right-hand side. A useful operator identity is

$$i\nabla \times \mathbf{L} = \mathbf{r}\nabla^2 - \nabla \left(1 + r \frac{\partial}{\partial r} \right) \quad (16.49)$$

The electric field (16.42) is

$$\mathbf{E}_{lm}^{(E)} \rightarrow \frac{-i}{l} \nabla \times \mathbf{L} \left(\frac{Y_{lm}}{r^{l+1}} \right) \quad (16.50)$$

Since (Y_{lm}/r^{l+1}) is a solution of the Laplace equation, the first term in (16.49) vanishes. Consequently the electric field at close distances for an electric (l, m) multipole is

$$\mathbf{E}_{lm}^{(E)} \rightarrow -\nabla \left(\frac{Y_{lm}}{r^{l+1}} \right) \quad (16.51)$$

This is exactly the electrostatic multipole field of Section 4.1. We note that the magnetic induction $\mathbf{B}_{lm}^{(E)}$ is smaller in magnitude than $\mathbf{E}_{lm}^{(E)}$ by a factor kr . Hence, in the near zone, the magnetic induction of an electric multipole is always much smaller than the electric field. For the magnetic multipole fields (16.40) evidently

the roles of \mathbf{E} and \mathbf{B} are interchanged according to the transformation,

$$\mathbf{E}^{(E)} \rightarrow -\mathbf{B}^{(M)}, \quad \mathbf{B}^{(E)} \rightarrow \mathbf{E}^{(M)} \quad (16.52)$$

In the far or radiation zone ($kr \gg 1$) the multipole fields depend on the boundary conditions imposed. For definiteness we consider the example of outgoing waves, appropriate to radiation by a localized source. Then the radial function $f_l(kr)$ is proportional to the spherical Hankel function $h_l^{(1)}(kr)$. From the asymptotic form (16.13) we see that in the radiation zone the magnetic induction for an electric (l, m) multipole goes as

$$\mathbf{B}_{lm}^{(E)} \rightarrow (-i)^{l+1} \frac{e^{ikr}}{kr} \mathbf{L} Y_{lm} \quad (16.53)$$

Then the electric field can be written

$$\mathbf{E}_{lm}^{(E)} = \frac{(-i)^l}{k^2} \left[\nabla \left(\frac{e^{ikr}}{r} \right) \times \mathbf{L} Y_{lm} + \frac{e^{ikr}}{r} \nabla \times \mathbf{L} Y_{lm} \right] \quad (16.54)$$

Since we have already used the asymptotic form of the spherical Hankel function, we are not justified in keeping higher powers in $(1/r)$ than the first. With this restriction and use of the identity (16.49) we find

$$\mathbf{E}_{lm}^{(E)} = -(-i)^{l+1} \frac{e^{ikr}}{kr} \left[\mathbf{n} \times \mathbf{L} Y_{lm} - \frac{1}{k} (\mathbf{r} \nabla^2 - \nabla) Y_{lm} \right] \quad (16.55)$$

where $\mathbf{n} = (\mathbf{r}/r)$ is a unit vector in the radial direction. The second term is evidently $1/kr$ times some dimensionless function of angles and can be omitted in the limit $kr \gg 1$. Then we find that the electric field in the radiation zone is

$$\mathbf{E}_{lm}^{(E)} = \mathbf{B}_{lm}^{(E)} \times \mathbf{n} \quad (16.56)$$

where $\mathbf{B}_{lm}^{(E)}$ is given by (16.53). These fields are typical radiation fields, transverse to the radius vector and falling off as r^{-1} . For magnetic multipoles we merely make the interchanges (16.52).

The multipole fields of a radiating source can be used to calculate the energy and angular momentum carried off by the radiation. For definiteness we consider a linear superposition of electric (l, m) multipoles with different m values, but all having the same l , and, following (16.46), write the fields as

$$\left. \begin{aligned} \mathbf{B}_l &= \sum_m a_E(l, m) \mathbf{X}_{lm} h_l^{(1)}(kr) e^{-i\omega t} \\ \mathbf{E}_l &= \frac{i}{k} \nabla \times \mathbf{B}_l \end{aligned} \right\} \quad (16.57)$$

For harmonically varying fields the time-averaged energy density is

$$u = \frac{1}{16\pi} (\mathbf{E} \cdot \mathbf{E}^* + \mathbf{B} \cdot \mathbf{B}^*) \quad (16.58)$$

In the radiation zone the two terms are equal. Consequently the energy in a

spherical shell between r and $(r+dr)$ (for $kr \gg 1$) is

$$dU = \frac{dr}{8\pi k^2} \sum_{m,m'} a_E^*(l, m') a_E(l, m) \int \mathbf{X}_{lm'}^* \cdot \mathbf{X}_{lm} d\Omega \quad (16.59)$$

where the asymptotic form (16.13) of the spherical Hankel function has been used. With the orthogonality integral (16.44) this becomes

$$\frac{dU}{dr} = \frac{1}{8\pi k^2} \sum_m |a_E(l, m)|^2 \quad (16.60)$$

independent of the radius. For a general superposition of electric and magnetic multipoles the sum over m becomes a sum over l and m and $|a_E|^2$ becomes $|a_E|^2 + |a_M|^2$. The total energy is a spherical shell in the radiation zone is thus an *incoherent sum* over all multipoles.

The time-averaged angular-momentum density is

$$\mathbf{m} = \frac{1}{8\pi c} \operatorname{Re} [\mathbf{r} \times (\mathbf{E} \times \mathbf{B}^*)] \quad (16.61)$$

The triple cross product can be expanded and the electric field (16.57) substituted to yield, for a superposition of electric multipoles,

$$\mathbf{m} = \frac{1}{8\pi\omega} \operatorname{Re} [\mathbf{B}^*(\mathbf{L} \cdot \mathbf{B})] \quad (16.62)$$

Then the angular momentum in a spherical shell between r and $(r+dr)$ in the radiation zone is

$$d\mathbf{M} = \frac{dr}{8\pi\omega k^2} \operatorname{Re} \sum_{m,m'} a_E^*(l, m') a_E(l, m) \int (\mathbf{L} \cdot \mathbf{X}_{lm'})^* \mathbf{X}_{lm} d\Omega \quad (16.63)$$

With the explicit form (16.43) for \mathbf{X}_{lm} , (16.63) can be written

$$\frac{d\mathbf{M}}{dr} = \frac{1}{8\pi\omega k^2} \operatorname{Re} \sum_{m,m'} a_E^*(l, m') a_E(l, m) \int \mathbf{Y}_{lm'}^* \mathbf{L} \mathbf{Y}_{lm} d\Omega \quad (16.64)$$

From the properties of $\mathbf{L} \mathbf{Y}_{lm}$ listed in (16.28) and the orthogonality of the spherical harmonics we obtain the following expressions for the Cartesian components of $d\mathbf{M}/dr$:

$$\begin{aligned} \frac{dM_x}{dr} = & \frac{1}{16\pi\omega k^2} \operatorname{Re} \sum_m [\sqrt{(l-m)(l+m+1)} a_E^*(l, m+1) \\ & + \sqrt{(l+m)(l-m+1)} a_E^*(l, m-1)] a_E(l, m) \end{aligned} \quad (16.65)$$

$$\begin{aligned} \frac{dM_y}{dr} = & \frac{1}{16\pi\omega k^2} \operatorname{Im} \sum_m [\sqrt{(l-m)(l+m+1)} a_E^*(l, m+1) \\ & - \sqrt{(l+m)(l-m+1)} a_E^*(l, m-1)] a_E(l, m) \end{aligned} \quad (16.66)$$

$$\frac{dM_z}{dr} = \frac{1}{8\pi\omega k^2} \sum_m m |a_E(l, m)|^2 \quad (16.67)$$

These equations show that for a general l th order electric multipole that consists of a superposition of different m values only the z component of angular momentum is relatively simple.

For a multipole with a single m value, M_x and M_y vanish, while a comparison of (16.67) and (16.60) shows that

$$\frac{dM_z}{dr} = \frac{m}{\omega} \frac{dU}{dr} \quad (16.68)$$

independent of r . This has the obvious quantum interpretation that the radiation from a multipole of order (l, m) carries off $m\hbar$ units of z component of angular momentum per photon of energy $\hbar\omega$. Even with a superposition of different m values, the same interpretation of (16.67) holds, with each multipole of definite m contributing *incoherently* its share of the z component of angular momentum. Now, however, the x and y components are in general nonvanishing, with multipoles of adjacent m values contributing in a weighted coherent sum. The behavior contained in (16.64) and exhibited explicitly in (16.65)–(16.67) is familiar in the quantum mechanics of a vector operator and its representation with respect to basis states of J^2 and J_z .^{*} The angular momentum of multipole fields affords a classical example of this behavior, with the z component being diagonal in the (l, m) multipole basis and the x and y components not.

The characteristics of the angular momentum just presented hold true generally, even though our example (16.57) was somewhat specialized. For a superposition of both electric and magnetic multipoles of various (l, m) values, the angular momentum expression (16.63) is generalized to

$$\begin{aligned} \frac{d\mathbf{M}}{dr} = \frac{1}{8\pi\omega k^2} \operatorname{Re} \sum_{\substack{l,m \\ l',m'}} \bigg\{ & [a_E^*(l', m')a_E(l, m) + a_M^*(l', m')a_M(l, m)] \int (\mathbf{L} \cdot \mathbf{X}_{l'm'})^* \mathbf{X}_{lm} d\Omega \\ & + [a_E^*(l', m')a_M(l, m) - a_M^*(l', m')a_E(l, m)] \int (\mathbf{L} \cdot \mathbf{X}_{l'm'}) \mathbf{n} \times \mathbf{X}_{lm} d\Omega \bigg\} \quad (16.69) \end{aligned}$$

The first term in (16.69) is of the same form as (16.63) and represents the sum of the electric and magnetic multipoles separately. The second term is an interference between electric and magnetic multipoles. Examination of the structure of its angular integral shows that the interference is between electric and magnetic multipoles whose l values differ by unity. This is a necessary consequence of the parity properties of the multipole fields (see below). Apart from this complication of interference, the properties of $d\mathbf{M}/dr$ are as before.

The quantum-mechanical interpretation of (16.68) concerned the z component of angular momentum carried off by each photon. In further analogy with quantum mechanics we would expect the ratio of the square of the angular

^{*} See, for example, E. U. Condon and G. H. Shortley, *The Theory of Atomic Spectra*, Cambridge University Press, (1953), p. 63.

momentum to the square of the energy to have the value,

$$\frac{M^{(q)2}}{U^2} = \frac{(M_x^2 + M_y^2 + M_z^2)_q}{U^2} = \frac{l(l+1)}{\omega^2} \quad (16.70)$$

But from (16.60) and (16.65)–(16.67) the classical result for a pure (l, m) multipole is

$$\frac{M^{(c)2}}{U^2} = \frac{|M_z|^2}{U^2} = \frac{m^2}{\omega^2} \quad (16.71)$$

The reason for this difference lies in the quantum nature of the electromagnetic fields for a single photon. If the z component of angular momentum of a single photon is known precisely, the uncertainty principle requires that the other components be uncertain, with mean square values such that (16.70) holds. On the other hand, for a state of the radiation field containing many photons (the classical limit) the mean square values of the transverse components of angular momentum can be made negligible compared to the square of the z component. Then the classical limit (16.71) applies. For a (l, m) multipole field containing N photons it can be shown* that

$$\frac{[M^{(q)}(N)]^2}{[U(N)]^2} = \frac{N^2 m^2 + Nl(l+1) - m^2}{N^2 \omega^2} \quad (16.72)$$

This contains (16.70) and (16.71) as limiting cases.

The quantum-mechanical interpretation of the radiated angular momentum per photon for multipole fields contains the selection rules for multipole transitions between quantum states. A multipole transition of order (l, m) will connect an initial quantum state specified by total angular momentum J and z component M to a final quantum state with J' in the range $|J-l| \leq J' \leq J+l$ and $M' = M - m$. Or, alternatively, with two states (J, M) and (J', M') , possible multipole transitions have (l, m) such that $|J-J'| \leq l \leq J+J'$ and $m = M - M'$.

To complete the quantum-mechanical specification of a multipole transition it is necessary to state whether the parities of the initial and final states are the same or different. The parity of the initial state is equal to the product of the parities of the final state and the multipole field. To determine the parity of a multipole field we merely examine the behavior of the magnetic induction \mathbf{B}_{lm} under the parity transformation of inversion through the origin ($\mathbf{r} \rightarrow -\mathbf{r}$). One way of seeing that \mathbf{B}_{lm} specifies the parity of a multipole field is to recall that the interaction of a charged particle and the electromagnetic field is proportional to $(\mathbf{v} \cdot \mathbf{A})$. If \mathbf{B}_{lm} has a certain parity (even or odd) for a multipole transition, then

* C. Morette De Witt and J. H. D. Jensen, *Z. Naturforsch.*, **8a**, 267 (1953). Their treatment parallels ours closely, with our classical multipole coefficients $a_E(l, m)$ and $a_M(l, m)$ becoming quantum-mechanical photon annihilation operators (the complex conjugates, a_E^* and a_M^* , become hermitean conjugate creation operators).

the corresponding \mathbf{A}_{lm} will have the opposite parity, since the curl operation changes parity. Then, because \mathbf{v} is a polar vector with odd parity, the states connected by the interaction operator $(\mathbf{v} \cdot \mathbf{A})$ will differ in parity by the parity of the magnetic induction \mathbf{B}_{lm} .

For electric multipoles the magnetic induction is given by (16.57). The parity transformation ($\mathbf{r} \rightarrow -\mathbf{r}$) is equivalent to ($r \rightarrow r, \theta \rightarrow \pi - \theta, \phi \rightarrow \phi + \pi$) in spherical coordinates. The operator \mathbf{L} is invariant under inversion. Consequently the parity properties of \mathbf{B}_{lm} for electric multipoles are specified by the transformation of $Y_{lm}(\theta, \phi)$. From (3.53) and (3.50) it is evident that the parity of Y_{lm} is $(-1)^l$. Thus we see that the parity of fields of an electric multipole of order (l, m) is $(-1)^l$. Specifically, the magnetic induction \mathbf{B}_{lm} has parity $(-1)^l$, while the electric field \mathbf{E}_{lm} has parity $(-1)^{l+1}$, since $\mathbf{E}_{lm} = i\nabla \times \mathbf{B}_{lm}/k$.

For a magnetic multipole of order (l, m) the parity is $(-1)^{l+1}$. In this case the electric field \mathbf{E}_{lm} is of the same form as \mathbf{B}_{lm} for electric multipoles. Hence the parities of the fields are just opposite to those of an electric multipole of the same order.

Correlating the parity changes and angular-momentum changes in quantum transitions, we see that only certain combinations of multipole transitions can occur. For example, if the states have $J = \frac{1}{2}$ and $J' = \frac{3}{2}$, the allowed multipole orders are $l = 1, 2$. If the parities of the two states are the same, we see that parity conservation restricts the possibilities, so that only magnetic dipole and electric quadrupole transitions occur. If the states differ in parity, then electric dipole and magnetic quadrupole radiation can be emitted or absorbed.

16.4 Angular Distribution of Multipole Radiation

For a general localized source distribution the fields in the radiation zone are given by the superposition,

$$\begin{aligned} \mathbf{B} &\rightarrow \frac{e^{ikr - i\omega t}}{kr} \sum_{l,m} (-i)^{l+1} [a_E(l, m) \mathbf{X}_{lm} + a_M(l, m) \mathbf{n} \times \mathbf{X}_{lm}] \\ \mathbf{E} &\rightarrow \mathbf{B} \times \mathbf{n} \end{aligned} \quad (16.73)$$

The coefficients $a_E(l, m)$ and $a_M(l, m)$ will be related to the properties of the source in the next section. The time-averaged power radiated per unit solid angle is

$$\frac{dP}{d\Omega} = \frac{c}{8\pi k^2} \left| \sum_{l,m} (-i)^{l+1} [a_E(l, m) \mathbf{X}_{lm} \times \mathbf{n} + a_M(l, m) \mathbf{X}_{lm}] \right|^2 \quad (16.74)$$

Within the absolute value signs the polarization of the radiation is specified by the directions of the vectors. We note that electric and magnetic multipoles of a given (l, m) have the same angular dependence, but have polarizations at right

angles to one another. Thus the multipole order can be determined by measurement of the angular distribution of radiated power, but the character of the radiation (electric or magnetic) can be determined only by a polarization measurement.

For a pure multipole of order (l, m) the angular distribution (16.74) reduces to a single term,

$$\frac{dP(l, m)}{d\Omega} = \frac{c}{8\pi k^2} |a(l, m)|^2 |\mathbf{X}_{lm}|^2 \quad (16.75)$$

From definition (16.43) of \mathbf{X}_{lm} and properties (16.28), this can be transformed into the explicit form:

$$\frac{dP(l, m)}{d\Omega} = \frac{c}{8\pi k^2 l(l+1)} \left\{ \frac{1}{2}(l-m)(l+m+1) |Y_{l,m+1}|^2 + \frac{1}{2}(l+m)(l-m+1) |Y_{l,m-1}|^2 + m^2 |Y_{lm}|^2 \right\} \quad (16.76)$$

The table lists some of the simpler angular distributions.

$$|\mathbf{X}_{lm}(\theta, \phi)|^2$$

l	m		
	0	± 1	± 2
1 Dipole	$\frac{3}{8\pi} \sin^2 \theta$	$\frac{3}{16\pi} (1 + \cos^2 \theta)$	
2 Quadrupole	$\frac{15}{8\pi} \sin^2 \theta \cos^2 \theta$	$\frac{5}{16\pi} (1 - 3 \cos^2 \theta + 4 \cos^4 \theta)$	$\frac{5}{16\pi} (1 - \cos^4 \theta)$

The dipole distributions are seen to be those of a dipole oscillating parallel to the z axis ($m=0$) and of two dipoles, one along the x axis and one along the y axis, 90° out of phase ($m=\pm 1$). The dipole and quadrupole angular distributions are plotted as polar intensity diagrams in Fig. 16.1. These are representative of $l=1$ and $l=2$ multipole angular distributions, although a general multipole distribution of order l will involve a coherent superposition of the $(2l+1)$ amplitudes for different m , as shown in (16.74).

It can be shown by means of (3.69) that the absolute squares of the vector spherical harmonics obey the sum rule,

$$\sum_{m=-l}^l |\mathbf{X}_{lm}(\theta, \phi)|^2 = \frac{2l+1}{4\pi} \quad (16.77)$$

Hence the radiation distribution will be isotropic from a source which consists of a set of multipoles of order l , with coefficients $a(l, m)$ independent of m , superposed incoherently. This situation usually prevails in atomic and nuclear radiative transitions unless the initial state has been prepared in a special way.

The total power radiated by a pure multipole of order (l, m) is given by the

Fig. 16.1 Dipole and quadrupole radiation patterns for pure (l, m) multipoles.

integral of (16.75) over all angles. Since the \mathbf{X}_{lm} are normalized to unity, the power radiated is

$$P(l, m) = \frac{c}{8\pi k^2} |a(l, m)|^2 \quad (16.78)$$

For a general source the angular distribution is given by the coherent sum (16.74). On integration over angles it is easy to show that the interference terms do not contribute. Hence the total power radiated is just an incoherent sum of contributions from the different multipoles:

$$P = \frac{c}{8\pi k^2} \sum_{l,m} [|a_E(l, m)|^2 + |a_M(l, m)|^2] \quad (16.79)$$

16.5 Sources of Multipole Radiation, Multipole Moments

Having discussed the properties of multipole fields, the radiation patterns, and the angular momentum and energy carried off, we now turn to the connection of the fields with the sources that generate them. We assume that there exist localized well-behaved distributions of charge $\rho(\mathbf{x}, t)$, current $\mathbf{J}(\mathbf{x}, t)$, and intrinsic magnetization $\mathcal{M}(\mathbf{x}, t)$. Furthermore, we assume that the time dependence can be analyzed into its Fourier components, and we consider only harmonically varying sources,

$$\rho(\mathbf{x})e^{-i\omega t}, \quad \mathbf{J}(\mathbf{x})e^{-i\omega t}, \quad \mathcal{M}(\mathbf{x})e^{-i\omega t} \quad (16.80)$$

where it is understood that we take the real part of such complex quantities. A more general time dependence can be obtained by linear superposition (see also Problem 9.1).

The Maxwell equations for \mathbf{E} and \mathbf{B} are

$$\left. \begin{aligned} \nabla \cdot \mathbf{B} &= 0, & \nabla \times \mathbf{E} - ik\mathbf{B} &= 0 \\ \nabla \cdot \mathbf{E} &= 4\pi\rho, & \nabla \times \mathbf{B} + ik\mathbf{E} &= \frac{4\pi}{c}(\mathbf{J} + c\nabla \times \mathcal{M}) \end{aligned} \right\} \quad (16.81)$$

with the continuity equation,

$$i\omega\rho = \nabla \cdot \mathbf{J} \quad (16.82)$$

It is convenient to deal with divergenceless fields. Accordingly, we use as field variables, \mathbf{B} and

$$\mathbf{E}' = \mathbf{E} + \frac{4\pi i}{\omega} \mathbf{J} \quad (16.83)$$

In the region outside the sources, \mathbf{E}' reduces to \mathbf{E} . In terms of these fields the

Maxwell equations read

$$\left. \begin{aligned} \nabla \cdot \mathbf{B} &= 0, & \nabla \times \mathbf{E}' - ik\mathbf{B} &= \frac{4\pi i}{\omega} \nabla \times \mathbf{J} \\ \nabla \cdot \mathbf{E}' &= 0, & \nabla \times \mathbf{B} + ik\mathbf{E}' &= 4\pi \nabla \times \mathcal{M} \end{aligned} \right\} \quad (16.84)$$

The curl equations can be combined to give the inhomogeneous Helmholtz wave equations,

$$(\nabla^2 + k^2)\mathbf{B} = -\frac{4\pi}{c} \nabla \times (\mathbf{J} + c \nabla \times \mathcal{M}) \quad (16.85)$$

and

$$(\nabla^2 + k^2)\mathbf{E}' = -4\pi ik \nabla \times \left(\mathcal{M} + \frac{1}{ck^2} \nabla \times \mathbf{J} \right)$$

These wave equations, together with $\nabla \cdot \mathbf{B} = 0$, $\nabla \cdot \mathbf{E}' = 0$, and the curl equations giving \mathbf{E}' in terms of \mathbf{B} or vice versa, are the counterparts of (16.32) and (16.33) when sources are present.

Since the multipole coefficients in (16.46) are determined according to (16.47) from the scalars $\mathbf{r} \cdot \mathbf{B}$ and $\mathbf{r} \cdot \mathbf{E}'$, it is sufficient to consider wave equations for them, rather than the vector fields \mathbf{E}' and \mathbf{B} . From (16.34), (16.85) and the vector relation, $\mathbf{r} \cdot (\nabla \times \mathbf{A}) = (\mathbf{r} \times \nabla) \cdot \mathbf{A} = -i\mathbf{L} \cdot \mathbf{A}$ for any vector field \mathbf{A} , we find the inhomogeneous wave equations,

$$\left. \begin{aligned} (\nabla^2 + k^2)\mathbf{r} \cdot \mathbf{B} &= -\frac{4\pi i}{c} \mathbf{L} \cdot (\mathbf{J} + c \nabla \times \mathcal{M}) \\ (\nabla^2 + k^2)\mathbf{r} \cdot \mathbf{E}' &= 4\pi k \mathbf{L} \cdot \left(\mathcal{M} + \frac{1}{ck^2} \nabla \times \mathbf{J} \right) \end{aligned} \right\} \quad (16.86)$$

The solutions of these scalar wave equations follow directly from the development in Section 6.6. With the boundary condition of outgoing waves at infinity, we have

$$\left. \begin{aligned} \mathbf{r} \cdot \mathbf{B}(\mathbf{x}) &= \frac{i}{c} \int \frac{e^{ik|\mathbf{x}-\mathbf{x}'|}}{|\mathbf{x}-\mathbf{x}'|} \mathbf{L}' \cdot [\mathbf{J}(\mathbf{x}') + c \nabla' \times \mathcal{M}(\mathbf{x}')] d^3x' \\ \mathbf{r} \cdot \mathbf{E}'(\mathbf{x}) &= -k \int \frac{e^{ik|\mathbf{x}-\mathbf{x}'|}}{|\mathbf{x}-\mathbf{x}'|} \mathbf{L}' \cdot \left[\mathcal{M}(\mathbf{x}') + \frac{1}{ck^2} \nabla' \times \mathbf{J}(\mathbf{x}') \right] d^3x' \end{aligned} \right\} \quad (16.87)$$

To evaluate the multipole coefficients by means of (16.47), we first observe that the requirement of outgoing waves at infinity makes $A_l^{(2)} = 0$ in (16.37). Thus we choose $f_l(kr) = g_l(kr) = h_l^{(1)}(kr)$ in (16.46) as the representation of \mathbf{E} and \mathbf{B} outside the sources. Next we consider the spherical wave representation (16.22) for the Green function in (16.87) and assume that the point \mathbf{x} is outside a spherical surface completely enclosing the sources. Then in the integrations in (16.87), $r_< = r'$, $r_> = r$. The spherical wave projection needed for (16.47) is

$$\int d\Omega Y_{lm}^*(\theta, \phi) \frac{e^{ik|\mathbf{x}-\mathbf{x}'|}}{|\mathbf{x}-\mathbf{x}'|} = 4\pi ik h_l^{(1)}(kr) j_l(kr') Y_{lm}^*(\theta', \phi') \quad (16.88)$$

By means of this projection we see that $a_M(l, m)$ and $a_E(l, m)$ are given in terms of the integrands in (16.87) by

$$\begin{aligned} a_E(l, m) &= \frac{4\pi k^3}{\sqrt{l(l+1)}} \int j_l(kr) Y_{lm}^* \mathbf{L} \cdot \left(\mathcal{M} + \frac{1}{ck^2} \nabla \times \mathbf{J} \right) d^3x \\ a_M(l, m) &= \frac{-4\pi k^2}{\sqrt{l(l+1)}} \int j_l(kr) Y_{lm}^* \mathbf{L} \cdot \left(\frac{\mathbf{J}}{c} + \nabla \times \mathcal{M} \right) d^3x \end{aligned} \quad (16.89)$$

The expressions in (16.89) give the strengths of the various multipole fields outside the source in terms of integrals over the source densities \mathbf{J} and \mathcal{M} . They can be transformed into more useful forms by means of the following identities: Let $\mathbf{A}(\mathbf{x})$ be any well-behaved vector field. Then

$$\begin{aligned} \mathbf{L} \cdot \mathbf{A} &= i\nabla \cdot (\mathbf{r} \times \mathbf{A}) \\ \mathbf{L} \cdot (\nabla \times \mathbf{A}) &= i\nabla^2(\mathbf{r} \cdot \mathbf{A}) - \frac{i}{r} \frac{\partial}{\partial r} (r^2 \nabla \cdot \mathbf{A}) \end{aligned} \quad (16.90)$$

These follow from the definition (16.25) of \mathbf{L} and simple vector identities. With $\mathbf{A} = \mathcal{M}$ in the first equation and $\mathbf{A} = \mathbf{J}$ in the second, the integral for $a_E(l, m)$ in (16.89) becomes

$$a_E(l, m) = -\frac{4\pi k^3}{\sqrt{l(l+1)}} \int j_l(kr) Y_{lm}^* \left[\nabla \cdot (\mathbf{r} \times \mathcal{M}) + \frac{1}{ck^2} \nabla^2(\mathbf{r} \cdot \mathbf{J}) - \frac{i}{k} \frac{1}{r} \frac{\partial}{\partial r} (r^2 \rho) \right] d^3x$$

where we have used (16.82) to express $\nabla \cdot \mathbf{J}$ in terms of ρ . Use of Green's theorem on the second term replaces ∇^2 by $-k^2$, while a radial integration by parts on the third term casts the radial derivative over onto the spherical Bessel function. The result for the *electric multipole coefficient* is

$$a_E(l, m) = \frac{4\pi k^2}{i\sqrt{l(l+1)}} \int Y_{lm}^* \left\{ \rho \frac{\partial}{\partial r} [r j_l(kr)] + \frac{ik}{c} (\mathbf{r} \cdot \mathbf{J}) j_l(kr) - ik \nabla \cdot (\mathbf{r} \times \mathcal{M}) j_l(kr) \right\} d^3x \quad (16.91)$$

The analogous manipulation with the second equation in (16.89) leads to the *magnetic multipole coefficient*,

$$a_M(l, m) = \frac{4\pi k^2}{i\sqrt{l(l+1)}} \int Y_{lm}^* \left\{ \nabla \cdot \left(\frac{\mathbf{r} \times \mathbf{J}}{c} \right) j_l(kr) + \nabla \cdot \mathcal{M} \frac{\partial}{\partial r} [r j_l(kr)] - k^2 (\mathbf{r} \cdot \mathcal{M}) j_l(kr) \right\} d^3x \quad (16.92)$$

These results are exact expressions, valid for arbitrary frequency and source size.

For many applications in atomic and nuclear physics the source dimensions are very small compared to a wavelength ($kr_{\max} \ll 1$). Then the multipole coefficients can be simplified considerably. The small argument limit (16.12) can be used for the spherical Bessel functions. Keeping only the lowest powers in kr for terms involving ρ or \mathbf{J} and \mathcal{M} , we find the approximate electric multipole

coefficient,

$$a_E(l, m) \approx \frac{4\pi k^{l+2}}{i(2l+1)!!} \left(\frac{l+1}{l}\right)^{1/2} (Q_{lm} + Q'_{lm}) \quad (16.93)$$

where the multipole moments are

$$\left. \begin{aligned} Q_{lm} &= \int r^l Y_{lm}^* \rho \, d^3x \\ Q'_{lm} &= \frac{-ik}{l+1} \int r^l Y_{lm}^* \nabla \cdot (\mathbf{r} \times \mathcal{M}) \, d^3x \end{aligned} \right\} \quad (16.94)$$

The moment Q_{lm} is seen to be the same in form as the electrostatic multipole moment q_{lm} (4.3). The moment Q'_{lm} is an induced electric multipole moment due to the magnetization. It is generally at least a factor kr smaller than the normal moment Q_{lm} . For the magnetic multipole coefficient $a_M(l, m)$ the corresponding long-wavelength approximation is

$$a_M(l, m) \approx \frac{4\pi i k^{l+2}}{(2l+1)!!} \left(\frac{l+1}{l}\right)^{1/2} (M_{lm} + M'_{lm}) \quad (16.95)$$

where the magnetic multipole moments are

$$\left. \begin{aligned} M_{lm} &= -\frac{1}{l+1} \int r^l Y_{lm}^* \nabla \cdot \left(\frac{\mathbf{r} \times \mathbf{J}}{c}\right) \, d^3x \\ M'_{lm} &= -\int r^l Y_{lm}^* \nabla \cdot \mathcal{M} \, d^3x \end{aligned} \right\} \quad (16.96)$$

In contrast to the electric multipole moments Q_{lm} and Q'_{lm} , for a system with intrinsic magnetization the magnetic moments M_{lm} and M'_{lm} are generally of the same order of magnitude.

In the long-wavelength limit we see clearly the fact that electric multipole fields are related to the electric-charge density ρ , while the magnetic multipole fields are determined by the magnetic-moment densities, $(\mathbf{r} \times \mathbf{J})/2c$ and \mathcal{M} .

16.6 Multipole Radiation in Atomic and Nuclear Systems

Although a full discussion involves a proper quantum-mechanical treatment of the states involved,* the essential features of multipole radiation in atoms and

* See Blatt and Weisskopf, pp. 597–599, for the quantum-mechanical definitions of the multipole moments. Beware of factors of 2 between our moments and theirs, due to their definitions, (3.1) and (3.2) on p. 590, of the source densities, as compared to our (16.80). See Problem 9.1 concerning the connection between the factorized forms in (16.80) and classical sources $\rho(\mathbf{x}, t)$, etc.

nuclei can be presented with simple arguments. From (16.78) and the multipole coefficients (16.93) and (16.95), the total power radiated by a multipole of order (l, m) is

$$\left. \begin{aligned} P_E(l, m) &= \frac{2\pi c}{[(2l+1)!!]^2} \left(\frac{l+1}{l}\right) k^{2l+2} |Q_{lm} + Q'_{lm}|^2 \\ P_M(l, m) &= \frac{2\pi c}{[(2l+1)!!]^2} \left(\frac{l+1}{l}\right) k^{2l+2} |M_{lm} + M'_{lm}|^2 \end{aligned} \right\} \quad (16.97)$$

In quantum-mechanical terms we are interested in the transition probability (reciprocal mean life), defined as the power divided by the energy of a photon:

$$\frac{1}{\tau} = \frac{P}{\hbar\omega} \quad (16.98)$$

Since we are concerned only with order-of-magnitude estimates, we make the following schematic model of the source. The oscillating charge density is assumed to be

$$\rho(\mathbf{x}) = \begin{cases} \frac{3e}{a^3} Y_{lm}(\theta, \phi), & r < a \\ 0, & r > a \end{cases} \quad (16.99)$$

Then an estimate of the electric multipole moment Q_{lm} is

$$Q_{lm} \approx \frac{3}{l+3} ea^l \quad (16.100)$$

independent of m . Similarly for the divergences of the magnetizations we assume the schematic form:

$$\nabla \cdot \mathcal{M} + \frac{1}{l+1} \nabla \cdot \left(\frac{\mathbf{r} \times \mathbf{J}}{c} \right) = \begin{cases} \frac{2g}{a^3} Y_{lm}(\theta, \phi) \left(\frac{e\hbar}{mcr} \right), & r < a \\ 0, & r > a \end{cases} \quad (16.101)$$

where g is the effective g factor for the magnetic moments of the particles in the atomic or nuclear system, and $e\hbar/mc$ is twice the Bohr magneton for those particles. Then an estimate of the sum of magnetic multipole moments is

$$M_{lm} + M'_{lm} \approx -\frac{2}{l+2} ea^l \left(\frac{g\hbar}{mca} \right) \quad (16.102)$$

From the definition of Q'_{lm} (16.94) we see that

$$Q'_{lm} \approx g \left(\frac{\hbar\omega}{mc^2} \right) Q_{lm} \quad (16.103)$$

Since the energies of radiative transitions in atoms and nuclei are always very small compared to the rest energies of the particles involved, Q'_{lm} is always completely negligible compared to Q_{lm} .

For electric multipole transitions of order l , estimate (16.100) leads to a transition probability (16.98):

$$\frac{1}{\tau_E(l)} \approx \left(\frac{e^2}{\hbar c}\right) \frac{2\pi}{[(2l+1)!!]^2} \left(\frac{l+1}{l}\right) \left(\frac{3}{l+3}\right)^2 (ka)^{2l} \omega \quad (16.104)$$

Apart from factors of the order of unity, the transition probability for magnetic multipoles is, according to (16.102),

$$\frac{1}{\tau_M(l)} \approx \left(\frac{g\hbar}{mca}\right)^2 \frac{1}{\tau_E(l)} \quad (16.105)$$

The presence of the factor $(ka)^{2l}$ in the transition probability (16.104) means that in the long-wavelength limit ($ka \ll 1$) the transition rate falls off rapidly with increasing multipole order, for a fixed frequency. Consequently in an atomic or nuclear transition the lowest nonvanishing multipole will generally be the only one of importance. The ratio of transition probabilities for successive orders of either electric or magnetic multipoles of the same frequency is

$$\frac{[\tau(l+1)]^{-1}}{[\tau(l)]^{-1}} \sim \frac{(ka)^2}{4l^2} \quad (16.106)$$

where we have omitted numerical factors of relative order $(1/l)$.

In atomic systems the electrons are the particles involved in the radiation process. The dimensions of the source can be taken as $a \approx (a_0/Z_{\text{eff}})$, where a_0 is the Bohr radius and Z_{eff} is an effective nuclear charge ($Z_{\text{eff}} \approx 1$ for transitions by valence electrons; $Z_{\text{eff}} \approx Z$ for X-ray transitions). To estimate ka we note that the atomic transition energy is generally of the order

$$\hbar\omega \lesssim Z_{\text{eff}}^2 \frac{e^2}{a_0} \quad (16.107)$$

so that

$$ka \lesssim \frac{Z_{\text{eff}}}{137} \quad (16.108)$$

From (16.106) we see that successive multipoles will be in the ratio $(Z_{\text{eff}}/137)^2$. The ratio of magnetic to electric multipole transition rates can be estimated from (16.105). The g factor is of the order of unity for electrons. With $a \approx a_0/Z_{\text{eff}}$ = $137(\hbar/mcZ_{\text{eff}})$, we see that the magnetic l th multipole rate is a factor $(Z_{\text{eff}}/137)^2$ smaller than the corresponding electric multipole rate. We conclude that in atoms electric dipole transitions will be most intense, with electric quadrupole and magnetic dipole transitions a factor $(Z_{\text{eff}}/137)^2$ weaker. Only for X-ray transitions in heavy elements is there the possibility of competition from other than the lowest-order electric multipole.

We now turn to the question of radiative transitions in atomic nuclei. Because nuclear radiative transition energies vary greatly (from ~ 10 keV to several MeV), the values of ka cover a wide range. This means that for a given multipole

order the transition probabilities (or mean lifetimes) will range over many powers of 10, depending on the energy release, overlapping the multipoles on either side. In spite of this, rough estimates (16.104) and (16.105) are useful in cataloging nuclear multipole transitions, because for a *fixed energy release* the estimates for different multipoles differ greatly.

Figure 16.2 shows a log-log plot of estimate (16.104) for lifetimes of electric multipole transitions, using e as the protonic charge and $a \approx 5.6 \times 10^{-13}$ cm. This is a nuclear radius appropriate to mass number $A \approx 100$. We see that, although the curves tend to converge at high energies, the lifetimes for different multipoles at the same energy differ by factors typically of order 10^5 . This means that the actual multipole moments in individual transitions can deviate widely

Fig. 16.2 Estimated lifetimes of excited nuclear states against emission of electric multipole radiation as a function of the photon energy for $l=1, 2, 3, 4$.

from our simple estimates without vitiating the usefulness of those estimates as a guide in assigning multipole orders. Experimentally,* the lifetime-energy diagram shows broad, but well-defined, bands lying in the vicinity of the straight lines in Fig. 16.2. There is a general tendency for estimate (16.104) to serve as a lower bound on the lifetime, corresponding to (16.100) being an upper bound on the multipole moment, but for certain so-called “enhanced” electric quadrupole transitions the lifetimes can be as much as 100 times shorter than shown in Fig. 16.2.

Magnetic and electric multipoles of the same order can be compared using (16.105). For nucleons the effective g factor is typically of the order of $g \sim 3$ because of their anomalous magnetic moments. Then, with the source size estimate $a \approx R = 1.2A^{1/3} \times 10^{-13}$ cm, we find

$$\frac{1}{\tau_M(l)} \approx \frac{0.3}{A^{2/3}} \frac{1}{\tau_E(l)} \quad (16.109)$$

The numerical factor ranges from 4×10^{-2} to 0.8×10^{-2} for $20 < A < 250$. We thus anticipate that for a given multipole order electric transitions will be 25–120 times as intense as magnetic transitions. For most multipoles this is generally true. But for $l=1$ there are special circumstances in nuclei (strongly attractive, charge-independent forces) which inhibit electric dipole transitions (at least at low energies). Then estimate (16.109) fails; magnetic dipole transitions are far commoner and just as intense as electric dipole transitions.

In Section 16.3 the parity and angular-momentum selection rules were discussed, and it was pointed out that in a transition between two quantum states a mixture of multipoles, such as magnetic l , $(l+2)$, . . . pole and electric $(l+1)$, $(l+3)$, . . . pole, could occur. In the long-wavelength limit we need consider only the lowest multipole of each type. Ratios (16.105) and (16.106) can be combined to yield the relative transition rates of electric $(l+1)$ pole to magnetic l pole (most commonly used for $l=1$),

$$\frac{[\tau_E(l+1)]^{-1}}{[\tau_M(l)]^{-1}} \approx \left(\frac{A^{1/3} E}{200l} \right)^2 \quad (16.110)$$

where E is the photon energy in MeV. For energetic transitions in heavy elements the electric quadrupole *amplitude* is ~ 5 per cent of the magnetic dipole amplitude. If, as actually occurs in the rare earth and transuranic nuclei, there is an enhancement of the effective quadrupole moment by a factor of 10, the electric quadrupole transition competes favorably with the magnetic dipole transition.

For a mixture of magnetic $(l+1)$ pole and electric l pole, the ratio of transition

* See Figures 1 and 2 of the article by M. Goldhaber and J. Weneser, *Annual Review of Nuclear Science*, Vol. 5, ed., J. G. Beckerley, Annual Reviews, Stanford (1955), p. 1–24.

rates is

$$\frac{[\tau_M(l+1)]^{-1}}{[\tau_E(l)]^{-1}} \simeq \left(\frac{E}{600l}\right)^2 \quad (16.111)$$

Even for energetic transitions, a magnetic $(l+1)$ pole never comes close to competing with an electric l pole.

16.7 Radiation from a Linear, Center-Fed Antenna

As an illustration of the use of a multipole expansion for a source whose dimensions are comparable to a wavelength, we consider the radiation from a thin, linear, center-fed antenna, as shown in Fig. 16.3. We have already given in Chapter 9 a direct solution for the fields when the current distribution is taken to be sinusoidal. This will serve as a basis of comparison to test the convergence of the multipole expansion. We assume the antenna to lie along the z axis from $-(d/2) \leq z \leq (d/2)$, and to have a small gap at its center so that it can be suitably excited. The current along the antenna vanishes at the end points and is an even function of z . For the moment we will not specify it more than to write

$$I(z, t) = I(|z|)e^{-i\omega t}, \quad I\left(\frac{d}{2}\right) = 0 \quad (16.112)$$

Since the current flows radially, $(\mathbf{r} \times \mathbf{J}) = 0$. Furthermore there is no intrinsic magnetization. Consequently all magnetic multipole coefficients $a_M(l, m)$ vanish.

Fig. 16.3 Linear, center-fed antenna.

To calculate the electric multipole coefficient $a_E(l, m)$ (16.91) we need expressions for the charge and current densities. The current density \mathbf{J} is a radial current, confined to the z axis. In spherical coordinates this can be written for $r < (d/2)$

$$\mathbf{J}(\mathbf{x}) = \epsilon_r \frac{I(r)}{2\pi r^2} [\delta(\cos \theta - 1) - \delta(\cos \theta + 1)] \quad (16.113)$$

where the delta functions cause the current to flow only upwards (or downwards) along the z axis. From the continuity equation (16.82) we find the charge density,

$$\rho(\mathbf{x}) = \frac{1}{i\omega} \frac{dI(r)}{dr} \left[\frac{\delta(\cos \theta - 1) - \delta(\cos \theta + 1)}{2\pi r^2} \right] \quad (16.114)$$

These expressions for \mathbf{J} and ρ can be inserted into (16.91) to give

$$a_E(l, m) = \frac{2k^2}{\sqrt{l(l+1)}} \int_0^{d/2} dr \left\{ \frac{k}{c} r j_l(kr) I(r) - \frac{1}{\omega} \frac{dI}{dr} \frac{d}{dr} [r j_l(kr)] \right\} \\ \times \int d\Omega Y_{lm}^* [\delta(\cos \theta - 1) - \delta(\cos \theta + 1)] \quad (16.115)$$

The integral over angles is

$$\int d\Omega = 2\pi \delta_{m,0} [Y_{l0}(0) - Y_{l0}(\pi)] \quad (16.116)$$

showing that only $m=0$ multipoles occur. This is obvious from the cylindrical symmetry of the antenna. The Legendre polynomials are even (odd) about $\theta = \pi/2$ for l even (odd). Hence, the only nonvanishing multipoles have l odd. Then the angular integral has the value,

$$\int d\Omega = \sqrt{4\pi(2l+1)}, \quad l \text{ odd}, m=0 \quad (16.117)$$

With slight manipulation (16.115) can be written

$$a_E(l, 0) = \frac{2k}{c} \left[\frac{4\pi(2l+1)}{l(l+1)} \right]^{1/2} \int_0^{d/2} \left\{ -\frac{d}{dr} [r j_l(kr) \frac{dI}{dr}] + r j_l(kr) \left(\frac{d^2 I}{dr^2} + k^2 I \right) \right\} dr \quad (16.118)$$

To evaluate (16.118) we must specify the current $I(z)$ along the antenna. If no radiation occurred, the sinusoidal variation in time at frequency ω would imply a sinusoidal variation in space with wave number $k = \omega/c$. But as has been discussed in Section 9.4(b), the emission of radiation modifies the current distribution unless the antenna is infinitely thin. The correct current $I(z)$ can only be found by solving a complicated boundary-value problem. Since our purpose here is to compare a multipole expansion with a closed form of solution for a known current distribution, we make the same assumption about $I(z)$ as in Section 9.4(a), namely,

$$I(z) = I \sin \left(\frac{kd}{2} - k|z| \right) \quad (16.119)$$

where I is the peak current, and the phase is so chosen that the current vanishes at the ends of the antenna. With a sinusoidal current the second part of the integrand in (16.118) vanishes. The first part is a perfect differential. Consequently we immediately obtain, with $I(z)$ from (16.119),

$$a_E(l, 0) = \frac{4I \left[\frac{4\pi(2l+1)}{l(l+1)} \right]^{1/2} \left[\left(\frac{kd}{2} \right)^2 j_l \left(\frac{kd}{2} \right) \right]}{cd}, \quad l \text{ odd} \quad (16.120)$$

Since we wish to test the multipole expansion when the source dimensions are comparable to a wavelength, we consider the special cases of a half-wave antenna ($kd = \pi$) and a full-wave antenna ($kd = 2\pi$). For these two values of kd the $l = 1$ coefficient is tabulated, along with the relative values for $l = 3, 5$. From the table it is evident that (a) the coefficients decrease rapidly in magnitude as l increases, and (b) higher l coefficients are more important the larger the source dimensions. But even for the full-wave antenna it is probably adequate to keep only $l = 1$ and $l = 3$ in the angular distribution and certainly adequate for the total power (which involves the squares of the coefficients).

kd	$a_E(1, 0)$	$a_E(3, 0)/a_E(1, 0)$	$a_E(5, 0)/a_E(1, 0)$
π	$4\sqrt{6\pi} \frac{I}{cd}$	4.95×10^{-2}	1.02×10^{-3}
2π	$4\pi\sqrt{6\pi} \frac{I}{cd}$	0.325	3.09×10^{-2}

With only dipole and octupole terms in the angular distribution we find that the power radiated per unit solid angle (16.74) is

$$\frac{dP}{d\Omega} = \frac{c |a_E(1, 0)|^2}{16\pi k^2} \left| \mathbf{L}Y_{1,0} - \frac{a_E(3, 0)}{\sqrt{6} a_E(1, 0)} \mathbf{L}Y_{3,0} \right|^2 \quad (16.121)$$

The various factors in the absolute square are

$$\left. \begin{aligned} |\mathbf{L}Y_{1,0}|^2 &= \frac{3}{4\pi} \sin^2 \theta \\ |\mathbf{L}Y_{3,0}|^2 &= \frac{63}{16\pi} \sin^2 \theta (5 \cos^2 \theta - 1)^2 \\ (\mathbf{L}Y_{1,0})^* \cdot (\mathbf{L}Y_{3,0}) &= \frac{3\sqrt{21}}{8\pi} \sin^2 \theta (5 \cos^2 \theta - 1) \end{aligned} \right\} \quad (16.122)$$

With these angular factors (16.121) becomes

$$\frac{dP}{d\Omega} = \lambda \frac{12I^2}{\pi^2 c} \left(\frac{3}{8\pi} \sin^2 \theta \right) \left| 1 - \sqrt{\frac{7}{8}} \frac{a_E(3, 0)}{a_E(1, 0)} (5 \cos^2 \theta - 1) \right|^2 \quad (16.123)$$

where the factor λ is equal to 1 for the half-wave antenna and $(\pi^2/4)$ for the full wave. The coefficient of $(5 \cos^2 \theta - 1)$ in (16.123) is 0.0463 and 0.304 for the half-wave and full-wave antenna, respectively.

From Chapter 9 the exact angular distributions (for sinusoidal driving currents) are

$$\frac{dP}{d\Omega} = \frac{I^2}{2\pi c} \begin{cases} \frac{\cos^2\left(\frac{\pi}{2} \cos \theta\right)}{\sin^2 \theta}, & kd = \pi \\ \frac{\cos^4\left(\frac{\pi}{2} \cos \theta\right)}{4 \sin^2 \theta}, & kd = 2\pi \end{cases} \quad (16.124)$$

A numerical comparison of the exact and approximate angular distributions is shown in Fig. 16.4. The solid curves are the exact results, the dashed curves the

Fig. 16.4 Comparison of exact radiation patterns (solid curves) for half-wave ($kd = \pi$) and full-wave ($kd = 2\pi$) center-fed antennas with two-term multipole expansions (dashed curves). For the half-wave pattern, the dipole approximation (dotted curve) is also shown. The agreement between the exact and two-term multipole results is excellent, especially for $kd = \pi$.

two-term multipole expansions. For the half-wave case (Fig. 16.4a) the simple dipole result [first term in (16.123)] is also shown as a dotted curve. The two-term multipole expansion is almost indistinguishable from the exact result for $kd = \pi$. Even the lowest-order approximation is not very far off in this case. For the full-wave antenna (Fig. 16.4b) the dipole approximation is evidently quite poor. But the two-term multipole expansion is reasonably good, differing by less than 5 per cent in the region of appreciable radiation.

The total power radiated is, according to (16.79),

$$P = \frac{c}{8\pi k^2} \sum_{l \text{ odd}} |a_E(l, 0)|^2 \quad (16.125)$$

For the half-wave antenna the coefficients in the table on p. 765 show that the power radiated is a factor 1.00245 times larger than the simple dipole result, $(12I^2/\pi^2 c)$. For the full-wave antenna, the power is a factor 1.114 times larger than the dipole form $(3I^2/c)$.

16.8 Spherical Wave Expansion of a Vector Plane Wave

In discussing the scattering or absorption of electromagnetic radiation by spherical objects, or localized systems in general, it is useful to have an expansion of a plane electromagnetic wave in spherical waves.

For a scalar field $\psi(\mathbf{x})$ satisfying the wave equation the necessary expansion can be obtained by using the orthogonality properties of the basic spherical solutions $j_l(kr)Y_{lm}(\theta, \phi)$. An alternative derivation makes use of the spherical wave expansion (16.22) of the Green function $(e^{ikR}/4\pi R)$. We let $|\mathbf{x}'| \rightarrow \infty$ on both sides of (16.22). Then we can put $|\mathbf{x} - \mathbf{x}'| \approx r' - \mathbf{n} \cdot \mathbf{x}$ on the left-hand side, where \mathbf{n} is a unit vector in the direction of \mathbf{x}' . On the right side $r_+ = r'$ and $r_- = r$. Furthermore we can use the asymptotic form (16.13) for $h_l^{(1)}(kr')$. Then we find

$$\frac{e^{ikr'}}{4\pi r'} e^{-ik\mathbf{n} \cdot \mathbf{x}} = ik \frac{e^{ikr'}}{kr'} \sum_{l,m} (-i)^{l+1} j_l(kr) Y_{lm}^*(\theta', \phi') Y_{lm}(\theta, \phi) \quad (16.126)$$

Canceling the factor $e^{ikr'}/r'$ on either side and taking the complex conjugate, we have the expansion of a plane wave,

$$e^{ik \cdot \mathbf{x}} = 4\pi \sum_{l=0}^{\infty} i^l j_l(kr) \sum_{m=-l}^l Y_{lm}^*(\theta, \phi) Y_{lm}(\theta', \phi') \quad (16.127)$$

where \mathbf{k} is the wave vector with spherical coordinates k, θ', ϕ' . The addition theorem (3.62) can be used to put this in a more compact form,

$$e^{ik \cdot \mathbf{x}} = \sum_{l=0}^{\infty} i^l (2l+1) j_l(kr) P_l(\cos \gamma) \quad (16.128)$$

where γ is the angle between \mathbf{k} and \mathbf{x} . With (3.57) for $P_l \cos(\gamma)$, this can also be written as

$$e^{i\mathbf{k}\cdot\mathbf{x}} = \sum_{l=0}^{\infty} i^l \sqrt{4\pi(2l+1)} j_l(kr) Y_{l,0}(\gamma) \quad (16.129)$$

We now wish to make an equivalent expansion for a circularly polarized plane wave with helicity \pm incident along the z axis,

$$\left. \begin{aligned} \mathbf{E}(\mathbf{x}) &= (\boldsymbol{\epsilon}_1 \pm i\boldsymbol{\epsilon}_2) e^{ikz} \\ \mathbf{B}(\mathbf{x}) &= \boldsymbol{\epsilon}_3 \times \mathbf{E} = \mp i\mathbf{E} \end{aligned} \right\} \quad (16.130)$$

Since the plane wave is finite everywhere, we can write its multipole expansion (16.46) involving only the regular radial functions $j_l(kr)$:

$$\left. \begin{aligned} \mathbf{E}(\mathbf{x}) &= \sum_{l,m} \left[a_{\pm}(l, m) j_l(kr) \mathbf{X}_{lm} + \frac{i}{k} b_{\pm}(l, m) \nabla \times j_l(kr) \mathbf{X}_{lm} \right] \\ \mathbf{B}(\mathbf{x}) &= \sum_{l,m} \left[\frac{-i}{k} a_{\pm}(l, m) \nabla \times j_l(kr) \mathbf{X}_{lm} + b_{\pm}(l, m) j_l(kr) \mathbf{X}_{lm} \right] \end{aligned} \right\} \quad (16.131)$$

To determine the coefficients $a_{\pm}(l, m)$ and $b_{\pm}(l, m)$ we utilize the orthogonality properties of the vector spherical harmonics \mathbf{X}_{lm} . For reference purposes we summarize the basic relation (16.44), as well as some other useful relations:

$$\left. \begin{aligned} \int [f_l(r) \mathbf{X}_{l'm'}]^* \cdot [g_l(r) \mathbf{X}_{lm}] d\Omega &= f_l^* g_l \delta_{ll'} \delta_{mm'} \\ \int [f_l(r) \mathbf{X}_{l'm'}]^* \cdot [\nabla \times g_l(r) \mathbf{X}_{lm}] d\Omega &= 0 \\ \frac{1}{k^2} \int [\nabla \times f_l(r) \mathbf{X}_{l'm'}]^* \cdot [\nabla \times g_l(r) \mathbf{X}_{lm}] d\Omega \\ &= \delta_{ll'} \delta_{mm'} \left\{ f_l^* g_l + \frac{1}{k^2 r^2} \frac{\partial}{\partial r} \left[r f_l^* \frac{\partial}{\partial r} (r g_l) \right] \right\} \end{aligned} \right\} \quad (16.132)$$

In these relations $f_l(r)$ and $g_l(r)$ are linear combinations of spherical Bessel functions, satisfying (16.5). The second and third relations can be proved using the operator identity (16.49), the representation

$$\nabla = \frac{\mathbf{r}}{r} \frac{\partial}{\partial r} - \frac{i}{r^2} \mathbf{r} \times \mathbf{L}$$

for the gradient operator, and the radial differential equation (16.5).

To determine the coefficients $a_{\pm}(l, m)$ and $b_{\pm}(l, m)$ we take the scalar product of both sides of (16.131) with \mathbf{X}_{lm}^* and integrate over angles. Then with the first and second orthogonality relations in (16.132) we obtain

$$a_{\pm}(l, m) j_l(kr) = \int \mathbf{X}_{lm}^* \cdot \mathbf{E}(\mathbf{x}) d\Omega \quad (16.133)$$

and

$$b_{\pm}(l, m)j_l(kr) = \int \mathbf{X}_{lm}^* \cdot \mathbf{B}(\mathbf{x}) d\Omega \quad (16.134)$$

With (16.130) for the electric field, (16.133) becomes

$$a_{\pm}(l, m)j_l(kr) = \int \frac{(L_{\mp} Y_{lm})^*}{\sqrt{l(l+1)}} e^{ikz} d\Omega \quad (16.135)$$

where the operators L_{\pm} are defined by (16.26), and the results of their operating by (16.28). Thus we obtain

$$a_{\pm}(l, m)j_l(kr) = \frac{\sqrt{(l \pm m)(l \mp m + 1)}}{\sqrt{l(l+1)}} \int Y_{l, m \mp 1}^* e^{ikz} d\Omega \quad (16.136)$$

If expansion (16.129) for e^{ikz} is inserted, the orthogonality of the Y_m 's evidently leads to the result,

$$a_{\pm}(l, m) = i^l \sqrt{4\pi(2l+1)} \delta_{m, \pm 1} \quad (16.137)$$

From (16.134) and (16.130) it is clear that

$$b_{\pm}(l, m) = \mp i a_{\pm}(l, m) \quad (16.138)$$

Then the multipole expansion of the plane wave (16.130) is

$$\begin{aligned} \mathbf{E}(\mathbf{x}) &= \sum_{l=1}^{\infty} i^l \sqrt{4\pi(2l+1)} \left[j_l(kr) \mathbf{X}_{l, \pm 1} \pm \frac{1}{k} \nabla \times j_l(kr) \mathbf{X}_{l, \pm 1} \right] \\ \mathbf{B}(\mathbf{x}) &= \sum_{l=1}^{\infty} i^l \sqrt{4\pi(2l+1)} \left[\frac{-i}{k} \nabla \times j_l(kr) \mathbf{X}_{l, \pm 1} \mp j_l(kr) \mathbf{X}_{l, \pm 1} \right] \end{aligned} \quad (16.139)$$

For such a circularly polarized wave the m values of $m = \pm 1$ have the obvious interpretation of ± 1 unit of angular momentum per photon parallel to the propagation direction. This has already been established in Problems 7.20 and 7.21.

16.9 Scattering of Electromagnetic Waves by a Sphere

If a plane wave of electromagnetic radiation is incident on a spherical obstacle, as indicated schematically in Fig. 16.5, it is scattered, so that far away from the scatterer the fields are represented by a plane wave plus outgoing spherical waves. There may be absorption by the obstacle as well as scattering. Then the total energy flow away from the obstacle will be less than the total energy flow towards it, the difference being absorbed. We will ultimately consider the simple example of scattering by a sphere of radius a and infinite conductivity, but will for a time keep the problem more general.

Fig. 16.5 Scattering of radiation by a localized object.

The fields outside the sphere can be written as a sum of incident and scattered waves:

$$\left. \begin{aligned} \mathbf{E}(\mathbf{x}) &= \mathbf{E}_{\text{inc}} + \mathbf{E}_{\text{sc}} \\ \mathbf{B}(\mathbf{x}) &= \mathbf{B}_{\text{inc}} + \mathbf{B}_{\text{sc}} \end{aligned} \right\} \quad (16.140)$$

where \mathbf{E}_{inc} and \mathbf{B}_{inc} are given by (16.139). Since the scattered fields are outgoing waves at infinity, their expansions must be of the form,

$$\begin{aligned} \mathbf{E}_{\text{sc}} &= \frac{1}{2} \sum_{l=1}^{\infty} i^l \sqrt{4\pi(2l+1)} \left[\alpha_{\pm}(l) h_l^{(1)}(kr) \mathbf{X}_{l,\pm 1} \pm \frac{\beta_{\pm}(l)}{k} \nabla \times h_l^{(1)}(kr) \mathbf{X}_{l,\pm 1} \right] \\ \mathbf{B}_{\text{sc}} &= \frac{1}{2} \sum_{l=1}^{\infty} i^l \sqrt{4\pi(2l+1)} \left[-\frac{i\alpha_{\pm}(l)}{k} \nabla \times h_l^{(1)}(kr) \mathbf{X}_{l,\pm 1} \mp i\beta_{\pm}(l) h_l^{(1)}(kr) \mathbf{X}_{l,\pm 1} \right] \end{aligned} \quad (16.141)$$

The coefficients $\alpha_{\pm}(l)$ and $\beta_{\pm}(l)$ will be determined by the boundary conditions on the surface of the scatterer. A priori, it is necessary to keep a full sum over m as well as l in (16.141), but for the restricted class of spherically symmetric problems considered here only $m = \pm 1$ occurs.

Formal expressions for the total scattered and absorbed power in terms of the coefficients of $\alpha(l)$ and $\beta(l)$ can be derived from the scattered and total fields on the surface of a sphere of radius a surrounding the scatterer, as expressed by (9.184) and (9.185). These can be written

$$P_{\text{sc}} = -\frac{ca^2}{8\pi} \operatorname{Re} \int \mathbf{E}_{\text{sc}} \cdot (\mathbf{n} \times \mathbf{B}_{\text{sc}}^*) d\Omega \quad (16.142)$$

$$P_{\text{abs}} = \frac{ca^2}{8\pi} \operatorname{Re} \int \mathbf{E} \cdot (\mathbf{n} \times \mathbf{B}^*) d\Omega \quad (16.143)$$

Here \mathbf{n} is a radially directed outward normal, \mathbf{E}_{sc} and \mathbf{B}_{sc} are given by (16.141), while \mathbf{E} and \mathbf{B} are the sum of the plane wave fields (16.139) and the scattered fields (16.141). Only the transverse parts of the fields enter these equations. We already know that \mathbf{X}_{lm} is transverse. The other type of term in (16.139) and

(16.141) is

$$\nabla \times f_l(r) \mathbf{X}_{lm} = \frac{in\sqrt{l(l+1)}}{r} f_l(r) Y_{lm} + \frac{1}{r} \frac{\partial}{\partial r} [rf_l(r)] \mathbf{n} \times \mathbf{X}_{lm} \quad (16.144)$$

where f_l is any spherical Bessel function of order l satisfying (16.5). When the multipole expansions of the fields are inserted in (16.142) and (16.143), there results a double sum over l and l' of various scalar products of the form $\mathbf{X}_{lm}^* \cdot \mathbf{X}_{l'm'}$, $\mathbf{X}_{lm}^* \cdot (\mathbf{n} \times \mathbf{X}_{l'm'})$ and $(\mathbf{n} \times \mathbf{X}_{lm}^*) \cdot (\mathbf{n} \times \mathbf{X}_{l'm'})$. On integration over angles, the orthogonality relations (16.132) reduce the double sum to a single sum. Each term in the sum involves products of spherical Bessel functions and derivatives of spherical Bessel functions. Use of the Wronskians (16.15) permits the elimination of all the Bessel functions and yields the following expressions for the total scattering and absorption cross sections (the power scattered or absorbed divided by the incident flux, $c/4\pi$):

$$\sigma_{sc} = \frac{\pi}{2k^2} \sum_l (2l+1) [|\alpha(l)|^2 + |\beta(l)|^2] \quad (16.144)$$

$$\sigma_{abs} = \frac{\pi}{2k^2} \sum_l (2l+1) [2 - |\alpha(l)+1|^2 - |\beta(l)+1|^2] \quad (16.145)$$

The total or extinction cross section is the sum of σ_{sc} and σ_{abs} :

$$\sigma_t = -\frac{\pi}{k^2} \sum_l (2l+1) \operatorname{Re} [\alpha(l) + \beta(l)] \quad (16.146)$$

Not surprisingly, these expressions for the cross sections resemble closely the partial wave expansions of quantum-mechanical scattering.*

The differential scattering cross section is obtained by calculating the power radiated into a given solid angle element $d\Omega$ or, equivalently, by taking the absolute square of the normalized scattering amplitude \mathbf{f} , (9.188). Using the result of Problem 16.11(a), we find the scattering cross section for incident polarization ($\epsilon_1 \pm i\epsilon_2$) to be

$$\frac{d\sigma_{sc}}{d\Omega} = \frac{\pi}{2k^2} \left| \sum_l \sqrt{2l+1} [\alpha_{\pm}(l) \mathbf{X}_{l,\pm 1} \pm i\beta_{\pm}(l) \mathbf{n} \times \mathbf{X}_{l,\pm 1}] \right|^2 \quad (16.147)$$

The scattered radiation is in general elliptically polarized. Only if $\alpha_{\pm}(l) = \beta_{\pm}(l)$ for all l would it be circularly polarized. This means that if the incident radiation is linearly polarized, the scattered radiation will be elliptically polarized; if the

* Our results are not completely general. If the sum over m had been included in (16.141), the scattering cross section would have a sum over l and m with the absolute squares of $\alpha(l, m)$ and $\beta(l, m)$. The total cross section would stay as it is, with $\alpha(l) \rightarrow \alpha(l, m = \pm \frac{1}{2})$ and $\beta(l) \rightarrow \beta(l, m = \pm \frac{1}{2})$, depending on the state of polarization of the incident wave (16.130). The absorption cross section can be deduced from taking the difference of σ_t and σ_{sc} .

incident radiation is unpolarized, the scattered radiation will exhibit partial polarization depending upon the angle of observation. Examples of this in the long-wavelength limit were described in Chapter 9 (see Figs. 9.6 and 9.7).

The coefficients $\alpha_{\pm}(l)$ and $\beta_{\pm}(l)$ in (16.141) are determined by the boundary conditions on the fields at $r=a$. Normally this would involve the solution of the Maxwell equations inside the sphere and appropriate matching of solutions across $r=a$. If, however, the scatterer is a sphere of radius a whose electromagnetic properties can be described by a *surface impedance* Z_s (for this the radial variation of the fields just inside the sphere must be rapid compared to the radius), then the boundary conditions take the relatively simple form,

$$\mathbf{E}_{\text{tan}} = \frac{c}{4\pi} Z_s \mathbf{n} \times \mathbf{B} \quad (16.148)$$

where \mathbf{E} and \mathbf{B} are evaluated just outside the sphere. From (16.139), (16.141), and (16.144) we have

$$\begin{aligned} \mathbf{E}_{\text{tan}} = \sum_l i^l \sqrt{4\pi(2l+1)} \left\{ \left[j_l + \frac{\alpha_{\pm}(l)}{2} h_l^{(1)} \right] \mathbf{X}_{l,\pm 1} \right. \\ \left. \pm \frac{1}{x} \frac{\partial}{\partial x} \left[x \left(j_l + \frac{\beta_{\pm}(l)}{2} h_l^{(1)} \right) \right] \mathbf{n} \times \mathbf{X}_{l,\pm 1} \right\} \end{aligned}$$

and

$$\begin{aligned} \mathbf{n} \times \mathbf{B} = \sum_l i^l \sqrt{4\pi(2l+1)} \left\{ \frac{i}{x} \frac{\partial}{\partial x} \left[x \left(j_l + \frac{\alpha_{\pm}(l)}{2} h_l^{(1)} \right) \right] \mathbf{X}_{l,\pm 1} \right. \\ \left. \mp i \left[j_l + \frac{\beta_{\pm}(l)}{2} h_l^{(1)} \right] \mathbf{n} \times \mathbf{X}_{l,\pm 1} \right\} \end{aligned}$$

where $x=ka$ and all the spherical Bessel functions have argument x . The boundary condition (16.148) requires that, for each l value and for each term \mathbf{X}_{lm} and $\mathbf{n} \times \mathbf{X}_{lm}$ separately, the coefficients of \mathbf{E}_{tan} and $\mathbf{n} \times \mathbf{B}$ be proportional, according to

$$\begin{aligned} j_l + \frac{\alpha_{\pm}(l)}{2} h_l^{(1)} &= i \left(\frac{cZ_s}{4\pi} \right) \frac{1}{x} \frac{d}{dx} \left[x \left(j_l + \frac{\alpha_{\pm}(l)}{2} h_l^{(1)} \right) \right] \\ j_l + \frac{\beta_{\pm}(l)}{2} h_l^{(1)} &= i \left(\frac{4\pi}{cZ_s} \right) \frac{1}{x} \frac{d}{dx} \left[x \left(j_l + \frac{\beta_{\pm}(l)}{2} h_l^{(1)} \right) \right] \end{aligned} \quad (16.149)$$

By means of the relation $2j_l = h_l^{(1)} + h_l^{(2)}$, the coefficients $\alpha_{\pm}(l)$ and $\beta_{\pm}(l)$ can be written

$$\alpha_{\pm}(l) + 1 = - \frac{\left[h_l^{(2)} - i \left(\frac{cZ_s}{4\pi} \right) \frac{1}{x} \frac{d}{dx} (x h_l^{(2)}) \right]}{\left[h_l^{(1)} - i \left(\frac{cZ_s}{4\pi} \right) \frac{1}{x} \frac{d}{dx} (x h_l^{(1)}) \right]} \quad (16.150)$$

with $\beta_{\pm}(l)$ having the same form, but with $cZ_s/4\pi$ replaced by its reciprocal. We

note that with the surface impedance boundary condition the coefficients are the same for both states of circular polarization.

For a given Z_s , all the multipole coefficients are determined and the scattering is known in principle. All that remains is to put in numbers. Before proceeding to a specific limit, we make some observations. First, if Z_s is purely imaginary (no dissipation) or if $Z_s = 0$ or $Z_s \rightarrow \infty$, $[\alpha_{\pm}(l) + 1]$ and $[\beta_{\pm}(l) + 1]$ are numbers of modulus unity. This means that $\alpha_{\pm}(l)$ and $\beta_{\pm}(l)$ can be written as

$$\alpha_{\pm}(l) = (e^{2i\delta_l} - 1), \quad \beta_{\pm}(l) = (e^{2i\delta'_l} - 1) \quad (16.151)$$

where the phase angles δ_l and δ'_l are called *scattering phase shifts*. Specifically

$$\left. \begin{aligned} \tan \delta_l &= j_l(ka)/n_l(ka) \\ \tan \delta'_l &= \left[\frac{\frac{d}{dx}(xj_l(x))}{\frac{d}{dx}(xn_l(x))} \right]_{x=ka} \end{aligned} \right\} \quad (16.152)$$

if $Z_s = 0$ (perfectly conducting sphere) and $\delta_l \leftrightarrow \delta'_l$ for $Z_s \rightarrow \infty$.

The second observation is that (16.150) can be simplified in the low and high frequency limits. For $ka \ll l$, the spherical Bessel functions can be approximated according to (16.12). Then we obtain the long-wavelength approximation,

$$\alpha_{\pm}(l) \approx \frac{-2i(ka)^{2l+1}}{(2l+1)[(2l-1)!!]^2} \left[\frac{x - i(l+1)\frac{cZ_s}{4\pi}}{x + il\frac{cZ_s}{4\pi}} \right] \quad (16.153)$$

and the same form for $\beta_{\pm}(l)$, with $(cZ_s/4\pi)$ replaced by its inverse. For $ka \gg l$, we use (16.13) and obtain

$$\alpha_{\pm}(l) \approx \left(\frac{\frac{cZ_s}{4\pi} - 1}{\frac{cZ_s}{4\pi} + 1} \right) e^{2i[(l+1)(\pi/2) - ka]} - 1 \quad (16.154)$$

with $\beta_{\pm}(l) = -\alpha_{\pm}(l)$ via the usual substitution. In the long wavelength limit, independent of the actual value of Z_s , the scattering coefficients $\alpha_{\pm}(l)$, $\beta_{\pm}(l)$ become small very rapidly as l increases. Usually, only the lowest term ($l=1$) need be retained for each multipole series. In the opposite limit of $ka \gg 1$, (16.154) shows that for $l \ll ka$, the successive coefficients have comparable magnitudes, but phases that fluctuate widely. For $l \sim l_{\max} = ka$, there is a transition region and for $l \gg l_{\max}$, (16.153) holds. The use of a partial wave or multipole expansion for such a large number of terms is a delicate matter, necessitating the use of digital computers or approximation schemes of the type discussed in Section 9.13.

We specialize now to the long-wavelength limit ($ka \ll 1$) for a perfectly conducting sphere ($Z_s = 0$), and leave examples of slightly more complexity to the problems. Only the $l = 1$ terms in (16.147) are important. From (16.153) we find

$$\alpha_{\pm}(1) = \frac{-1}{2} \beta_{\pm}(1) \simeq -\frac{2i}{3} (ka)^3$$

In this limit the scattering cross section is

$$\frac{d\sigma_{sc}}{d\Omega} \simeq \frac{2\pi}{3} a^2 (ka)^4 |\mathbf{X}_{1,\pm 1} \mp 2i \mathbf{n} \times \mathbf{X}_{1,\pm 1}|^2 \quad (16.155)$$

From the table on p. 753 we obtain the absolute squared terms,

$$|\mathbf{n} \times \mathbf{X}_{1,\pm 1}|^2 = |\mathbf{X}_{1,\pm 1}|^2 = \frac{3}{16\pi} (1 + \cos^2 \theta) \quad (16.156)$$

The cross terms can be easily worked out:

$$[\pm i(\mathbf{n} \times \mathbf{X}_{1,\pm 1})^* \cdot \mathbf{X}_{1,\pm 1}] = \frac{-3}{8\pi} \cos \theta \quad (16.157)$$

Thus the long-wavelength limit of the differential scattering cross section is

$$\frac{d\sigma}{d\Omega} \simeq a^2 (ka)^4 \left[\frac{5}{8} (1 + \cos^2 \theta) - \cos \theta \right] \quad (16.158)$$

independent of the state of polarization of the incident radiation. The angular

Fig. 16.6 Angular distribution of radiation scattered by a perfectly conducting sphere in the long-wavelength limit ($ka \ll 1$).

distribution of scattered radiation is shown in Fig. 16.6, a polar diagram equivalent to Fig. 9.7. The scattering is predominantly backwards, the marked asymmetry about 90° being caused by the electric dipole-magnetic dipole interference term.

The total cross section in the long-wavelength limit is

$$\sigma = \frac{10\pi}{3} a^2 (ka)^4 \quad (16.159)$$

This is a well-known result, first obtained by Mie and Debye (1908–1909), and already discussed from a different point of view in Section 9.6(c).

The general problem of the scattering of electromagnetic waves by spheres of arbitrary electric and magnetic properties when ka is not small is complicated. It was first systematically attacked by Mie and Debye in 1908–1909. By now, hundreds of papers have been published on the subject. Details of the many aspects of this important problem can be found in the books by *Kerker, King and Wu, Bowman, Senior, and Uslenghi* and other sources cited at the end of the chapter. The book by *Bowman, Senior, and Uslenghi* discusses scattering by other regular shapes besides the sphere.

For scatterers other than spheres, cylinders, etc. there is very little in the way of formal theory. Recently there has been some interesting progress in the development of an approximation scheme by Purcell and Pennypacker in which a scatterer of arbitrary shape and electromagnetic properties is replaced by a coarse-grained lattice array of elementary dipole scatterers whose properties reproduce those of the scatterer. A self-consistent solution to the fields inside and outside the “scatterer” is the sought by numerical means with a high-speed digital computer. This work is cited in the suggested reading at the end of Chapter 9.

16.10 Boundary-Value Problems with Multipole Fields

The scattering of radiation by a conducting sphere is an example of a boundary-value problem with multipole fields. Other examples are the free oscillations of a conducting sphere, the spherical resonant cavity, and scattering by a dielectric sphere. The possibility of resistive losses in conductors adds problems such as Q values of cavities and absorption cross sections, already touched upon, to the list. The general techniques for handling these problems are the same ones as have been met in Section 16.9 and in Chapter 8. The necessary mathematical apparatus has been developed in the present chapter. We will leave the discussion of these examples to the problems at the end of the chapter.

REFERENCES AND SUGGESTED READING

The theory of vector spherical harmonics and multipole vector fields is discussed thoroughly by

Blatt and Weisskopf, Appendix B,

Morse and Feshbach, Section 13.3.

Applications to nuclear multipole radiation are given in

Blatt and Weisskopf, Chapter XII,

Siegbahn, Chapter XIII by S. A. Moszkowski and Chapter XVI (II) by M. Goldhaber and A. W. Sunyar.

A number of books on antennas as well as scattering were cited at the end of Chapter 9.

None of them discusses multipole expansions in a rigorous way, however.

The scattering of radiation by a perfectly conducting sphere is treated briefly by

Morse and Feshbach, pp. 1882–1886,

Panofsky and Phillips, Section 12.9.

Much more elaborate discussions, with arbitrary dielectric and conductive properties for the sphere, are given by

Born and Wolf, Section 13.5,

Stratton, Section 9.25.

Mathematical information on spherical Bessel functions, etc., will be found in

Morse and Feshbach, pp. 1573–6.

Other references on scattering have already been cited at the end of Section 16.9.

PROBLEMS

16.1 Three charges are located along the z axis, a charge $+2q$ at the origin and charges $-q$ at $z = \pm a \cos \omega t$. Determine the lowest nonvanishing multipole moments, the angular distribution of radiation, and the total power radiated. Assume that $ka \ll 1$.

16.2 An almost spherical surface defined by

$$R(\theta) = R_0[1 + \beta P_2(\cos \theta)]$$

has inside of it a uniform volume distribution of charge totaling Q . The small parameter β varies harmonically in time at frequency ω . This corresponds to surface waves on a sphere. Keeping only lowest-order terms in β and making the long-wavelength approximation, calculate the nonvanishing multipole moments, the angular distribution of radiation, and the total power radiated.

16.3 The uniform charge density of Problem 16.2 is replaced by a uniform density of intrinsic magnetization parallel to the z axis and having total magnetic moment M . With the same approximations as above calculate the nonvanishing radiation multipole moments, the angular distribution of radiation, and the total power radiated.

16.4 An antenna consists of a circular loop of wire of radius a located in the x - y plane with its center at the origin. The current in the wire is

$$I = I_0 \cos \omega t = \operatorname{Re} I_0 e^{-i\omega t}$$

(a) Find the expressions for \mathbf{E} , \mathbf{B} in the radiation zone without approximations as to the magnitude of ka . Determine the power radiated per unit solid angle.

(b) What is the lowest nonvanishing multipole moment (Q_{lm} or M_{lm})? Evaluate this moment in the limit $ka \ll 1$.

16.5 Two fixed electric dipoles of dipole moment p are located in a plane a distance $2a$ apart, their axes parallel and perpendicular to the plane, but their moments directed oppositely. The dipoles rotate with constant angular velocity ω about a parallel axis located halfway between them ($\omega \ll c/a$).

(a) Calculate the components of the quadrupole moment.

(b) Show that the angular distribution of radiation is proportional to $(1 - 3 \cos^2 \theta + 4 \cos^4 \theta)$, and that the total power radiated is

$$P = \frac{2cp^2a^2}{5} \left(\frac{\omega}{c} \right)^6$$

16.6 In the long-wavelength limit evaluate all the nonvanishing electric multipole moments for the charge distribution:

$$\rho = Cr^3 e^{-5r/6} Y_{1,1}(\theta, \phi) Y_{2,0}(\theta, \phi) e^{-i\omega_0 t}$$

and determine the angular distribution and total power radiated for each multipole. This charge distribution is appropriate to a transition between the states $n=3$, $l=2$ ($3d$) and $n=2$, $l=1$ ($2p$) in a hydrogen atom.

16.7 The fields representing a transverse magnetic wave propagating in a cylindrical wave guide of radius R are:

$$E_z = J_m(\gamma r) e^{im\phi} e^{i\beta z - i\omega t}, \quad H_z = 0$$

$$E_\phi = \frac{-m\beta E_z}{\gamma^2 r}, \quad H_r = -\frac{k}{\beta} E_\phi$$

$$E_r = \frac{i\beta}{\gamma^2} \frac{\partial E_z}{\partial r}, \quad H_\phi = \frac{k}{\beta} E_r$$

where m is the index specifying the angular dependence, β is the propagation constant, $\gamma^2 = k^2 - \beta^2$ ($k = \omega/c$), where γ is such that $J_m(\gamma R) = 0$. Calculate the ratio of the z component of the electromagnetic angular momentum to the energy in the field. It may be advantageous to perform some integrations by parts, and to use the differential equation satisfied by E_z , in order to simplify your calculations.

16.8 A spherical hole of radius a in a conducting medium can serve as an electromagnetic resonant cavity.

(a) Assuming infinite conductivity, determine the transcendental equations for the characteristic frequencies ω_{lm} of the cavity for TE and TM modes.

(b) Calculate numerical values for the wavelength λ_{lm} in units of the radius a for the four lowest modes for TE and TM waves.

(c) Calculate explicitly the electric and magnetic fields inside the cavity for the lowest TE and lowest TM mode.

16.9 The spherical resonant cavity of Problem 16.8 has nonpermeable walls of large, but finite, conductivity. In the approximation that the skin depth δ is small compared to the cavity radius a , show that the Q of the cavity, defined by equation (8.86), is given by

$$Q = \frac{a}{\delta}, \quad \text{for all TE modes}$$

and

$$Q = \frac{a}{\delta} \left(1 - \frac{l(l+1)}{x_{lm}^2} \right), \quad \text{for TM modes}$$

where $x_{lm} = (a/c)\omega_{lm}$ for TM modes.

16.10 Discuss the normal modes of oscillation of a perfectly conducting solid sphere of radius a in free space. (This problem was solved by J. J. Thomson in the 1880's.)

(a) Determine the characteristic equations for the eigenfrequencies for TE and TM modes of oscillation. Show that the roots for ω always have a negative imaginary part, assuming a time dependence of $e^{-i\omega t}$.

(b) Calculate the eigenfrequencies for the $l=1$ and $l=2$ TE and TM modes. Tabulate the wavelength (defined in terms of the real part of the frequency) in units of the radius a and the decay time (defined as the time taken for the energy to fall to e^{-1} of its initial value) in units of the transit time (a/c) for each of the modes.

16.11 (a) Show that for the scattered wave (16.141) the *normalized* scattering amplitude (9.188) is

$$\mathbf{f} = \frac{1}{ik} \sqrt{\frac{\pi}{2}} \sum_l \sqrt{2l+1} [\alpha_{\pm}(l) \mathbf{X}_{l,\pm 1} \pm i\beta_{\pm}(l) \mathbf{n} \times \mathbf{X}_{l,\pm 1}]$$

where the polarization vector of the incident wave is $(\mathbf{e}_1 \pm i\mathbf{e}_2)/\sqrt{2}$.

(b) Deduce an expression for the total cross section of σ_t from the optical theorem (9.189) and the above expression for \mathbf{f} .

16.12 A circularly polarized plane wave of radiation of frequency $\omega = ck$ is incident on a nonpermeable, conducting sphere of radius a .

(a) Assuming that the conductivity of the sphere is infinite, write down explicit expressions for the electric and magnetic fields near and at the surface of the sphere in the long-wavelength limit, $ka \ll 1$.

(b) Using the techniques of Chapter 8, calculate the power absorbed by the sphere from the incident wave, assuming that the conductivity is large but finite. Express your result as an absorption cross section in terms of the wave number k , the radius a , and the skin depth δ . Assume $ka \ll 1$.

16.13 Discuss the scattering of a plane wave of electromagnetic radiation by a nonpermeable, dielectric sphere of radius a and dielectric constant ϵ .

(a) By finding the fields inside the sphere and matching to the incident plus scattered wave outside the sphere, determine the multipole coefficients in the scattered wave. Define suitable phase shifts for the problem.

(b) Consider the long-wavelength limit ($ka \ll 1$) and determine explicitly the differential and total scattering cross sections. Compare your results with those of Section 9.6(b).

(c) In the limit $\epsilon \rightarrow \infty$ compare your results to those for the perfectly conducting sphere.

16.14 Consider the scattering of a plane wave by a nonpermeable sphere of radius a and very good, but not perfect, conductivity. Assume that $ka \ll 1$ and that the skin depth $\delta < a$.

(a) Show from the analysis of Section 8.1 that

$$\frac{cZ_s}{4\pi} = \frac{k\delta}{2}(1-i)$$

(b) In the long-wavelength limit, show that for $l=1$ the coefficients $\alpha_{\pm}(l)$ and $\beta_{\pm}(l)$ in (16.149) are

$$\alpha_{\pm}(1) \approx -\frac{2i}{3}(ka)^3 \left[\frac{\left(1 - \frac{\delta}{a}\right) - i \frac{\delta}{a}}{\left(1 + \frac{\delta}{2a}\right) + i \frac{\delta}{2a}} \right]$$

$$\beta_{\pm}(1) \approx \frac{4i}{3}(ka)^3$$

(c) Write out explicitly the differential scattering cross section, correct to *first* order in δ/a and lowest order in ka .

(d) Using (16.145), evaluate the absorption cross section. Show that to first order in δ it is $\sigma_{\text{abs}} \approx 3\pi(k\delta)a^2$. How different is the value if $\delta = a$?

17

Radiation Damping, Self-Fields of a Particle, Scattering and Absorption of Radiation by a Bound System

17.1 Introductory Considerations

In the preceding chapters the problems of electrodynamics have been divided into two classes, one in which the sources of charge and current are specified and the resulting electromagnetic fields are calculated, and the other in which the external electromagnetic fields are specified and the motions of charged particles or currents are calculated. Wave guides, cavities, and radiation from prescribed multipole sources are examples of the first type of problem, while motion of charges in electric and magnetic fields and energy-loss phenomena are examples of the second type. Occasionally, as in the discussion of bremsstrahlung, the two problems are combined. But the treatment is a stepwise one—first the motion of the charged particle in an external field is determined, neglecting the emission of radiation; then the radiation is calculated from the trajectory as a given source distribution.

It is evident that this manner of handling problems in electrodynamics can be of only approximate validity. The motion of charged particles in external force fields necessarily involves the emission of radiation whenever the charges are accelerated. The emitted radiation carries off energy, momentum, and angular momentum and so must influence the subsequent motion of the charged particles. Consequently the motion of the sources of radiation is determined, in part, by the manner of emission of the radiation. A correct treatment must include the reaction of the radiation on the motion of the sources.

Why is it that we have taken so long in our discussion of electrodynamics to face this fact? Why is it that many answers calculated in an apparently erroneous way agree so well with experiment? A partial answer to the first question lies in the second. There *are* very many problems in electrodynamics which can be put

with negligible error into one of the two categories described in the first paragraph. Hence it is worth while discussing them without the added and unnecessary complication of including reaction effects. The remaining answer to the first question is that a completely satisfactory treatment of the reactive effects of radiation does not exist. The difficulties presented by this problem touch one of the most fundamental aspects of physics, the nature of an elementary particle. Although partial solutions, workable within limited areas, can be given, the basic problem remains unsolved. One might hope that the transition from classical to quantum-mechanical treatments would remove the difficulties. While there is still hope that this may eventually occur, the present quantum-mechanical discussions are beset with even more elaborate troubles than the classical ones. It is one of the triumphs of comparatively recent years (~ 1948 – 1950) that the concepts of Lorentz covariance and gauge invariance were exploited sufficiently cleverly to circumvent these difficulties in quantum electrodynamics and so allow the calculation of very small radiative effects to extremely high precision, in full agreement with experiment. From a fundamental point of view, however, the difficulties still remain. In this chapter we will consider only the classical aspects, but will indicate some of the quantum-mechanical analogs along the way.

The question as to why many problems can apparently be handled neglecting reactive effects of the radiation has the obvious answer that such effects must be of negligible importance. To see qualitatively when this is so, and to obtain semiquantitative estimates of the ranges of parameters where radiative effects are or are not important, we need a simple criterion. One such criterion can be obtained from energy considerations. If an external force field causes a particle of charge e to have an acceleration of typical magnitude a for a period of time T , the energy radiated is of the order of

$$E_{\text{rad}} \sim \frac{2e^2 a^2 T}{3c^2} \quad (17.1)$$

from the Larmor formula (14.22). If this energy lost in radiation is negligible compared to the relevant energy E_0 of the problem, we can expect that radiative effects will be unimportant. But if $E_{\text{rad}} \geq E_0$, the effects of radiation reaction will be appreciable. The criterion for the regime where radiative effects are unimportant can thus be expressed by

$$E_{\text{rad}} \ll E_0 \quad (17.2)$$

The specification of the relevant energy E_0 demands a little care. We will distinguish two apparently different situations, one in which the particle is initially at rest and is acted on by the applied force only for the finite interval T , and one where the particle undergoes continual acceleration, e.g., in quasiperiodic motion at some characteristic frequency ω_0 . For the particle at rest initially a typical energy is evidently its kinetic energy after the period of

acceleration. Thus

$$E_0 \sim m(aT)^2$$

The criterion (17.2) for the unimportance of radiative effects then becomes

$$\frac{2}{3} \frac{e^2 a^2 T}{c^3} \ll m a^2 T^2$$

or

$$T \gg \frac{2}{3} \frac{e^2}{mc^3}$$

It is useful to define the *characteristic time* in this relation as

$$\tau = \frac{2}{3} \frac{e^2}{mc^3} \quad (17.3)$$

Then the conclusion is that for time T long compared to τ radiative effects are unimportant. Only when the force is applied so suddenly and for such a short time that $T \sim \tau$ will radiative effects modify the motion appreciably. It is useful to note that the longest characteristic time τ for charged particles is for electrons and that its value is $\tau = 6.26 \times 10^{-24}$ sec. This is of the order of the time taken for light to travel 10^{-13} cm. Only for phenomena involving such distances or times will we expect radiative effects to play a *crucial* role.

If the motion of the charged particle is quasi-periodic with a typical amplitude d and characteristic frequency ω_0 , the mechanical energy of motion can be identified with E_0 and is of the order of

$$E_0 \sim m\omega_0^2 d^2$$

The accelerations are typically $a \sim \omega_0^2 d$, and the time interval $T \sim (1/\omega_0)$. Consequently criterion (17.2) is

$$\frac{2e^2\omega_0^4 d^2}{3c^3\omega_0} \ll m\omega_0^2 d^2$$

or

$$\omega_0 \tau \ll 1 \quad (17.4)$$

where τ is given by (17.3). Since ω_0^{-1} is a time appropriate to the mechanical motion, again we see that, if the relevant mechanical time interval is long compared to the characteristic time τ (17.3), radiative reaction effects on the motion will be unimportant.

The examples of the last two paragraphs show that the reactive effects of radiation on the motion of a charged particle can be expected to be important if the external forces are such that the motion changes appreciably in times of the order of τ or over distances of the order of $c\tau$. This is a general criterion within the framework of classical electrodynamics. For motions less violent, the reactive effects are sufficiently small that they have a negligible effect on the short-term motion. Their long-term, cumulative effects can be taken into account in an approximate way, as we will see immediately.

17.2 Radiative Reaction Force from Conservation of Energy

The question now arises as to how to include the reactive effects of radiation in the equations of motion for a charged particle. We begin with a simple plausibility argument based on conservation of energy for a nonrelativistic charged particle. A more fundamental derivation and the incorporation of relativistic effects will be deferred to later sections.

If the emission of radiation is neglected, a charged particle of mass m and charge e acted on by an external force \mathbf{F}_{ext} moves according to the Newton equation of motion:

$$m\dot{\mathbf{v}} = \mathbf{F}_{\text{ext}} \quad (17.5)$$

Since the particle is accelerated, it emits radiation at a rate given by the Larmor power formula (14.22),

$$P(t) = \frac{2}{3} \frac{e^2}{c^3} (\dot{\mathbf{v}})^2 \quad (17.6)$$

To account for this radiative energy loss and its effect on the motion of the particle we modify the Newton equation (17.5) by adding a *radiative reaction force* \mathbf{F}_{rad} :

$$m\dot{\mathbf{v}} = \mathbf{F}_{\text{ext}} + \mathbf{F}_{\text{rad}} \quad (17.7)$$

While \mathbf{F}_{rad} is not determined at this stage, we can see some of the requirements it “must” satisfy:

- \mathbf{F}_{rad} “must” (1) vanish if $\dot{\mathbf{v}} = 0$, since then there is no radiation;
- (2) be proportional to e^2 , since (a) the radiated power is proportional to e^2 , and (b) the sign of the charge cannot enter in radiative effects;
- (3) in fact involve the characteristic time τ (17.3), since that is apparently the only parameter of significance available.

We will determine the form of \mathbf{F}_{rad} by demanding that the work done by this force on the particle in the time interval $t_1 < t < t_2$ be equal to the negative of the energy radiated in that time. Then energy will be conserved, at least over the interval (t_1, t_2) . With the Larmor result (17.6), this requirement is

$$\int_{t_1}^{t_2} \mathbf{F}_{\text{rad}} \cdot \mathbf{v} \, dt = - \int_{t_1}^{t_2} \frac{2}{3} \frac{e^2}{c^3} \dot{\mathbf{v}} \cdot \dot{\mathbf{v}} \, dt$$

The second integral can be integrated by parts to yield

$$\int_{t_1}^{t_2} \mathbf{F}_{\text{rad}} \cdot \mathbf{v} \, dt = \frac{2}{3} \frac{e^2}{c^3} \int_{t_1}^{t_2} \ddot{\mathbf{v}} \cdot \mathbf{v} \, dt - \frac{2}{3} \frac{e^2}{c^3} (\dot{\mathbf{v}} \cdot \mathbf{v}) \Big|_{t_1}^{t_2}$$

If the motion is periodic or such that $(\dot{\mathbf{v}} \cdot \mathbf{v}) = 0$ at $t = t_1$ and $t = t_2$, we may write

$$\int_{t_1}^{t_2} \left(\mathbf{F}_{\text{rad}} - \frac{2}{3} \frac{e^2}{c^3} \ddot{\mathbf{v}} \right) \cdot \mathbf{v} \, dt = 0$$

Then it is permissible to identify the radiative reaction force as

$$\mathbf{F}_{\text{rad}} = \frac{2}{3} \frac{e^2}{c^3} \ddot{\mathbf{v}} = m\tau \ddot{\mathbf{v}} \quad (17.8)$$

The modified equation of motion then reads

$$m(\dot{\mathbf{v}} - \tau \ddot{\mathbf{v}}) = \mathbf{F}_{\text{ext}} \quad (17.9)$$

Equation (17.9) is sometimes called the *Abraham-Lorentz equation of motion*. It can be considered as an equation which includes in some approximate and time-average way the reactive effects of the emission of radiation. The equation can be criticized on the grounds that it is second order in time, rather than first, and therefore runs counter to the well-known requirements for a dynamical equation of motion. This difficulty manifests itself immediately in the so-called “runaway” solutions. If the external force is zero, it is obvious that (17.9) has two possible solutions,

$$\dot{\mathbf{v}}(t) = \begin{cases} 0 \\ \mathbf{a}e^{t/\tau} \end{cases} \quad (17.10)$$

where \mathbf{a} is the acceleration at $t=0$. Only the first solution is reasonable. The method of derivation shows that the second solution is unacceptable, since $(\dot{\mathbf{v}} \cdot \mathbf{v}) \neq 0$ at t_1 and t_2 . It is clear that the equation is useful only in the domain where the reactive term is a small correction. Then the radiative reaction can be treated as a perturbation producing slow or small changes in the state of motion of the particle. The problem of the “runaway” solutions can be avoided by replacing (17.9) by an integrodifferential equation (see Section 17.6).

To illustrate the use of (17.9) to account for small radiative effects we consider a particle moving in an attractive, conservative, central force field. In the absence of radiation reaction, the particle's energy and angular momentum are conserved and determine the motion. The emission of radiation causes changes in these quantities. Provided the accelerations are not too violent, the energy and angular momentum will change appreciably only in a time interval long compared to the characteristic period of the motion. Thus the motion will instantaneously be essentially the same as in the absence of radiative reaction. The long-term changes can be described by averages over the particle's unperturbed orbit.

If the conservative central force field is described by a potential $V(r)$, the acceleration, neglecting reactive effects, is

$$\dot{\mathbf{v}} = -\frac{1}{m} \left(\frac{dV}{dr} \right) \frac{\mathbf{r}}{r} \quad (17.11)$$

By conservation of energy the rate of change of the particle's total energy is

given by the negative of the Larmor power:

$$\frac{dE}{dt} = -\frac{2}{3} \frac{e^2}{c^3} (\dot{\mathbf{v}})^2 = -\frac{2e^2}{3m^2c^3} \left(\frac{dV}{dr} \right)^2$$

While the definition of τ (17.3) this can be written

$$\frac{dE}{dt} = -\frac{\tau}{m} \left(\frac{dV}{dr} \right)^2 \quad (17.12)$$

Since the change in energy is assumed to be small in one cycle of the orbit, the right-hand side may be replaced by its time-averaged value in terms of the Newtonian orbit. Then we obtain

$$\frac{dE}{dt} \approx -\frac{\tau}{m} \left\langle \left(\frac{dV}{dr} \right)^2 \right\rangle \quad (17.13)$$

The secular change in angular momentum can be found by considering the vector product of (17.9) with the radius vector \mathbf{r} . Since the angular momentum is $\mathbf{L} = m\mathbf{r} \times \mathbf{v}$, we find

$$\frac{d\mathbf{L}}{dt} = \mathbf{r} \times \mathbf{F}_{\text{ext}} + m\tau \mathbf{r} \times \ddot{\mathbf{v}} \quad (17.14)$$

Since the external force is central, the applied torque vanishes. But the radiative torque term can be expressed as

$$m\tau \mathbf{r} \times \ddot{\mathbf{v}} = \tau \left(\frac{d^2\mathbf{L}}{dt^2} - m\mathbf{v} \times \dot{\mathbf{v}} \right) \quad (17.15)$$

The angular momentum is assumed to change slowly in time, certainly when time is measured in units of τ . Consequently it is consistent to omit in (17.15) the second derivative of \mathbf{L} with respect to t and to substitute $\dot{\mathbf{v}}$ from the unperturbed equation of motion (17.11). Then the rate of change of angular momentum can be written as

$$\frac{d\mathbf{L}}{dt} \approx -\frac{\tau}{m} \left\langle \frac{1}{r} \frac{dV}{dr} \right\rangle \mathbf{L} \quad (17.16)$$

where a time average over the instantaneous orbit has been performed, as in (17.13).

Equations (17.13) and (17.16) determine how the particle orbit changes as a function of time because of radiative reaction. Although the detailed behavior depends on the specific law of force, some qualitative statements can be made. If the characteristic frequency of motion is ω_0 , the average value in (17.16) can be written

$$\frac{\tau}{m} \left\langle \frac{1}{r} \frac{dV}{dr} \right\rangle \sim \frac{\tau}{m} m\omega_0^2 = \omega_0^2 \tau$$

with some dimensionless numerical coefficient of the order of unity. This shows that the characteristic time over which the angular momentum changes is of the order of $1/(\omega_0\tau)\omega_0$. This time is very long compared to the orbital period $2\pi/\omega_0$, provided $\omega_0\tau \ll 1$. Similar arguments can be made with the energy equations.

These equations including radiative effects can be used to discuss practical problems such as the moderation time of a mu or pi meson in cascading from an orbit of very large quantum number around a nucleus down to the low-lying orbits. Over most of the time interval the quantum numbers are sufficiently large that the classical description of continuous motion is an adequate approximation. Discussion of examples of this kind will be left to the problems.

17.3 Abraham-Lorentz Evaluation of the Self-Force

The derivation of the radiation reaction force in the previous section, while plausible, is certainly not rigorous or fundamental. The problem is to give a satisfactory account of the reaction back on the charged particle of its own radiation fields. Thus any systematic discussion must consider the charge structure of the particle and its self-fields. Abraham (1903) and Lorentz (1904) made the first attempt at such a treatment by trying to make a purely electromagnetic model of a charged particle. Our discussion is patterned after that given by Lorentz in his book, *Theory of Electrons*, Note 18, p. 252.

Let us consider a single charged particle of total charge e with a sharply localized charge density $\rho(\mathbf{x})$ in the particle's rest frame. The particle is in external electromagnetic fields, $\mathbf{E}_{\text{ext}}(\mathbf{x}, t)$, $\mathbf{B}_{\text{ext}}(\mathbf{x}, t)$. We have seen in Sections 6.8 and 12.10 that the rate of change of mechanical momentum plus electromagnetic momentum in a given volume vanishes, provided there is no flow of momentum out of or into the volume. Abraham and Lorentz proposed that the apparently mechanical momentum of a charged particle is actually electromagnetic in origin. Then the momentum-conservation law can be phrased,

$$\frac{d\mathbf{G}}{dt} = 0$$

or equivalently in terms of the Lorentz force density (12.121),

$$\int \left(\rho \mathbf{E} + \frac{1}{c} \mathbf{J} \times \mathbf{B} \right) d^3x = 0 \quad (17.17)$$

In this equation the fields are the *total* fields, and the integration is over the volume of the particle.

In order that (17.17) take on the form of the Newton equation of motion

$$\frac{d\mathbf{p}}{dt} = \mathbf{F}_{\text{ext}}$$

we decompose the total fields into the external fields and the self-fields \mathbf{E}_s , \mathbf{B}_s due to the particle's own charge and current densities, ρ and \mathbf{J} :

$$\left. \begin{aligned} \mathbf{E} &= \mathbf{E}_{\text{ext}} + \mathbf{E}_s \\ \mathbf{B} &= \mathbf{B}_{\text{ext}} + \mathbf{B}_s \end{aligned} \right\} \quad (17.18)$$

Then (17.17) can be written as the Newton equations of motion, with the external force as

$$\mathbf{F}_{\text{ext}} = \int \left(\rho \mathbf{E}_{\text{ext}} + \frac{1}{c} \mathbf{J} \times \mathbf{B}_{\text{ext}} \right) d^3x \quad (17.19)$$

and the rate of change of momentum of the particle as

$$\frac{d\mathbf{p}}{dt} = - \int \left(\rho \mathbf{E}_s + \frac{1}{c} \mathbf{J} \times \mathbf{B}_s \right) d^3x \quad (17.20)$$

Provided the external fields vary only slightly over the extent of the particle, the external force (17.19) becomes just the ordinary Lorentz force on a particle of charge e and velocity \mathbf{v} .

To calculate the self-force [the integral on the right side of (17.20)] it is necessary to have a model of the charged particle. We will assume for simplicity that:

- (a) the particle is instantaneously at rest;
- (b) the charge distribution is rigid and spherically symmetric.

Our results will then necessarily be restricted to nonrelativistic motions and will lack the proper Lorentz transformation properties. These deficiencies can be remedied later.

For a particle instantaneously at rest (17.20) becomes

$$\frac{d\mathbf{p}}{dt} = - \int \rho(\mathbf{x}, t) \mathbf{E}_s(\mathbf{x}, t) d^3x \quad (17.21)$$

The self-field can be expressed in terms of the self-potentials, \mathbf{A} and Φ , so that

$$\frac{d\mathbf{p}}{dt} = \int \rho(\mathbf{x}, t) \left[\nabla \Phi(\mathbf{x}, t) + \frac{1}{c} \frac{\partial \mathbf{A}}{\partial t}(\mathbf{x}, t) \right] d^3x \quad (17.22)$$

The potentials are given by $A^\alpha = (\Phi, \mathbf{A})$:

$$A^\alpha(\mathbf{x}, t) = \frac{1}{c} \int \frac{[J^\alpha(\mathbf{x}', t')]_{\text{ret}}}{R} d^3x' \quad (17.23)$$

with $J^\alpha = (c\rho, \mathbf{J})$ and $\mathbf{R} = \mathbf{x} - \mathbf{x}'$.

In (17.23) the 4-current must be evaluated at the retarded time t' . This differs from the time t by a time of the order of $\Delta t \sim (a/c)$, where a is the dimension of the particle. For a highly localized charge distribution this time interval is extremely short. During such a short time the motion of the particle can be assumed to change only slightly. Consequently it is natural to make a Taylor

series expansion in (17.23) around the time $t' = t$. Since $[\]_{\text{ret}}$ means evaluated at $t' = t - (R/c)$, any retarded quantity has the expansion,

$$[\]_{\text{ret}} = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \left(\frac{R}{c} \right)^n \frac{\partial^n}{\partial t^n} [\]_{t'=t} \quad (17.24)$$

With this expansion for the retarded 4-current in (17.23), expression (17.22) becomes

$$\frac{d\mathbf{p}}{dt} = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \frac{1}{c^n} \int d^3x \int d^3x' \rho(\mathbf{x}, t) \frac{\partial^n}{\partial t^n} \left[\rho(\mathbf{x}', t) \nabla R^{n-1} + \frac{R^{n-1}}{c^2} \frac{\partial \mathbf{J}(\mathbf{x}', t)}{\partial t} \right]$$

Consider the $n=0$ and $n=1$ terms in the scalar potential part (the first term in the square bracket) of the right-hand side. For $n=0$ the term is proportional to

$$\int d^3x \int d^3x' \rho(\mathbf{x}, t) \rho(\mathbf{x}', t) \nabla \left(\frac{1}{R} \right)$$

This is just the electrostatic self-force. For spherically symmetric charge distributions it vanishes. The $n=1$ term is identically zero, since it involves ∇R^{n-1} . Thus the first nonvanishing contribution from the scalar potential part comes from $n=2$. This means that we can change the summation indices so that the sum now reads

$$\frac{d\mathbf{p}}{dt} = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \frac{1}{c^{n+2}} \int d^3x \int d^3x' \rho(\mathbf{x}, t) R^{n-1} \frac{\partial^{n+1}}{\partial t^{n+1}} \left\{ \begin{array}{l} \\ \end{array} \right\} \quad (17.25)$$

where

$$\left\{ \begin{array}{l} \\ \end{array} \right\} = \mathbf{J}(\mathbf{x}', t) + \frac{\partial \rho}{\partial t}(\mathbf{x}', t) \frac{\nabla R^{n+1}}{(n+1)(n+2)R^{n-1}}$$

With the continuity equation for charge and current densities, the curly bracket in (17.25) can be written

$$\left\{ \begin{array}{l} \\ \end{array} \right\} = \mathbf{J}(\mathbf{x}', t) - \frac{\mathbf{R}}{n+2} \nabla' \cdot \mathbf{J}(\mathbf{x}', t)$$

In the integral over d^3x' we can integrate the second term by parts. We then have

$$\begin{aligned} - \int d^3x' R^{n-1} \frac{\mathbf{R}}{n+2} \nabla' \cdot \mathbf{J} &= + \frac{1}{n+2} \int d^3x' (\mathbf{J} \cdot \nabla') R^{n-1} \mathbf{R} \\ &= \frac{-1}{n+2} \int d^3x' R^{n-1} \left(\mathbf{J} + (n-1) \frac{\mathbf{J} \cdot \mathbf{R}}{R^2} \mathbf{R} \right) \end{aligned}$$

This means that the curly bracket in (17.25) is effectively equal to

$$\left\{ \begin{array}{l} \\ \end{array} \right\} = \left(\frac{n+1}{n+2} \right) \mathbf{J}(\mathbf{x}', t) - \left(\frac{n-1}{n+2} \right) \frac{(\mathbf{J} \cdot \mathbf{R}) \mathbf{R}}{R^2} \quad (17.26)$$

For a rigid charge distribution the current is

$$\mathbf{J}(\mathbf{x}', t) = \rho(\mathbf{x}', t) \mathbf{v}(t)$$

If the charge distribution is spherically symmetric, the only relevant direction in the problem is that of $\mathbf{v}(t)$. Consequently in the integration over d^3x and d^3x' only the component of (17.26) along the direction of $\mathbf{v}(t)$ survives. Hence (17.26) is equivalent to

$$\{ \} = \rho(\mathbf{x}', t) \mathbf{v}(t) \left[\frac{n+1}{n+2} - \frac{n-1}{n+2} \left(\frac{\mathbf{R} \cdot \mathbf{v}}{Rv} \right)^2 \right]$$

Furthermore all directions of \mathbf{R} are equally probable. This means that the second term above can be replaced by its average value of $\frac{1}{3}$. This leads to the final simple form of our curly bracket in (17.25):

$$\{ \} = \frac{2}{3} \rho(\mathbf{x}', t) \mathbf{v}(t) \quad (17.27)$$

With (17.27) in (17.25) the self-force becomes, apart from neglected nonlinear terms in time derivatives of \mathbf{v} (which appear for $n \geq 4$),

$$\frac{d\mathbf{p}}{dt} = \sum_{n=0}^{\infty} \frac{(-1)^n}{c^{n+2}} \frac{2}{3n!} \frac{\partial^{n+1} \mathbf{v}}{\partial t^{n+1}} \int d^3x' \int d^3x \rho(\mathbf{x}') R^{n-1} \rho(\mathbf{x}) \quad (17.28)$$

To understand the meaning of (17.28) we consider the first few terms in the expansion:

$$\left. \begin{aligned} \left(\frac{d\mathbf{p}}{dt} \right)_0 &= \frac{2}{3c^2} \dot{\mathbf{v}} \int d^3x \int d^3x' \frac{\rho(\mathbf{x}) \rho(\mathbf{x}')}{R} \\ \left(\frac{d\mathbf{p}}{dt} \right)_1 &= \frac{-2}{3c^3} \ddot{\mathbf{v}} \int d^3x \int d^3x' \rho(\mathbf{x}) \rho(\mathbf{x}') = -\frac{2e^2}{3c^3} \ddot{\mathbf{v}} \\ \left(\frac{d\mathbf{p}}{dt} \right)_n &\sim \frac{e^2}{n! c^{n+2}} \mathbf{v}^{(n+1)} a^{n-1} \end{aligned} \right\} \quad (17.29)$$

In the third expression a is a length characteristic of the extension of the charge distribution of the particle. We note that for $n \geq 2$ the terms in the expansion vanish in the limit of a point particle ($a \rightarrow 0$). Thus for very localized charge distributions we need only consider the $n=0$ and $n=1$ contributions. The $n=1$ term is just the radiative reaction force already found in (17.9). It is independent of the structure of the particle, depending only on its total charge. Our present derivation can be considered as placing it on a much more fundamental footing than the treatment of Section 17.2.

The $n=0$ term in (17.29) deserves special attention. The double integral is proportional to the electrostatic self-energy U of the charge distribution,

$$U = \frac{1}{2} \int d^3x \int d^3x' \frac{\rho(\mathbf{x}) \rho(\mathbf{x}')}{R} \quad (17.30)$$

Consequently the $n=0$ term can be expressed as

$$\left(\frac{d\mathbf{p}}{dt} \right)_0 = \frac{4}{3} \frac{U}{c^2} \dot{\mathbf{v}} \quad (17.31)$$

This has the general form required of a rate of change of momentum. The electrostatic self-energy divided by c^2 can be identified with the electromagnetic mass of the particle:

$$m_e = \frac{U}{c^2} \quad (17.32)$$

Then the Newton equation of motion for the Abraham-Lorentz model takes the form,

$$\left(\frac{4}{3}m_e\right)\dot{\mathbf{v}} - \frac{2e^2}{3c^3}\ddot{\mathbf{v}} = \mathbf{F}_{\text{ext}} \quad (17.33)$$

provided higher terms in expansion (17.28) are neglected. This is the same as (17.9), apart from the strange factor of $\frac{4}{3}$ multiplying the electromagnetic mass.

17.4 Difficulties with the Abraham-Lorentz Model

Although the Abraham-Lorentz approach is a significant step towards a fundamental description of a charged particle, it is deficient in several respects.

1. One obvious deficiency is the nonrelativistic nature of the model. For the reactive force term alone a relativistic generalization can be made easily (see Problem 17.4), but that in itself is not sufficient.
2. The electromagnetic mass enters with an incorrect coefficient in (17.33). This is a symptom of improper Lorentz covariance properties inherent in the model, as will become clearer in the following section.
3. If we wish to be able to ignore the higher terms in the self-force expansion, we must take $a \rightarrow 0$. But the electromagnetic mass is of the order $(e^2/c^2 a)$. Hence, in the limit $a \rightarrow 0$, the mass becomes infinite. If we wish to keep the mass of the order of the observed mass m of the particle, the extent of the charge distribution must be $a \sim r_0$, where

$$r_0 = \frac{e^2}{mc^2}$$

For electrons this distance, called the *classical electron radius*, is 2.82×10^{-13} cm. Although this is very small, motions can be envisioned as sufficiently violent that for such a finite extent the higher terms in the expansion would become significant.* Thus, if the particle has a finite extent, the truncated theory must be considered as only an approximate description.

* Successive terms in the expansion are in the ratio $\left(\frac{a}{c} \frac{d^{n+2}v}{dt^{n+2}} / \frac{d^{n+1}v}{dt^{n+1}}\right)$. This means that the motion must change appreciably in a time interval (a/c) . With $a \sim e^2/mc^2$, this time interval is just τ , given by (17.3). We thus return to the same criterion as before.

4. The localized charge distribution must have forces of nonelectromagnetic character holding it stable. Thus the idea of a purely electromagnetic model for matter must be abandoned within the framework of the Maxwell equations and special relativity. We know of strong, nonelectromagnetic forces in nature. These interactions give the particles that partake in them, called hadrons, finite extensions in space. The distribution of charge and magnetization can be probed by the scattering of electrons and mu-mesons, under the assumption that these probes are point charges and that the laws of electrodynamics hold at close distances. For neutrons and protons in detail, and in more fragmentary form for other hadrons, it is found that the extensions of charge and magnetization are of the order of $(0.5-1.0) \times 10^{-13}$ cm. This is somewhat smaller than the classical electron radius r_0 , but of the same order of magnitude. There may be some deep significance to this occurrence, but at our present level of understanding a much more relevant fact is that the Compton wavelength of the pi-meson, the lightest quantum of the nuclear force field, is $\hbar/m_\pi c \approx 1.4 \times 10^{-13}$ cm. Presumably it and other similar hadronic lengths govern the extensions seen in electron scattering experiments.

The charged leptons (electrons and mu-mesons) seem to have only electromagnetic and weak interactions. They are thus candidates for a quantum-mechanical generalization of the Abraham-Lorentz model. As mentioned in the Introduction, experiments on electrons at least show no evidence of structure or finite extension at the level of 10^{-15} cm. This fact is totally inexplicable in the classical context of an extended distribution of charge. We know, of course, that quantum effects enter at distances of the order of $\hbar/mc = 137r_0$. A purely classical electromagnetic model therefore has little relevance to the real world.

Nonelectromagnetic forces imply a contribution m_0 to the mass of a particle from such forces. Within the framework of the Abraham-Lorentz model as discussed so far, this additional mass merely appears as an added coefficient of the acceleration in (17.33).

17.5 Covariant Definitions of Electromagnetic Energy and Momentum

A major problem in the Abraham-Lorentz model is the lack of proper covariance of the electromagnetic self-energy and self-momentum, as manifested by the anomalous factor of $\frac{4}{3}$ in the inertia, first found by J. J. Thomson (1881). The root of this difficulty can be traced to the use of the familiar energy and momentum densities,

$$u = \frac{1}{8\pi} (\mathbf{E}^2 + \mathbf{B}^2), \quad \mathbf{g} = \frac{1}{4\pi c} (\mathbf{E} \times \mathbf{B}) \quad (17.34)$$

in an uncritical fashion. It is customary (see Section 6.8) to define the total electromagnetic energy and momentum as the three-dimensional volume integrals of these densities at fixed time. This is allowable in the discussion of the Poynting theorem for an observer at rest in the inertial frame in which the fields are defined, but is not defensible in general if the total electromagnetic 4-momentum in different inertial frames is to be considered. The densities (17.34) are elements of the symmetric electromagnetic stress tensor $\Theta^{\alpha\beta}$, (12.115). As has already been mentioned in Section 12.10(a), the 3-space integral of Θ^{00} and Θ^{0i} at fixed time do not transform as the components of a 4-vector unless the tensor satisfies $\partial_\alpha \Theta^{\alpha\beta} = 0$, that is, for sourcefree fields. For a classical extended charged particle with a nonvanishing charge and current density the electromagnetic stress tensor $\Theta^{\alpha\beta}$ is not divergenceless [see (12.118)]. Consequently the usual 3-space integrals of u and \mathbf{g} cannot represent the electromagnetic energy and momentum of a charged particle consistently in all inertial frames.

In 1906 Poincaré gave a solution to the problem of the covariance of the energy and momentum of the Abraham-Lorentz particle and also its stability by side-stepping the question of the transformation properties of the *electromagnetic* energy and momentum separately. Poincaré remarked that a purely electromagnetic charged particle was impossible (classically) because the electric charge distribution by itself is unstable. Nonelectric forces are necessary to hold the charge in place. Poincaré then postulated a nonelectromagnetic stress tensor $P^{\alpha\beta}$ that should be added to $\Theta^{\alpha\beta}$ to give the total self-stress tensor $S^{\alpha\beta}$:

$$S^{\alpha\beta} = \Theta^{\alpha\beta} + P^{\alpha\beta}$$

The particle's total 4-momentum was then defined to be

$$cP^\alpha = \int S^{\alpha 0} d^3x \quad (17.35)$$

where the integral is over all of 3-space at a fixed time. It can be shown that (17.35) transforms as a 4-vector provided that in the rest frame of the particle ($\mathbf{P}=0$),

$$\int S^{(0)ij} d^3x^{(0)} = 0 \quad (17.36)$$

where $i, j=1, 2, 3$ and the superscript (0) indicates the rest frame. This requirement is that the total self-stress (in the three-dimensional sense) vanish, just the condition for mechanical stability. The vanishing of the total self-stress in the rest frame can be related to the differential requirement,

$$\partial_\alpha S^{\alpha\beta} = 0$$

We are thus led back to the same situation as for sourcefree radiation. If the Lorentz covariant stress tensor has a vanishing 4-divergence, then spatial

integrals at fixed time of the form (17.35) can represent properly the conserved energy-momentum 4-vector.

Poincaré's solution has some virtues, but it has deficiencies, too. It requires unknown *Poincaré stresses* in order to provide stability. It avoids the question of the transformation properties of the electromagnetic part of the energy and momentum of any system.

The correct 4-vector character for electromagnetic energy and momentum, even in the presence of sources, can be assured by some care. The expressions,

$$\left. \begin{aligned} E'_e &= \frac{1}{8\pi} \int (\mathbf{E}'^2 + \mathbf{B}'^2) d^3x' \\ \mathbf{P}'_e &= \frac{1}{4\pi c} \int \mathbf{E}' \times \mathbf{B}' d^3x' \end{aligned} \right\} \quad (17.37)$$

can be considered to define the energy and momentum in some particular inertial frame K' . The integrands in (17.37) are elements of the second-rank tensor $\Theta^{\alpha\beta}$. Evidently we must contract one of the tensor indices with a 4-vector, and the 4-vector must be such as to reduce to d^3x' in the inertial frame K' . We define the timelike 4-vector,

$$d\sigma^\beta = n^\beta d^3\sigma \quad (17.38)$$

where $d^3\sigma$ is an invariant element of three-dimensional "area" on a spacelike hyperplane in four dimensions. The normal to the hyperplane n^β has components (1, 0, 0, 0) in K' . The invariant $d^3\sigma$ is evidently $d^3\sigma = n_\beta d\sigma^\beta = d^3x'$. If the inertial frame K' moves with velocity $c\boldsymbol{\beta}$ with respect to an inertial frame K , then in K the 4-vector n^β is

$$n^\beta = (\gamma, \gamma\boldsymbol{\beta}) \quad (17.39)$$

The general definition of the electromagnetic 4-momentum in any frame is therefore

$$cP_e^\alpha = \int \Theta^{\alpha\beta} d\sigma_\beta = \int \Theta^{\alpha\beta} n_\beta d^3\sigma \quad (17.40)$$

In K' , n_β has only a time component. With $d^3\sigma = d^3x'$, this covariant expression reduces to (17.37). But in the frame K , $n_\beta = (\gamma, -\gamma\boldsymbol{\beta})$ and the covariant definition has time and space components,

$$\left. \begin{aligned} cP_e^0 &= \gamma \int (u - \mathbf{v} \cdot \mathbf{g}) d^3\sigma \\ cP_e^i &= \gamma \int (cg^i + T_{ij}^{(M)}\beta^j) d^3\sigma \end{aligned} \right\} \quad (17.41)$$

where $T_{ij}^{(M)}$ is the 3×3 Maxwell stress tensor (6.120). If desired, the invariant volume element $d^3\sigma = d^3x'$ can be suppressed in favor of the volume element d^3x in the frame K by means of $d^3x' = \gamma d^3x$ (integration at fixed time t).

The definitions (17.40) or (17.41) of the electromagnetic 4-momentum afford a covariant definition starting from the naive expressions (17.37) in any frame K' . Different choices of the frame K' lead to different 4-vectors, of course, but that is no cause for alarm.* There is a natural choice of the frame K' if the electromagnetic mass of the fields is nonvanishing, namely, the rest frame in which

$$\frac{1}{4\pi c} \int \mathbf{E}^{(0)} \times \mathbf{B}^{(0)} d^3x^{(0)} = 0 \quad (17.42)$$

We denote this frame where the total electromagnetic momentum \mathbf{P}_e is zero as $K^{(0)}$ and attach superscripts zero on quantities in that frame to make it clear that it is a special choice of the frame K' . According to (17.37) the electromagnetic rest energy is then

$$E_e^{(0)} = m_e c^2 = \frac{1}{8\pi} \int [\mathbf{E}^{(0)2} + \mathbf{B}^{(0)2}] d^3x^{(0)} \quad (17.43)$$

In the frame K the electromagnetic energy and momentum are given by (17.41) where now \mathbf{v} is the velocity of the rest frame $K^{(0)}$ in K .

For electromagnetic configurations in which all the charges are at rest in some frame (the Abraham-Lorentz model of a charged particle is one example), the general formulas can be reduced to more attractive and transparent forms. Clearly the frame where all the charges are at rest is $K^{(0)}$ since there all is electrostatic and the magnetic field vanishes everywhere in 3-space. For such electrostatic configurations, the magnetic field is given without approximation in the frame K by

$$\mathbf{B} = \boldsymbol{\beta} \times \mathbf{E} \quad (17.44)$$

This can be verified from (11.149). The integrand in the first equation of (17.41) is thus

$$\begin{aligned} (u - \mathbf{v} \cdot \mathbf{g}) &= \frac{1}{8\pi} (\mathbf{E}^2 + \mathbf{B}^2) - \frac{1}{4\pi} \boldsymbol{\beta} \cdot (\mathbf{E} \times \mathbf{B}) \\ &= \frac{1}{8\pi} (\mathbf{E}^2 + \mathbf{B}^2) - \frac{1}{4\pi} (\boldsymbol{\beta} \times \mathbf{E}) \cdot \mathbf{B} \\ &= \frac{1}{8\pi} (\mathbf{E}^2 - \mathbf{B}^2) \end{aligned}$$

a Lorentz invariant. Thus the energy in K is given by

$$cP_e^0 = \gamma \int \frac{(\mathbf{E}^2 - \mathbf{B}^2)}{8\pi} d^3\sigma = \gamma^2 \int \frac{(\mathbf{E}^2 - \mathbf{B}^2)}{8\pi} d^3x \quad (17.45)$$

* One possible choice for K' is the "laboratory" where the observer is at rest. The discussion of the conservation laws in Chapter 6 may be interpreted in this way.

Similarly, the second equation in (17.41) becomes

$$c\mathbf{P}_e = \gamma\boldsymbol{\beta} \int \frac{(\mathbf{E}^2 - \mathbf{B}^2)}{8\pi} d^3\sigma = \gamma^2\boldsymbol{\beta} \int \frac{(\mathbf{E}^2 - \mathbf{B}^2)}{8\pi} d^3x \quad (17.46)$$

With the invariant integrand $(\mathbf{E}^2 - \mathbf{B}^2)$ it is clear that we have a 4-vector $P_e^\alpha = (\gamma m_e c, \gamma m_e \mathbf{v})$, where the electromagnetic mass is

$$m_e = \frac{1}{8\pi c^2} \int (\mathbf{E}^2 - \mathbf{B}^2) d^3\sigma = \frac{1}{8\pi c^2} \int \mathbf{E}^{(0)2} d^3x^{(0)}$$

in agreement with (17.43) and also (17.30) and (17.32).

The equation (17.45) for the energy has been used by Butler* to discuss the Trouton-Noble experiment, a test of special relativity involving the question of a torque on a charged suspended capacitor moving with respect to the ether.

It is perhaps instructive to examine the terms in the expression for \mathbf{P}_e to see the factor $\frac{4}{3}$ and its removal. Writing the first term of the momentum in (17.41),

$$c\mathbf{P}_e^{(1)} = \gamma \int c\mathbf{g} d^3\sigma \quad (17.47)$$

we find

$$c\mathbf{P}_e^{(1)} = \frac{\gamma}{4\pi} \int [\mathbf{E}^2\boldsymbol{\beta} - (\boldsymbol{\beta} \cdot \mathbf{E})\mathbf{E}] d^3\sigma \quad (17.48)$$

In the nonrelativistic limit, \mathbf{E} changes from its value in the rest frame only by terms of the order of β^2 . Assuming that the field is spherically symmetric in the rest frame, the second term averages to $\frac{1}{3}$ of the first on integrating over angles. One then has a numerical coefficient $(\frac{3}{5})/4\pi = (\frac{4}{3})/8\pi$, or $\mathbf{P}_e^{(1)} \approx 4m_e \mathbf{v}/3$. The contribution from the Maxwell stress tensor in (17.41) can be written

$$c\mathbf{P}_e^{(2)} = \frac{\gamma}{4\pi} \int [(\boldsymbol{\beta} \cdot \mathbf{E})\mathbf{E} - \frac{1}{2}(\mathbf{E}^2 + \mathbf{B}^2)\boldsymbol{\beta}] d^3\sigma \quad (17.49)$$

In the nonrelativistic limit and with the assumption of spherical symmetry in the rest frame, $\mathbf{P}_e^{(2)} \approx -m_e \mathbf{v}/3$, giving the proper sum. Much more significant, however, is the fact that *without any assumptions or approximations* $\mathbf{P}_e^{(1)} + \mathbf{P}_e^{(2)}$ add to give (17.46), the correct 3-vector momentum to go with the energy (17.45) to form an energy-momentum 4-vector for electrostatic rest-frame fields.

The lack of covariance of the Abraham-Lorentz model has been overcome by means of the properly covariant expression (17.40) for the electromagnetic 4-momentum. This seems to have first been done by Kwal† and later by Rohrlich‡ who gives a thorough discussion in his book cited in the bibliography. A closely related relativistic discussion of the incorrect factor of $\frac{4}{3}$ in the

Abraham-Lorentz force equation was given by Fermi* in 1922 when he demonstrated that a covariant application of Hamilton's principle leads to an appropriate modification of the self-force (17.20) so that a factor of unity is obtained, instead of $\frac{4}{3}$. A treatment similar in some respects to that given here is presented by Wilson.†

17.6 Integrodifferential Equation of Motion, Including Radiation Damping

In Section 17.2 the Abraham-Lorentz equation (17.9) was discussed qualitatively. It was pointed out that, if the radiative effects were considered as small in some sense, a scheme of successive approximations could be used to describe the motion. Nevertheless, the equation in its differential form contains unphysical behavior [e.g., solution (17.10)] because it is higher order in time differentiation than a mechanical equation of motion should be. It is desirable to have an equivalent equation of motion which is of the correct order, has no grossly unphysical solutions, and exhibits the successive approximations aspect in a natural manner. The discussion will be limited to nonrelativistic motion, although the generalization to fully relativistic motion is not difficult.

The guiding principle in converting (17.9) into an equivalent equation of motion is that the new equation should have solutions which evolve continuously into those for a neutral particle in the limit as the charge of the particle tends to zero. The smaller the particle's charge, the smaller the self-fields, and the smaller the radiative effects, other things being equal.

If the external force is thought of as a given function of time, (17.9) can be integrated once with respect to time by use of an integrating factor. We put

$$\dot{\mathbf{v}}(t) = e^{t/\tau} \mathbf{u}(t)$$

Then we find from (17.9) that

$$m\dot{\mathbf{u}} = -\frac{1}{\tau} e^{-t/\tau} \mathbf{F}(t)$$

The first integral is therefore

$$m\dot{\mathbf{v}}(t) = \frac{e^{t/\tau}}{\tau} \int_1^C e^{-t'/\tau} \mathbf{F}(t') dt' \quad (17.50)$$

The minus sign of the preceding line has been absorbed by making the lower limit of the integral the indefinite one. The constant of integration C is to be determined on physical grounds.

* E. Fermi, *Z. Physik* **24**, 340 (1922), or *Atti accad. nazl. Lincei Rend.* **31**, 184, 306 (1922).

† W. Wilson, *Proc. Phys. Soc. (London)* **A48**, 376 (1936).

The integrodifferential equation of motion (17.50) differs from customary mechanical equations of motion in that the acceleration of the particle at any time depends, not on the instantaneous value of the force acting, but on a weighted time average of the force. The presence of the factor $e^{-(t'-t)/\tau}$ means that only a small time interval of order τ is involved. Since $\tau \propto e^2$, that time interval becomes vanishingly small as $e^2 \rightarrow 0$. Then we demand that the equation of motion become the Newton equation, $m\dot{\mathbf{v}}(t) = \mathbf{F}(t)$. This is accomplished by choosing the upper limit on the integral in (17.50) as infinity. To see the behavior in detail, we introduce a new variable of integration,

$$s = \frac{1}{\tau} (t' - t)$$

Then (17.50) can be written

$$m\dot{\mathbf{v}}(t) = \int_0^\infty e^{-s} \mathbf{F}(t + \tau s) ds \quad (17.51)$$

If the force is slowly varying in time (measured in units of τ), a Taylor series expansion around $s=0$ can be expected to converge rapidly. Thus we write

$$\mathbf{F}(t + \tau s) = \sum_{n=0}^{\infty} \frac{(\tau s)^n}{n!} \frac{d^n \mathbf{F}(t)}{dt^n} \quad (17.52)$$

On substitution into (17.51) this gives

$$m\dot{\mathbf{v}}(t) = \sum_{n=0}^{\infty} \tau^n \frac{d^n \mathbf{F}(t)}{dt^n} \quad (17.53)$$

In the limit $\tau \rightarrow 0$ only the $n=0$ term in the series survives. Then one has the ordinary equation of motion of an uncharged particle. The higher terms represent radiative corrections for a charged particle, terms which are important only if the force varies in time sufficiently rapidly.

The integrodifferential equation (17.51) can be regarded as a physically reasonable replacement for the Abraham-Lorentz equation of motion (17.9). All solutions of (17.51) satisfy (17.9). But unphysical "runaway" solutions, such as (17.10), do not occur. Equation (17.51) still has certain peculiarities. The chief of these is its violation of the traditional concept of causality. It is evident from (17.51) that the acceleration at time t depends on the force acting at times *later* than t . This is contrary to our ideas of cause and effect. Figure 17.1 shows a typical example of such acausal behavior. A constant force is applied to the particle for times $t > 0$. The equation of motion predicts "preacceleration" before the force is "actually" applied.

To understand whether such effects are in contradiction to known facts we must consider the time scale involved. The acausal effects are limited to time intervals of the order of $\tau \sim e^2/mc^3 \sim 10^{-24}$ sec. This is the time it takes light to travel a distance of the order of the "size" of elementary particles. Such a short

Fig. 17.1 "Preacceleration" of charged particle.

time interval is impossible to detect by macroscopic means. Forces, for example, cannot be turned on and off at a particle with the rapidity indicated in the figure. Hence the lack of causality inherent in (17.51) cannot be observed in the laboratory. We describe this state of affairs by saying that, while (17.51) implies lack of microscopic causality, the model satisfies the requirements of macroscopic causality. Another important point is that the model is a classical one which surely fails at distances and times much greater than e^2/mc^2 and τ . As a consequence of the uncertainty principle the turning on of an external force in a time interval Δt is accompanied by uncertainties in energy of the order of $\Delta E \sim \hbar/\Delta t$. If these energy uncertainties are of the order of the rest energy mc^2 of the particle, the behavior will be far from classical. This sets a quantum-mechanical limit on the time intervals, $\tau_q \sim \hbar/mc^2 \sim 137\tau$. Since $\tau_q \gg \tau$, we reach the conclusion that in the domain where the classical equation is expected to hold the motions are sufficiently gentle that (1) acausal effects are of very minor importance, and (2) radiative reaction causes only small corrections to the motion.

If the applied force \mathbf{F} is given as a function of position rather than time, the solution of the integrodifferential equation becomes somewhat more involved, although no different in principle.

17.7 Line Breadth and Level Shift of an Oscillator

The effects of radiative reaction are of great importance in the detailed behavior of atomic systems. Although a complete discussion involves the rather elaborate formalism of quantum electrodynamics, the qualitative features are apparent from a classical treatment. As a typical example we consider a charged particle bound by a one-dimensional linear restoring force with force constant $k = m\omega_0^2$. In the absence of radiation damping the particle oscillates with constant amplitude at the characteristic frequency ω_0 . When the reactive effects are

included, the amplitude of oscillation gradually decreases, since energy of motion is being converted into radiant energy. This is the classical analogue of spontaneous emission in which an atom makes a transition from an excited state to a state of lower energy by emission of a photon.

If the displacement of the charged particle from equilibrium is $x(t)$, the equation of motion (17.51) for this problem is

$$\ddot{x}(t) + \omega_0^2 \int_0^\infty e^{-s} x(t+\tau s) ds = 0 \quad (17.54)$$

Since the solution when $\tau=0$ is $x(t) \sim e^{-i\omega_0 t}$, it is natural to assume a solution of the form,

$$x(t) = x_0 e^{-\alpha t} \quad (17.55)$$

We anticipate on physical grounds that the imaginary part of α will be closely equal to ω_0 , at least for $\omega_0 \tau \ll 1$, but that α will have a positive real part to describe the dissipative effect of the emission of radiation. When (17.55) is substituted into (17.54) it becomes

$$x_0 e^{-\alpha t} \left[\alpha^2 + \omega_0^2 \int_0^\infty e^{-(1+\alpha\tau)s} ds \right] = 0$$

The existence of the integral requires $\text{Re}(1+\alpha\tau) > 0$. With that proviso, we have α determined by a cubic equation,

$$\tau\alpha^3 + \alpha^2 + \omega_0^2 = 0 \quad (17.56)$$

This is the same cubic that emerges from (17.9), but we have the condition $\text{Re}(1+\alpha\tau) > 0$ to eliminate the “runaway” solution ($\alpha \approx -(1+\omega_0^2\tau^2)/\tau$). The two physically meaningful roots can be exhibited in closed form for arbitrary τ and ω_0 , but the formula is sufficiently involved that it is of little value except for numerical computation. We are interested in the range of parameters where $\omega_0 \tau \ll 1$. Then it is a simple matter to show directly from (17.56) that, correct to order $(\omega_0 \tau)^2$ inclusive, α is given by

$$\left. \begin{aligned} \alpha &= \frac{\Gamma}{2} \pm i(\omega_0 + \Delta\omega) \\ \Gamma &= \omega_0^2 \tau \\ \Delta\omega &= -\frac{5}{8} \omega_0^3 \tau^2 \end{aligned} \right\} \quad (17.57)$$

where

The constant Γ is known as the *decay constant*, while $\Delta\omega$ is called the *level shift*.*

* The reader is invited to pause at this point and consider the decay constant Γ from various points of view. One is to use the Larmor power formula (17.6) and conservation of energy directly to relate the time-average radiated power $\bar{P}(t)$ to the total energy of the oscillator $E(t)$. Another is to ask for the initial energy and amplitude x_0 of the oscillator such that $\Gamma = \bar{P}/\hbar\omega_0$, corresponding to the emission of a single photon of energy $\hbar\omega_0$. These can then be compared to the values for a quantum-mechanical oscillator in its n th quantum state.

The energy of the oscillator decays exponentially as $e^{-\Gamma t}$ because of radiation damping. This means that the emitted radiation appears as a wave train with effective length of the order of c/Γ . Such a finite pulse of radiation is not exactly monochromatic but has a frequency spectrum covering an interval of order Γ . The exact shape of the frequency spectrum is given by the square of the Fourier transform of the electric field or the acceleration. Neglecting an initial transient (of duration τ), the amplitude of the spectrum is thus proportional to

$$E(\omega) \propto \int_0^\infty e^{-\alpha t} e^{i\omega t} dt = \frac{1}{\alpha - i\omega}$$

The energy radiated per unit frequency interval is therefore

$$\frac{dI(\omega)}{d\omega} = I_0 \frac{\Gamma}{2\pi} \frac{1}{(\omega - \omega_0 - \Delta\omega)^2 + (\Gamma/2)^2} \quad (17.58)$$

where I_0 is the total energy radiated. This spectral distribution is called a *resonant line shape*. The width of the distribution at half-maximum intensity is called the *half-width* or *line breadth* and is equal to Γ . Shown in Fig. 17.2 is such a spectral line. Because of the reactive effects of radiation the line is *broadened* and *shifted* in frequency.

The classical line breadth for electronic oscillators is a universal constant when expressed in terms of wavelength:

$$\Delta\lambda = 2\pi \frac{c}{\omega_0^2} \Gamma = 2\pi c\tau = 1.2 \times 10^{-4} \text{ \AA}$$

Quantum mechanically the natural widths of spectral lines vary. In order to establish a connection with the classical treatment, the quantum-mechanical line width is sometimes written as

$$\Gamma_a = f_{ij}\Gamma$$

Fig. 17.2 Broadening and shifting of spectral line because of radiative reaction. The resonant line shape has width Γ . The level shift is $\Delta\omega$.

where f_{ij} is the "oscillator strength" of the transition ($i \rightarrow j$). Oscillator strengths vary considerably, sometimes being nearly unity for strong single-electron transitions and sometimes much smaller.

The classical level shift $\Delta\omega$ is smaller than the line width Γ by a factor $\omega_0\tau \ll 1$. Quantum mechanically (and experimentally) this is not so. The reason is that in the quantum theory there is a different mechanism for the level shift, although still involving the electromagnetic field. Even in the absence of photons, the quantized radiation field has nonvanishing expectation values of the *squares* of the electromagnetic field strengths (vacuum fluctuations). These fluctuating fields (along with vacuum fluctuations in the negaton-positon field) act on the charged particle to cause a shift in its energy. The quantum-mechanical level shift for an oscillator is of the order of

$$\frac{\Delta\omega_q}{\omega_0} \sim \omega_0\tau \log\left(\frac{mc^2}{\hbar\omega_0}\right)$$

as compared to the classical shift due to emission of radiation,

$$\frac{|\Delta\omega_c|}{\omega_0} \sim (\omega_0\tau)^2$$

The quantum-mechanical level shift is seen to be comparable to, or greater than, the line width. The small radiative shift of energy levels of atoms was first observed by Lamb in 1947* and is called the *Lamb shift* in his honor. A readable account of the quantum-theoretical aspects of the problem, requiring only a rudimentary knowledge of quantum field theory, has been given by Weisskopf.†

17.8 Scattering and Absorption of Radiation by an Oscillator

The scattering of radiation by free charged particles has been discussed in Sections 14.7 and 14.8. We now wish to consider the scattering and absorption of radiation by bound charges. The first example chosen is the scattering of radiation of frequency ω by a single nonrelativistic particle of mass m and charge e bound by a spherically symmetric, linear, restoring force $m\omega_0^2\mathbf{x}$. Because we will be dealing with steady-state oscillations, it is allowable to employ the Abraham-Lorentz equation (17.9), rather than the integrodifferential form (17.51). Then the equation of motion is

$$m(\ddot{\mathbf{x}} - \tau\ddot{\dot{\mathbf{x}}} + \omega_0^2\mathbf{x}) = \mathbf{F}(t)$$

If we wish to allow for other dissipative processes (corresponding quantum-mechanically to other modes of decay besides photon re-emission), we can add a resistive term ($m\Gamma'\dot{\mathbf{x}}$) to the left-hand side, Γ' being a decay constant with

* W. E. Lamb and R. C. Retherford, *Phys. Rev.* **72**, 241 (1947).

† V. F. Weisskopf, *Revs. Modern Phys.*, **21**, 305 (1949).

dimensions of frequency. The incident electromagnetic field provides the driving force. In the dipole approximation the equation of motion then becomes

$$\ddot{\mathbf{x}} + \Gamma' \dot{\mathbf{x}} - \tau \ddot{\mathbf{x}} + \omega_0^2 \mathbf{x} = \frac{e}{m} \epsilon E_0 e^{-i\omega t} \quad (17.59)$$

where E_0 is the electric field at the center of force, and ϵ is the incident polarization vector. The steady-state solution is

$$\mathbf{x} = \frac{e}{m} \frac{E_0 e^{-i\omega t}}{\omega_0^2 - \omega^2 - i\omega \Gamma_t} \epsilon \quad (17.60)$$

where

$$\Gamma_t(\omega) = \Gamma' + \left(\frac{\omega}{\omega_0}\right)^2 \Gamma \quad (17.61)$$

is called the *total decay constant* or *total width*. The radiative decay constant is $\Gamma = \omega_0^2 \tau$.

The accelerated motion described by (17.60) gives rise to radiation fields. From (14.18) the radiation electric field is

$$\mathbf{E}_{\text{rad}} = \frac{e}{c^2} \frac{1}{r} [\mathbf{n} \times (\mathbf{n} \times \ddot{\mathbf{x}})]_{\text{ret}}$$

Consequently the radiation field with polarization ϵ' is given by

$$\epsilon'^* \cdot \mathbf{E}_{\text{rad}} = \frac{e^2}{mc^2} \omega^2 \frac{E_0 e^{-i\omega t} e^{ikr}}{\omega_0^2 - \omega^2 - i\omega \Gamma_t} \left(\frac{\epsilon'^* \cdot \epsilon}{r} \right) \quad (17.62)$$

From definition (14.101) of differential scattering cross section we find that the cross section for scattered radiation of frequency ω and polarization ϵ' is

$$\frac{d\sigma(\omega, \epsilon')}{d\Omega} = \left| \frac{\epsilon'^* \cdot \mathbf{E}_{\text{rad}}}{E_0} \right|^2 = \left(\frac{e^2}{mc^2} \right)^2 |\epsilon'^* \cdot \epsilon|^2 \left[\frac{\omega^4}{(\omega_0^2 - \omega^2)^2 + \omega^2 \Gamma_t^2} \right] \quad (17.63)$$

The factor multiplying the square bracket is just the Thomson cross section for scattering by a free particle.

For frequencies very small compared to the binding frequency ($\omega \ll \omega_0$) the cross section reduces to

$$\frac{d\sigma(\omega, \epsilon')}{d\Omega} = \left(\frac{e^2}{mc^2} \right)^2 |\epsilon'^* \cdot \epsilon|^2 \left(\frac{\omega}{\omega_0} \right)^4 \quad (17.64)$$

The scattering at long wavelengths is thus inversely proportional to the fourth power of the wavelength. This is the Rayleigh law of scattering, already seen in Chapters 9 and 16 for scattering at long wavelengths.

For frequencies near the binding frequency ω_0 the scattering becomes very great, showing a typical resonance behavior. In the neighborhood of the resonance the cross section can be approximated by

$$\frac{d\sigma(\omega, \epsilon')}{d\Omega} \approx \frac{9}{16} \lambda_0^2 \frac{\Gamma^2}{(\omega - \omega_0)^2 + (\Gamma/2)^2} |\epsilon'^* \cdot \epsilon|^2 \quad (17.65)$$

where $\lambda_0 = (c/\omega_0)$ is the wavelength (divided by 2π) at resonance, $\Gamma = \omega_0^2 \tau$ is the radiative decay constant, and $\Gamma_t = \Gamma + \Gamma'$. If a sum is taken over scattered polarizations and an integration is made over all angles, there results a total scattering cross section,

$$\sigma_{sc}(\omega) \simeq \frac{3\pi}{2} \lambda_0^2 \frac{\Gamma^2}{(\omega - \omega_0)^2 + (\Gamma_t/2)^2} \quad (17.66)$$

This exhibits the typical resonant line shape with half-width given by Γ_t and peak cross section,

$$\sigma_{sc}(\omega_0) = 6\pi \lambda_0^2 \left(\frac{\Gamma}{\Gamma_t}\right)^2 \quad (17.67)$$

At high frequencies ($\omega \gg \omega_0$) the cross section (17.63) approaches the Thomson free-particle value, apart from a factor $(1 + \omega^2 \tau^2)^{-1}$ due to radiation damping. In the classical domain this factor can be taken as unity: $\omega \tau \sim 1$ corresponds to photons of energies $\hbar \omega \sim 137 mc^2$. Quantum effects become important when $\hbar \omega \sim mc^2$, as discussed in Sections 14.7 and 17.6.

Figure 17.3 shows the scattering cross section over the whole classical range of frequencies.

The sharply resonant scattering at $\omega = \omega_0$ is called *resonance fluorescence*. Quantum mechanically it corresponds to the absorption of radiation by an atom, molecule, or nucleus in a transition from its ground state to an excited state with the subsequent re-emission of the radiation in other directions in the process of de-excitation. The factor $6\pi \lambda_0^2$ in the peak cross section is replaced quantum mechanically by the statistical factor,

$$6\pi \lambda_0^2 \rightarrow 4\pi \lambda_0^2 \frac{(2J_{ex} + 1)}{2(2J_g + 1)}$$

where J_g and J_{ex} are the angular momenta of the ground and excited states, and $4\pi \lambda_0^2$ is the maximum allowable scattering for any single quantum state. The

Fig. 17.3 Total cross section for the scattering of radiation by an oscillator as a function of frequency. σ_T is the Thomson free-particle scattering cross section.

remaining factors represent a sum over all final magnetic substates and an average over initial ones, the factor 2 being the statistical weight associated with the incident radiation's polarizations. The classical result corresponds to $J_g = 0$ and $J_{ex} = 1$.

The absorption of radiation, as distinct from scattering, has already been discussed for an oscillator in Section 13.2. The driving fields there were those of a swift, charged particle, but the treatment [from equation (13.15) to (13.24)] was general enough to allow direct transcription. The only differences are that the Γ of Section 13.2 is to be replaced by Γ_i (17.61), and the incident electric field is to be taken as essentially monochromatic. From (13.24) we find that in the dipole approximation the energy absorbed per unit frequency interval is

$$\frac{dE}{d\omega} = \frac{e^2}{m} |E_0(\omega)|^2 \frac{2\omega^2\Gamma_i}{(\omega_0^2 - \omega^2)^2 + \omega^2\Gamma_i^2} \quad (17.68)$$

This energy is removed from the incident beam and converted into mechanical motion of the oscillator. Some of it is re-emitted. This is the scattering that we have just discussed. Some of it is dissipated in other ways, described schematically by the frictional term in (17.59). The latter is true absorption in the sense that we have used it in Section 16.9 and in Chapter 9. Since (17.68) represents the total of the scattering and nonradiative dissipation, it is appropriate to define the *total cross section* as the energy (17.68) absorbed per unit frequency interval divided by the incident energy per unit area per unit frequency. The incident flux is $(c/2\pi) |E_0(\omega)|^2$. Consequently the total cross section is

$$\sigma_t(\omega) = 4\pi \frac{e^2}{mc} \frac{\omega^2\Gamma_i}{(\omega_0^2 - \omega^2)^2 + \omega^2\Gamma_i^2} \quad (17.69)$$

Using the definition of $\Gamma = \omega_0^2\tau$, this can be written

$$\sigma_t(\omega) = 6\pi\lambda_0^2 \frac{\omega^2\Gamma\Gamma_i}{(\omega_0^2 - \omega^2)^2 + \omega^2\Gamma_i^2} \quad (17.70)$$

In the three regions, $\omega \ll \omega_0$, $\omega \sim \omega_0$, $\omega \gg \omega_0$, the cross section can be approximated as

$$\sigma_t(\omega) \approx \begin{cases} 6\pi\lambda_0^2 \frac{\omega^2\Gamma\Gamma_i}{\omega_0^4}, & \omega \ll \omega_0 \\ \frac{3\pi}{2} \lambda_0^2 \frac{\Gamma\Gamma_i}{(\omega_0 - \omega)^2 + (\Gamma_i/2)^2}, & \omega \approx \omega_0 \\ 6\pi\lambda_0^2 \frac{\Gamma\Gamma_i}{\omega^2}, & \omega \gg \omega_0 \end{cases} \quad (17.71)$$

We see that near the resonant frequency ω_0 the total cross section has the same resonant shape as the scattering cross section, but is larger by a factor Γ_i/Γ . At high frequencies $\Gamma_i \rightarrow \omega^2\tau$, so that the total cross section approaches the constant Thomson value (we have again ignored $\omega\tau$ compared to unity).

The difference between the total cross section and the scattering cross section is the absorption cross section, sometimes called the *reaction cross section* $\sigma_r(\omega)$. All three cross sections can be written in a suggestive form based on (17.70):

$$\left. \begin{array}{l} \sigma_{sc}(\omega) \\ \sigma_r(\omega) \\ \sigma_t(\omega) \end{array} \right\} = 6\pi c^2 \frac{(\omega^2/\omega_0^2)\Gamma}{(\omega_0^2 - \omega^2)^2 + \omega^2\Gamma_t^2} \left\{ \begin{array}{l} \frac{\omega^2}{\omega_0^2}\Gamma \\ \Gamma' \\ \Gamma_t \end{array} \right. \quad (17.72)$$

The resonant denominator is the same for all three cross sections. The radiative process is proportional to $(\omega^2/\omega_0^2)\Gamma = \omega^2\tau$. The other dissipative processes (reactions) are proportional to Γ' . The common factor $(\omega^2/\omega_0^2)\Gamma$ represents the incident radiation. For scattering a second factor $(\omega^2/\omega_0^2)\Gamma$ appears, while for reactions a factor Γ' appears. The total cross section involves the total width Γ_t . This characteristic product of decay constants or widths appropriate to the initial and final states of the process also occurs quantum mechanically in the theory of resonance reactions.

The integral over all frequencies of the total cross section yields a relation called the *dipole sum rule*. Radiation damping effects are neglected. This is necessary if we are to have causal behavior. The unphysical root of the cubic equation (17.56) has its counterpart here in a pole of (17.62) in the complex ω plane far from the origin in the upper half plane at $\omega \approx i/\tau$. In an integral over all frequencies this unphysical pole contributes importantly and erroneously. Neglect of radiative reaction effects is equivalent to the assumption that the width Γ_t in (17.70) is a constant, independent of frequency. The integral of $\sigma_t(\omega)$ over all frequencies in this approximation is then easily shown to be

$$\int_0^\infty \sigma_t(\omega) d\omega = \frac{2\pi^2 e^2}{mc} \quad (17.73)$$

We note that the sum rule depends on the charge and mass of the particle, but not on other detailed properties, such as ω_0 and Γ' . It is equivalent to expression (13.26) for the total energy absorbed by the system from the passing fields. It is also equivalent to the Kramers-Kronig sum rule (7.122) for the plasma frequency ($\omega \text{ Im } \epsilon(\omega) = cN\sigma_t$).

As can be inferred from its connection to the Kramers-Kronig dispersion relations, the dipole sum rule is a general statement that is true both classically and quantum mechanically, no matter how complicated the response of the system to the incident radiation as a function of frequency. It depends only on the three physical requirements that (a) the dipole approximation applies, (b) the normal modes of oscillation of the system must decay in time (even if very slowly) because of ever-present resistive losses, and (c) at high frequencies binding effects are unimportant and the particle responds as if it were free (see Problem 17.8).

For a system of independent particles with charges e_i and masses m_i bound to a fixed center the sum rule has an obvious generalization,

$$\int_0^\infty \sigma_i(\omega) d\omega = \frac{2\pi^2}{c} \sum_i \frac{e_i^2}{m_i} \quad (17.74)$$

If the particles are bound together by mutual interactions, the center of mass motion must be removed. It is easy to show that this is accomplished by subtracting from the sum in (17.74) a term (Q^2/M) , where Q is the total charge of the system of particles and M the total mass. For a nucleus with Z protons and $N (= A - Z)$ neutrons, the sum rule then becomes

$$\int_0^\infty \sigma_i(\omega) d\omega = \frac{2\pi^2 e^2}{mc} \left(\frac{NZ}{A} \right) \quad (17.75)$$

where e is the protonic charge, and m is the mass of one nucleon.*

The Lorentz-Dirac theory is discussed in
Barut,
Rohrlich,

where other aspects of relativistic classical field theory are treated in detail.

The integrodifferential equation of motion (17.51) seems to have been first written down by

Iwanenko and Sokolow, Section 35.

Examples of the solution of the integrodifferential equation of motion are given by
G. N. Plass, *Revs. Modern Phys.*, **33**, 37 (1961).

* Actually the sum rule for the nuclear photoeffect has an added factor $(1+x)$, where $x \sim \frac{1}{2}$ is the contribution due to exchange forces in the nucleus. A physical way to understand this increase is to think of the exchange forces as caused by the transfer of virtual charged pi mesons between nucleons. These virtual charged mesons contribute to the total nuclear current. Since their e/m ratio is larger than that of the nucleons, they cause an increase of the sum rule over its ordinary value (17.75).

PROBLEMS

17.1 A nonrelativistic particle of charge e and mass m is bound by a linear, isotropic, restoring force with force constant $m\omega_0^2$.

Using (17.13) and (17.16) of Section 17.2, show that the energy and angular momentum of the particle both decrease exponentially from their initial values as $e^{-\Gamma t}$, where $\Gamma = \omega_0^2 \tau$.

17.2 A nonrelativistic electron of charge $-e$ and mass m bound in an attractive Coulomb potential $(-Ze^2/r)$ moves in a circular orbit in the absence of radiation reaction.

(a) Show that both the energy and angular-momentum equations (17.13) and (17.16) lead to the solution for the slowly changing orbit radius,

$$r^3(t) = r_0^3 - 9Z(c\tau)^3 \frac{t}{\tau}$$

where r_0 is the value of $r(t)$ at $t=0$.

(b) For circular orbits in a Bohr atom the orbit radius and the principal quantum number n are related by $r = n^2 a_0 / Z$. If the transition probability for transitions from $n \rightarrow (n-1)$ is defined as $-dn/dt$, show that the result of (a) agrees with that found in Problem 14.10.

(c) From (a) calculate the numerical value of the times taken for a mu meson of mass $m = 207m_e$ to fall from a circular orbit with principal quantum number $n_1 = 10$ to one with $n_2 = 4$, and $n_2 = 1$. These are reasonable estimates of the time taken for a mu meson to cascade down to its lowest orbit after capture by an isolated atom.

17.3 An electron moving in an attractive Coulomb field $(-Ze^2/r)$ with binding energy ϵ and angular momentum L has an elliptic orbit,

$$\frac{1}{r} = \frac{Ze^2 m}{L^2} \left[1 + \sqrt{1 - \frac{2\epsilon L^2}{Z^2 e^4 m}} \cos(\theta - \theta_0) \right]$$

The eccentricity ξ of the ellipse is given by the square root multiplying the cosine.

(a) By performing the appropriate time averages over the orbit show that the secular changes in energy and angular momentum are

$$\frac{d\epsilon}{dt} = \frac{2^{3/2}}{3} \frac{Z^3 e^8 m^{1/2}}{c^3} \frac{\epsilon^{3/2}}{L^5} \left(3 - \frac{2\epsilon L^2}{Z^2 e^4 m} \right)$$

$$\frac{dL}{dt} = -\frac{2^{5/2}}{3} \frac{Ze^4}{m^{1/2} c^3} \frac{\epsilon^{3/2}}{L^2}$$

(b) If the initial values of ϵ and L are ϵ_0 and L_0 , show that

$$\epsilon(L) = \frac{Z^2 e^4 m}{2L^2} \left[1 - \left(\frac{L}{L_0} \right)^3 \right] + \frac{\epsilon_0}{L_0} L$$

Calculate the eccentricity of the ellipse, and show that it decreases from its initial value as $(L/L_0)^{3/2}$, showing that the orbit tends to become circular as time goes on.

(c) Compare your results here to the special case of a circular orbit of Problem 17.2.

Hint: In performing the time averages make use of Kepler's law of equal areas ($dt = mr^2 d\theta/L$) to convert time integrals to angular integrals.

17.4 The Dirac (1938) relativistic theory of classical point electrons has as its equation of motion,

$$\frac{dp_\mu}{d\tau} = F_\mu^{\text{ext}} + F_\mu^{\text{rad}}$$

where p_μ is the particle's 4-momentum, τ is the particle's proper time, and F_μ^{rad} is the covariant generalization of the radiative reaction force (17.8).

Using the requirement that any force must satisfy $F_\mu p^\mu = 0$, show that

$$F_\mu^{\text{rad}} = \frac{2e^2}{3mc^3} \left[\frac{d^2 p_\mu}{d\tau^2} + \frac{p_\mu}{m^2 c^2} \left(\frac{dp_\nu}{d\tau} \frac{dp^\nu}{d\tau} \right) \right]$$

17.5 (a) Show that for relativistic motion in one dimension the equation of motion of Problem 17.4 can be written in the form,

$$\dot{p} - \frac{2e^2}{3mc^3} \left(\ddot{p} - \frac{p\dot{p}^2}{p^2 + m^2 c^2} \right) = \sqrt{1 + \frac{p^2}{m^2 c^2}} f(\tau)$$

where p is the momentum in the direction of motion, a dot means differentiation with respect to proper time, and $f(\tau)$ is the ordinary Newtonian force as a function of proper time.

(b) Show that the substitution of $p = mc \sinh y$ reduces the relativistic equation to the Abraham-Lorentz form (17.9) in y and τ . Write down the general solution for $p(\tau)$, with the initial condition that

$$p(\tau) = p_0 \quad \text{at} \quad \tau = 0$$

17.6 A nonrelativistic particle of charge e and mass m is accelerated in one-dimensional motion across a gap of width d by a constant electric field. The mathematical idealization is that the particle has applied to it an external force ma while its coordinates lies in the interval $(0, d)$. Without radiation damping the particle, having initial velocity v_0 , is accelerated uniformly for a time $T = (-v_0/\alpha) + \sqrt{(v_0^2/\alpha^2) + (2d/\alpha)}$, emerging at $x = d$ with a final velocity $v_1 = \sqrt{v_0^2 + 2\alpha d}$.

With radiation damping the motion is altered so that the particle takes a time T' to cross the gap and emerges with a velocity v'_1 .

(a) Solve the integrodifferential equation of motion, including damping, assuming T and T' large compared to τ . Sketch a velocity versus time diagram for the motion with and without damping.

(b) Show that to lowest order in τ ,

$$T' = T - \tau \left(1 - \frac{v_0}{v_1} \right)$$

$$v'_1 = v_1 - \frac{\alpha^2 \tau}{v_1} T$$

(c) Verify that the sum of the energy radiated and the change in the particle's kinetic energy is equal to the work done by the applied field.

17.7 A classical model for the description of collision broadening of spectral lines is that the oscillator is interrupted by a collision after oscillating for a time T so that the coherence of the wave train is lost.

(a) Taking the oscillator used in Section 17.7 and assuming that the probability that a collision will occur between time T and $(T + dT)$ is $(\nu e^{-\nu T} dT)$, where ν is the mean

collision frequency, show that the averaged spectral distribution is:

$$\frac{dI(\omega)}{d\omega} = \frac{I_0}{2\pi} \frac{\Gamma + 2\nu}{(\omega - \omega_0)^2 + \left(\frac{\Gamma}{2} + \nu\right)^2}$$

so that the breadth of the line is $(2\nu + \Gamma)$.

(b) For the sodium doublet at 5893 \AA the oscillator strength is $f = 0.975$, so that the natural width is essentially the classical value, $\Delta\lambda = 1.2 \times 10^{-4} \text{ \AA}$. Estimate the Doppler width of the line, assuming the sodium atoms are in thermal equilibrium at a temperature of 500°K , and compare it with the natural width. Assuming a collision cross section of 10^{-16} cm^2 , determine the collision breadth of the sodium doublet as a function of the pressure of the sodium vapor. For what pressure is the collision breadth equal to the natural breadth? The Doppler breadth?

17.8 A single particle oscillator under the action of an applied electric field $\mathbf{E}_0 e^{-i\omega t}$ has a dipole moment given by

$$\mathbf{p} = \alpha(\omega) \mathbf{E}_0 e^{-i\omega t}$$

(a) Show that the total dipole cross section can be written as

$$\sigma_t(\omega) = \frac{2\pi}{c} [-i\omega\alpha(\omega) + \text{c.c.}]$$

(b) Using only the facts that all the normal modes of oscillation must have some damping and that the polarizability $\alpha(\omega)$ must approach the free-particle value $(-e^2/m\omega^2)$ at high frequencies, show that the cross section satisfies the dipole sum rule,

$$\int_0^\infty \sigma_t(\omega) d\omega = \frac{2\pi^2 e^2}{mc}$$

(The discussion of Kramers-Kronig dispersion relations in Chapter 7 is clearly relevant.)

Appendix on Units and Dimensions

The question of units and dimensions in electricity and magnetism has exercised a great number of physicists and engineers over the years. This situation is in marked contrast with the almost universal agreement on the basic units of length (centimeter or meter), mass (gram or kilogram), and time (mean solar second). The reason perhaps is that the mechanical units were defined when the idea of “absolute” standards was a novel concept (just before 1800), and they were urged on the professional and commercial world by a group of scientific giants (Borda, Laplace, and others). By the time the problem of electromagnetic units arose there were (and still are) many experts. The purpose of this appendix is to add as little heat and as much light as possible without belaboring the issue.

1 Units and Dimensions, Basic Units and Derived Units

The *arbitrariness* in the *number* of fundamental units and in the *dimensions* of any physical quantity in terms of those units has been emphasized by Abraham, Planck, Bridgman,* Birge,† and others. The reader interested in units as such will do well to familiarize himself with the excellent series of articles by Birge.

The desirable features of a system of units in any field are convenience and clarity. For example, theoretical physicists active in relativistic quantum field theory and the theory of elementary particles find it convenient to *choose* the universal constants such as Planck’s quantum of action and the velocity of light in vacuum to be *dimensionless* and of *unit magnitude*. The resulting system of units (called “natural” units) has only *one* basic unit, customarily chosen to be length. All quantities, whether length or time or force or energy, etc., are

* P. W. Bridgman, *Dimensional Analysis*, Yale University Press (1931).

† R. T. Birge, *Am. Phys. Teacher* (now *Am. J. Phys.*), **2**, 41 (1934); **3**, 102, 171 (1935).

expressed in terms of this one unit and have dimensions which are powers of its dimension. There is nothing contrived or less fundamental about such a system than one involving the meter, the kilogram, and the second as basic units. It is merely a matter of convenience.*

A word needs to be said about basic units or standards, considered as independent quantities, and derived units or standards, which are defined in both magnitude and dimension through theory and experiment in terms of the basic units. Tradition requires that mass (m), length (l), and time (t) be treated as basic. But for electrical quantities there has been no compelling tradition. Consider, for example, the unit of current. The “international” ampere (for a long period the accepted practical unit of current) is defined in terms of the mass of silver deposited per unit time by electrolysis in a standard silver voltameter. Such a unit of current is properly considered a basic unit, independent of the mass, length and time units, since the amount of current serving as the unit is found from a supposedly reproducible experiment in electrolysis.

On the other hand, the presently accepted standard of current, the “absolute” ampere, is defined as that current which when flowing in each of two infinitely long, parallel wires of negligible cross-sectional area, separated by a distance of 1 meter in vacuum, causes a transverse force per unit length of 2×10^{-7} newton/meter to act between the wires. This means that the “absolute” ampere is a derived unit, since its definition is in terms of the mechanical force between two wires through equation (A.4) below.† The “absolute” ampere is, by this definition, exactly one-tenth of the em unit of current, the abampere. Since 1948 the internationally accepted system of electromagnetic standards has been based on the meter, the kilogram, the second, and the above definition of the “absolute” ampere plus other derived units for resistance, voltage, etc. This seems to be a desirable state of affairs. It avoids such difficulties as arose when, in 1894, by Act of Congress (based on recommendations of an international commission of engineers and scientists), independent basic units of current, voltage, and resistance were defined in terms of three independent experiments (silver voltameter, Clark standard cell, specified column of mercury).‡ Soon

* In quantum field theory, powers of the coupling constant play the role of other basic units in doing dimensional analysis.

† The proportionality constant k_2 in (A.4) is thereby given the magnitude $k_2 = 10^{-7}$ in the MKSA system. The *dimensions* of the “absolute” ampere, as distinct from its magnitude, depend on the dimensions assigned k_2 . In the conventional MKSA system of electromagnetic units, electric current (I) is arbitrarily chosen as a *fourth* basic dimension. Consequently charge has dimensions It , and k_2 has dimensions of $mI^{-2}t^{-2}$. If k_2 is taken to be dimensionless, then current has the dimensions $m^{1/2}l^{1/2}t^{-1}$. The question of whether a fourth basic dimension like current is introduced or whether electromagnetic quantities have dimensions given by powers (sometimes fractional) of the three basic mechanical dimensions is a purely subjective matter and has no fundamental significance.

‡ See, for example, F. A. Laws, *Electrical Measurements*, McGraw-Hill, New York (1917), pp. 705–706.

afterwards, because of systematic errors in the experiments outside the claimed accuracy, Ohm's law was no longer valid, by Act of Congress!

At the present time the *Système International* (SI) has mass defined in terms of the standard *kilogram* kept in Paris, length in terms of the *meter* as a certain number of wavelengths in vacuo of a certain atomic transition in the ^{86}Kr atom, and time in terms of the *second* being a certain integer number of periods of a hyperfine transition in ^{133}Cs . Because of the extremely high precision with which the velocity of light can be measured with stabilized lasers (actually the measurement of both the frequency and the wavelength of the same spectral line), it is likely that soon the definition of the meter will be in terms of the unit of time (^{133}Cs) and a defined value for the speed of light in vacuo (see the Introduction for the latest value of c).*

2 Electromagnetic Units and Equations

In discussing the units and dimensions of electromagnetism we will take as our starting point the traditional choice of length (l), mass (m), and time (t) as independent, basic dimensions. Furthermore, we will make the commonly accepted definition of current as the time rate of change of charge ($I = dq/dt$). This means that the dimension of the ratio of charge and current is that of time.† The continuity equation for charge and current densities then takes the form:

$$\nabla \cdot \mathbf{J} + \frac{\partial \rho}{\partial t} = 0 \quad (\text{A.1})$$

To simplify matters we will initially consider only electromagnetic phenomena in free space, apart from the presence of charges and currents.

The basic physical law governing electrostatics is Coulomb's law on the force between two point charges q and q' , separated by a distance r . In symbols this law is

$$F_1 = k_1 \frac{qq'}{r^2} \quad (\text{A.2})$$

The constant k_1 is a proportionality constant whose magnitude and dimensions *either* are determined by the equation if the magnitude and dimensions of the unit of charge have been specified independently *or* are chosen arbitrarily in

* For a discussion of the use of quantum phenomena to define standards, see the article on Quantum Metrology by B. W. Petley in J. Thewlis, ed., *Encyclopaedic Dictionary of Physics*, Supplementary Volume 4, pp. 354 ff, Pergamon, Oxford (1971).

† From the point of view of special relativity it would be more natural to give current the dimensions of charge divided by length. Then current density \mathbf{J} and charge density ρ would have the same dimensions and would form a "natural" 4-vector. This is the choice made in a modified Gaussian system (see the footnote (p. 820) for Table 4).

order to define the unit of charge. Within our present framework all that is determined at the moment is that the product $(k_1 qq')$ has the dimensions (ml^3t^{-2}) .

The electric field \mathbf{E} is a derived quantity, customarily defined to be the force per unit charge. A more general definition would be that the electric field be numerically proportional to the force per unit charge, with a proportionality constant which is a universal constant perhaps having dimensions such that the electric field is dimensionally different from force per unit charge. There is, however, nothing to be gained by this extra freedom in the definition of \mathbf{E} , since \mathbf{E} is the first derived field quantity to be defined. Only when we define other field quantities may it be convenient to insert dimensional proportionality constants in the definitions in order to adjust the dimensions and magnitude of these fields relative to the electric field. Consequently, with no significant loss of generality the electric field of a point charge q may be defined from (A.2) as the force per unit charge,

$$E = k_1 \frac{q}{r^2} \quad (\text{A.3})$$

All systems of units known to the author use this definition of electric field.

For steady-state magnetic phenomena Ampère's observations form a basis for specifying the interaction and defining the magnetic induction. According to Ampère, the force per unit length between two infinitely long, parallel wires separated by a distance d and carrying currents I and I' is,

$$\frac{dF_2}{dl} = 2k_2 \frac{II'}{d} \quad (\text{A.4})$$

The constant k_2 is a proportionality constant akin to k_1 in (A.2). The dimensionless number 2 is inserted in (A.4) for later convenience in specifying k_2 . Because of our choice of the dimensions of current and charge embodied in (A.1) the dimensions of k_2 relative to k_1 are determined. From (A.2) and (A.4) it is easily found that the ratio k_1/k_2 has the dimension of a velocity squared (l^2t^{-2}) . Furthermore, by comparison of the magnitude of the two mechanical forces (A.2) and (A.4) for known charges and currents, the magnitude of the ratio k_1/k_2 in free space can be found. The numerical value is closely given by the square of the velocity of light in vacuum. Therefore in symbols we can write

$$\frac{k_1}{k_2} = c^2 \quad (\text{A.5})$$

where c stands for the velocity of light in magnitude and dimension.

The magnetic induction \mathbf{B} is derived from the force laws of Ampère as being numerically proportional to the force per unit current with a proportionality constant α that may have certain dimensions chosen for convenience. Thus for a long straight wire carrying a current I , the magnetic induction \mathbf{B} at a distance d

has the magnitude (and dimensions)

$$B = 2k_2\alpha \frac{I}{d} \quad (\text{A.6})$$

The dimensions of the ratio of electric field to magnetic induction can be found from (A.1), (A.3), (A.5), and (A.6). The result is that (E/B) has the dimensions $(l/t\alpha)$.

The third and final relation in the specification of electromagnetic units and dimensions is Faraday's law of induction, which connects electric and magnetic phenomena. The observed law that the electromotive force induced around a circuit is proportional to the rate of change of magnetic flux through it takes on the differential form,

$$\nabla \times \mathbf{E} + k_3 \frac{\partial \mathbf{B}}{\partial t} = 0 \quad (\text{A.7})$$

where k_3 is a constant of proportionality. Since the dimensions of \mathbf{E} relative to \mathbf{B} are established, the dimensions of k_3 can be expressed in terms of previously defined quantities merely by demanding that both terms in (A.7) have the same dimensions. Then it is found that k_3 has the dimensions of α^{-1} . Actually, k_3 is equal to α^{-1} . This is established on the basis of Galilean invariance in Section 6.1. But the easiest way to prove the equality is to write all the Maxwell equations in terms of the fields defined here:

$$\left. \begin{aligned} \nabla \cdot \mathbf{E} &= 4\pi k_1 \rho \\ \nabla \times \mathbf{B} &= 4\pi k_2 \alpha \mathbf{J} + \frac{k_2 \alpha}{k_1} \frac{\partial \mathbf{E}}{\partial t} \\ \nabla \times \mathbf{E} + k_3 \frac{\partial \mathbf{B}}{\partial t} &= 0 \\ \nabla \cdot \mathbf{B} &= 0 \end{aligned} \right\} \quad (\text{A.8})$$

Then for source-free regions the two curl equations can be combined into the wave equation,

$$\nabla^2 \mathbf{B} - k_3 \frac{k_2 \alpha}{k_1} \frac{\partial^2 \mathbf{B}}{\partial t^2} = 0 \quad (\text{A.9})$$

The velocity of propagation of the waves described by (A.9) is related to the combination of constants appearing there. Since this velocity is known to be that of light, we may write

$$\frac{k_1}{k_3 k_2 \alpha} = c^2 \quad (\text{A.10})$$

Combining (A.5) with (A.10), we find

$$k_3 = \frac{1}{\alpha} \quad (\text{A.11})$$

and equality holding for both magnitude and dimensions.

3 Various Systems of Electromagnetic Units

The various systems of electromagnetic units differ in their choices of the magnitudes and dimensions of the various constants above. Because of relations (A.5) and (A.11) there are only two constants (e.g., k_1 , k_3) that can (and must) be chosen arbitrarily. It is convenient, however, to tabulate all four constants (k_1 , k_2 , α , k_3) for the commoner systems of units. These are given in Table 1. We note that, apart from dimensions, the em units and MKSA units are very similar, differing only in various powers of 10 in their mechanical and electromagnetic units. The Gaussian and Heaviside-Lorentz systems differ only by factors of 4π . Only in the Gaussian (and Heaviside-Lorentz) system does k_3 have dimensions. It is evident from (A.7) that, with k_3 having dimensions of a reciprocal velocity, \mathbf{E} and \mathbf{B} have the same dimensions. Furthermore, with $k_3 = c^{-1}$, (A.7) shows that for electromagnetic waves in free space \mathbf{E} and \mathbf{B} are equal in magnitude as well.

Only electromagnetic fields in free space have been discussed so far. Consequently only the two fundamental fields \mathbf{E} and \mathbf{B} have appeared. There remains the task of defining the macroscopic field variables \mathbf{D} and \mathbf{H} . If the averaged electromagnetic properties of a material medium are described by a macroscopic polarization \mathbf{P} and a magnetization \mathbf{M} , the general form of the definitions of \mathbf{D} and \mathbf{H} are

$$\left. \begin{aligned} \mathbf{D} &= \epsilon_0 \mathbf{E} + \lambda \mathbf{P} \\ \mathbf{H} &= \frac{1}{\mu_0} \mathbf{B} - \lambda' \mathbf{M} \end{aligned} \right\} \quad (\text{A.12})$$

where ϵ_0 , μ_0 , λ , λ' are proportionality constants. Nothing is gained by making \mathbf{D} and \mathbf{P} or \mathbf{H} and \mathbf{M} have different dimensions. Consequently λ and λ' are chosen as pure numbers ($\lambda = \lambda' = 1$ in rationalized systems, $\lambda = \lambda' = 4\pi$ in unrationalized systems). But there is the choice as to whether \mathbf{D} and \mathbf{P} will differ in dimensions from \mathbf{E} , and \mathbf{H} and \mathbf{M} differ from \mathbf{B} . This choice is made for convenience and simplicity, usually in order to make the macroscopic Maxwell equations have a relatively simple, neat form. Before tabulating the choices made for different systems, we note that for linear, isotropic media the constitutive relations are always written

$$\left. \begin{aligned} \mathbf{D} &= \epsilon \mathbf{E} \\ \mathbf{B} &= \mu \mathbf{H} \end{aligned} \right\} \quad (\text{A.13})$$

Thus in (A.12) the constants ϵ_0 and μ_0 are the vacuum values of ϵ and μ . The relative permittivity of a substance (often called the *dielectric constant*) is defined as the dimensionless ratio (ϵ/ϵ_0), while the relative permeability (often called the *permeability*) is defined as (μ/μ_0).

Table 2 displays the values of ϵ_0 and μ_0 , the defining equations for \mathbf{D} and \mathbf{H} , the macroscopic forms of the Maxwell equations, and the Lorentz force equation

Table 1
Magnitudes and Dimensions of the Electromagnetic Constants for Various Systems of Units

The dimensions are given after the numerical values. The symbol c stands for the velocity of light in vacuum ($c = 2.998 \times 10^{10}$ cm/sec $= 2.998 \times 10^8$ m/sec). The first four systems of units use the centimeter, gram, and second as their fundamental units of length, mass, and time (l, m, t). The MKSA system uses the meter, kilogram, and second, plus current (I) as a fourth dimension, with the ampere as unit.

System	k_1	k_2	α	k_3
Electrostatic (esu)	1	$c^{-2}(t^2 l^{-2})$	1	1
Electromagnetic (emu)	$c^2(l^2 t^{-2})$	1	1	1
Gaussian	1	$c^{-2}(t^2 l^{-2})$	$c(l t^{-1})$	$c^{-1}(t l^{-1})$
Heaviside-Lorentz	$\frac{1}{4\pi}$	$\frac{1}{4\pi c^2}(t^2 l^{-2})$	$c(l t^{-1})$	$c^{-1}(t l^{-1})$
Rationalized MKSA	$\frac{1}{4\pi\epsilon_0} = 10^{-7} c^2$ $(m l^3 t^{-4} I^{-2})$	$\frac{\mu_0}{4\pi} \equiv 10^{-7}$ $(m l t^{-2} I^{-2})$	1	1

in the five common systems of units of Table 1. For each system of units the continuity equation for charge and current is given by (A.1), as can be verified from the first pair of the Maxwell equations in the table in each case.* Similarly, in all systems the statement of Ohm's law is $\mathbf{J} = \sigma \mathbf{E}$, where σ is the conductivity.

4 Conversion of Equations and Amounts between Gaussian Units and MKSA Units

The two systems of electromagnetic units in most common use today are the Gaussian and rationalized MKSA systems. The MKSA system has the virtue of overall convenience in practical, large-scale phenomena, especially in engineering applications. The Gaussian system is more suitable for microscopic problems involving the electrodynamics of individual charged particles, etc. Since microscopic, relativistic problems are important in this book, it has been found most convenient to use Gaussian units throughout. In Chapter 8 on wave guides and cavities an attempt has been made to placate the engineer by writing each key

* Some workers employ a modified Gaussian system of units in which current is defined by $I = (1/c)(dq/dt)$. Then the current density \mathbf{J} in the table must be replaced by $c\mathbf{J}$, and the continuity equation is $\nabla \cdot \mathbf{J} + (1/c)(\partial \rho / \partial t) = 0$. See also the footnote below Table 4.

Table 2

Definitions of ϵ_0 , μ_0 , D , H , Macroscopic Maxwell Equations, and Lorentz Force Equation in Various Systems of Units

Where necessary the dimensions of quantities are given in parentheses. The symbol c stands for the velocity of light in vacuum with dimensions (lt^{-1}) .

System	ϵ_0	μ_0	D, H	Macroscopic Maxwell Equations	Lorentz Force per Unit charge
Electrostatic (esu)	1	c^{-2} (t^2l^{-2})	$D = E + 4\pi P$ $H = c^2B - 4\pi M$	$\nabla \cdot D = 4\pi\rho$ $\nabla \times H = 4\pi J + \frac{\partial D}{\partial t}$ $\nabla \times E + \frac{\partial B}{\partial t} = 0$ $\nabla \cdot B = 0$	$E + v \times B$
Electromagnetic (emu)	c^{-2} (t^2l^{-2})	1	$D = \frac{1}{c^2}E + 4\pi P$ $H = B - 4\pi M$	$\nabla \cdot D = 4\pi\rho$ $\nabla \times H = 4\pi J + \frac{\partial D}{\partial t}$ $\nabla \times E + \frac{\partial B}{\partial t} = 0$ $\nabla \cdot B = 0$	$E + v \times B$
Gaussian	1	1	$D = E + 4\pi P$ $H = B - 4\pi M$	$\nabla \cdot D = 4\pi\rho$ $\nabla \times H = \frac{4\pi}{c}J + \frac{1}{c}\frac{\partial D}{\partial t}$ $\nabla \times E + \frac{1}{c}\frac{\partial B}{\partial t} = 0$ $\nabla \cdot B = 0$	$E + v \times B$ $\frac{v}{c}$
Heaviside-Lorentz	1	1	$D = E + P$ $H = B - M$	$\nabla \cdot D = \rho$ $\nabla \times H = \frac{1}{c}\left(J + \frac{\partial D}{\partial t}\right)$ $\nabla \times E + \frac{1}{c}\frac{\partial B}{\partial t} = 0$ $\nabla \cdot B = 0$	$E + v \times B$ $\frac{v}{c}$
Rationalized MKSA	$\frac{10^7}{4\pi c^2}$ $(l^2t^4m^{-1}l^{-3})$	$4\pi \times 10^{-7}$ $(mlT^{-2}t^{-2})$	$D = \epsilon_0 E + P$ $H = \frac{1}{\mu_0}B - M$	$\nabla \cdot D = \rho$ $\nabla \times H = J + \frac{\partial D}{\partial t}$ $\nabla \times E + \frac{\partial B}{\partial t} = 0$ $\nabla \cdot B = 0$	$E + v \times B$

Table 3
Conversion Table for Symbols and Formulas

The symbols for mass, length, time, force, and other not specifically electromagnetic quantities are unchanged. To convert any equation in Gaussian variables to the corresponding equation in MKSA quantities, on both sides of the equation replace the relevant symbols listed below under "Gaussian" by the corresponding "MKSA" symbols listed on the right. The reverse transformation is also allowed. Since the length and time symbols are unchanged, quantities which differ dimensionally from one another only by powers of length and/or time are grouped together where possible.

Quantity	Gaussian	MKSA
Velocity of light	c	$(\mu_0 \epsilon_0)^{-1/2}$
Electric field (potential, voltage)	$\mathbf{E}(\Phi, V)$	$\sqrt{4\pi\epsilon_0} \mathbf{E}(\Phi, V)$
Displacement	\mathbf{D}	$\sqrt{\frac{4\pi}{\epsilon_0}} \mathbf{D}$
Charge density (charge, current density, current, polarization)	$\rho(q, \mathbf{J}, I, \mathbf{P})$	$\frac{1}{\sqrt{4\pi\epsilon_0}} \rho(q, \mathbf{J}, I, \mathbf{P})$
Magnetic induction	\mathbf{B}	$\sqrt{\frac{4\pi}{\mu_0}} \mathbf{B}$
Magnetic field	\mathbf{H}	$\sqrt{4\pi\mu_0} \mathbf{H}$
Magnetization	\mathbf{M}	$\sqrt{\frac{\mu_0}{4\pi}} \mathbf{M}$
Conductivity	σ	$\frac{\sigma}{4\pi\epsilon_0}$
Dielectric constant	ϵ	$\frac{\epsilon}{\epsilon_0}$
Permeability	μ	$\frac{\mu}{\mu_0}$
Resistance (impedance)	$R(Z)$	$4\pi\epsilon_0 R(Z)$
Inductance	L	$4\pi\epsilon_0 L$
Capacitance	C	$\frac{1}{4\pi\epsilon_0} C$

Table 4
Conversion Table for Given Amounts of a Physical Quantity

The table is arranged so that a given amount of some physical quantity, expressed as so many MKSA or Gaussian units of that quantity, can be expressed as an equivalent number of units in the other system. Thus the entries in each row stand for the same amount, expressed in different units. All factors of 3 (apart from exponents) should, for accurate work, be replaced by (2.99792456) , arising from the numerical value of the velocity of light. For example, in the row for displacement (D), the entry $(12\pi \times 10^5)$ is actually $(2.99792 \times 4\pi \times 10^5)$. Where a name for a unit has been agreed on or is in common usage, that name is given. Otherwise, one merely reads so many Gaussian units, or MKSA or SI units.

Physical Quantity	Symbol	Rationalized MKSA		Gaussian
Length	l	1 meter (m)	10^2	centimeters (cm)
Mass	m	1 kilogram (kg)	10^3	grams (gm)
Time	t	1 second (sec)	1	second (sec)
Frequency	ν	1 hertz (Hz)	1	hertz (Hz)
Force	F	1 newton	10^5	dynes
Work	W	1 joule	10^7	ergs
Energy	U			
Power	P	1 watt	10^7	ergs sec ⁻¹
Charge	q	1 coulomb	3×10^9	statcoulombs
Charge density	ρ	1 coul m ⁻³	3×10^3	statcoul cm ⁻³
Current	I	1 ampere (amp)	3×10^9	statamperes
Current density	J	1 amp m ⁻²	3×10^5	statamp cm ⁻²
Electric field	E	1 volt m ⁻¹	$\frac{1}{3} \times 10^{-4}$	statvolt cm ⁻¹
Potential	Φ, V	1 volt	$\frac{1}{300}$	statvolt
Polarization	P	1 coul m ⁻²	3×10^5	dipole moment cm ⁻³
Displacement	D	1 coul m ⁻²	$12\pi \times 10^5$	statvolt cm ⁻¹ (statcoul cm ⁻²)
Conductivity	σ	1 mho m ⁻¹	9×10^9	sec ⁻¹
Resistance	R	1 ohm	$\frac{1}{9} \times 10^{-11}$	sec cm ⁻¹
Capacitance	C	1 farad	9×10^{11}	cm
Magnetic flux	ϕ, F	1 weber	10^8	gauss cm ² or maxwells
Magnetic induction	B	1 tesla	10^4	gauss
Magnetic field	H	1 ampere-turn m ⁻¹	$4\pi \times 10^{-3}$	oersted
Magnetization	M	1 ampere m ⁻¹	10^{-3}	magnetic moment cm ⁻³
*Inductance	L	1 henry	$\frac{1}{9} \times 10^{-11}$	

* There is some confusion prevalent about the unit of inductance in Gaussian units. This stems from the use by some authors of a modified system of Gaussian units in which current is measured in electromagnetic units, so that the connection between charge and current is $I_m = (1/c)(dq/dt)$. Since inductance is defined through the induced voltage $V = L(dI/dt)$ or the energy $U = \frac{1}{2}LI^2$, the choice of current defined in Section 2

formula in such a way that omission of the factor in square brackets in the equation will yield the equivalent MKSA equation (provided all symbols are reinterpreted as MKSA variables).

Tables 3 and 4 are designed for general use in conversion from one system to the other. Table 3 is a conversion scheme for *symbols and equations* which allows the reader to convert any equation from the Gaussian system to the MKSA system and vice versa. Simpler schemes are available for conversion only *from* the MKSA system *to* the Gaussian system, and other general schemes are possible. But by keeping all mechanical quantities unchanged, the recipe in Table 3 allows the straightforward conversion of quantities which arise from an interplay of electromagnetic and mechanical forces (e.g., the fine structure constant $e^2/\hbar c$ and the plasma frequency $\omega_p^2 = 4\pi ne^2/m$) without additional considerations. Table 4 is a conversion table for units to allow the reader to express a given amount of any physical entity as a certain number of MKSA units or cgs-Gaussian units.

means that our Gaussian unit of inductance is equal in magnitude and dimensions ($r^2 I^{-1}$) to the electrostatic unit of inductance. The electromagnetic current I_m is related to our Gaussian current I by the relation $I_m = (1/c)I$. From the energy definition of inductance we see that the electromagnetic inductance L_m is related to our Gaussian inductance L through $L_m = c^2 L$. Thus L_m has the dimensions of length. The modified Gaussian system generally uses the electromagnetic unit of inductance, as well as current. Then the voltage relation reads $V = (L_m/c)(dI_m/dt)$. The numerical connection between units of inductance is

$$1 \text{ henry} = \frac{1}{9} \times 10^{-11} \text{ Gaussian (es) unit} = 10^9 \text{ emu}$$

Where to Find Key Material on Special Functions

SPHERICAL

Legendre polynomials $P_l(x)$	87-90
Associated Legendre functions $P_l^m(x)$	98
Spherical harmonics $Y_{lm}(\theta, \phi)$	99-100

CYLINDRICAL

Bessel functions $J_\nu(x)$, $N_\nu(x)$	104-5
Modified Bessel functions $I_\nu(x)$, $K_\nu(x)$	107-8
Spherical Bessel functions $j_l(x)$, $n_l(x)$, $h_l^{(1,2)}(x)$	740-1
Roots of $J_m(x) = 0$	105
Roots of $J'_m(x) = 0$	356
Identities involving Bessel functions	118, 125, 131, 203
Airy integrals, connection to Bessel functions	323, 674

ORTHOGONAL FUNCTION EXPANSIONS

Bessel function (finite interval in ρ)	106, 130
Bessel function (infinite interval in ρ)	109-10
Eigenfunction, of Green function	119-20
Fourier series	67
Fourier integral	67-8
Legendre polynomial	88-9
Spherical harmonic	100

Explicit Forms of Vector Operations

Let $\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3$ be orthogonal unit vectors associated with the coordinate directions specified in the headings on the left, and A_1, A_2, A_3 be the corresponding components of \mathbf{A} . Then

Cartesian
($x_1, x_2, x_3 = x, y, z$)

$$\begin{aligned}\nabla\psi &= \mathbf{e}_1 \frac{\partial\psi}{\partial x_1} + \mathbf{e}_2 \frac{\partial\psi}{\partial x_2} + \mathbf{e}_3 \frac{\partial\psi}{\partial x_3} \\ \nabla \cdot \mathbf{A} &= \frac{\partial A_1}{\partial x_1} + \frac{\partial A_2}{\partial x_2} + \frac{\partial A_3}{\partial x_3} \\ \nabla \times \mathbf{A} &= \mathbf{e}_1 \left(\frac{\partial A_3}{\partial x_2} - \frac{\partial A_2}{\partial x_3} \right) + \mathbf{e}_2 \left(\frac{\partial A_1}{\partial x_3} - \frac{\partial A_3}{\partial x_1} \right) + \mathbf{e}_3 \left(\frac{\partial A_2}{\partial x_1} - \frac{\partial A_1}{\partial x_2} \right) \\ \nabla^2 \psi &= \frac{\partial^2 \psi}{\partial x_1^2} + \frac{\partial^2 \psi}{\partial x_2^2} + \frac{\partial^2 \psi}{\partial x_3^2}\end{aligned}$$

Cylindrical
(ρ, ϕ, z)

$$\begin{aligned}\nabla\psi &= \mathbf{e}_1 \frac{\partial\psi}{\partial \rho} + \mathbf{e}_2 \frac{1}{\rho} \frac{\partial\psi}{\partial \phi} + \mathbf{e}_3 \frac{\partial\psi}{\partial z} \\ \nabla \cdot \mathbf{A} &= \frac{1}{\rho} \frac{\partial}{\partial \rho} (\rho A_1) + \frac{1}{\rho} \frac{\partial A_2}{\partial \phi} + \frac{\partial A_3}{\partial z} \\ \nabla \times \mathbf{A} &= \mathbf{e}_1 \left(\frac{1}{\rho} \frac{\partial A_3}{\partial \phi} - \frac{\partial A_2}{\partial z} \right) + \mathbf{e}_2 \left(\frac{\partial A_1}{\partial z} - \frac{\partial A_3}{\partial \rho} \right) + \mathbf{e}_3 \left(\frac{\partial}{\partial \rho} (\rho A_2) - \frac{\partial A_1}{\partial \phi} \right) \\ \nabla^2 \psi &= \frac{1}{\rho} \frac{\partial}{\partial \rho} \left(\rho \frac{\partial\psi}{\partial \rho} \right) + \frac{1}{\rho^2} \frac{\partial^2 \psi}{\partial \phi^2} + \frac{\partial^2 \psi}{\partial z^2}\end{aligned}$$

Spherical
(r, θ, ϕ)

$$\begin{aligned}\nabla\psi &= \mathbf{e}_1 \frac{\partial\psi}{\partial r} + \mathbf{e}_2 \frac{1}{r} \frac{\partial\psi}{\partial \theta} + \mathbf{e}_3 \frac{1}{r \sin \theta} \frac{\partial\psi}{\partial \phi} \\ \nabla \cdot \mathbf{A} &= \frac{1}{r^2} \frac{\partial}{\partial r} (r^2 A_1) + \frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} (\sin \theta A_2) + \frac{1}{r \sin \theta} \frac{\partial A_3}{\partial \phi} \\ \nabla \times \mathbf{A} &= \mathbf{e}_1 \frac{1}{r \sin \theta} \left[\frac{\partial}{\partial \theta} (\sin \theta A_3) - \frac{\partial A_2}{\partial \phi} \right] \\ &\quad + \mathbf{e}_2 \left[\frac{1}{r \sin \theta} \frac{\partial A_1}{\partial \phi} - \frac{1}{r} \frac{\partial}{\partial r} (r A_3) \right] + \mathbf{e}_3 \frac{1}{r} \left[\frac{\partial}{\partial r} (r A_2) - \frac{\partial A_1}{\partial \theta} \right] \\ \nabla^2 \psi &= \frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial\psi}{\partial r} \right) + \frac{1}{r^2 \sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial\psi}{\partial \theta} \right) + \frac{1}{r^2 \sin^2 \theta} \frac{\partial^2 \psi}{\partial \phi^2} \\ &\quad \left[\text{Note that } \frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial\psi}{\partial r} \right) \equiv \frac{1}{r} \frac{\partial^2}{\partial r^2} (r\psi) \right]\end{aligned}$$
